# Pharmacological Properties and Biological Functions of the GPR17 Receptor, a Potential Target for Neuro-Regenerative Medicine

Marta Fumagalli, Davide Lecca, Giusy T. Coppolino,  
Chiara Parravicini, and Maria P. Abbracchio

## Abstract

In 2006, cells heterologously expressing the “orphan” receptor GPR17 were shown to acquire responses to both uracil nucleotides and cysteinyl-leukotrienes, two families of signaling molecules accumulating in brain or heart as a result of hypoxic/traumatic injuries. In subsequent years, evidence of GPR17 key role in oligodendrogenesis and myelination has highlighted it as a “model receptor” for new therapies in demyelinating and neurodegenerative diseases. The apparently contrasting evidence in the literature about the role of GPR17 in promoting or inhibiting myelination can be due to its transient expression in the intermediate stages of differentiation, exerting a pro-differentiating function in early oligodendrocyte precursor cells (OPCs), and an inhibitory role in late stage maturing cells. Meanwhile, several papers extended the initial data on GPR17 pharmacology, highlighting a “promiscuous” behavior of this receptor; indeed, GPR17 is able to respond to other emergency signals like oxysterols or the pro-inflammatory cytokine SDF-1, underlying GPR17 ability to adapt its responses to changes of the surrounding extracellular milieu, including damage conditions. Here, we analyze the available literature on GPR17, in an attempt to summarize its emerging biological roles and pharmacological properties.

Marta Fumagalli and Davide Lecca contributed equally to this work.

**1 Introduction: The History of GPR17**

62 In 2006, a paper was published where it was  
63 demonstrated that cells heterologously  
64 expressing the “orphan” receptor GPR17 (i.e., a  
65 molecularly identified, 339 amino acid-long  
66 G<sub>i</sub>-protein-coupled receptor that still lacked a  
67 defined ligand) acquired responses to both uracil  
68 nucleotides (such as UDP, UDP-glucose,  
69 UDP-galactose) and cysteinyl-leukotrienes  
70 (cysLTs, like LTC<sub>4</sub> and LTD<sub>4</sub>) (Ciana et al.  
71 2006), two chemically unrelated families of sig-  
72 naling molecules that are known to massively  
73 accumulate in organs like the brain or the heart  
74 as a result of hypoxic/traumatic injuries. Uracil  
75 nucleotides and cysLTs were already known to  
76 exert multiple biological effects via the

activation of separate G-protein-coupled 77  
receptors (GPCRs): the eight recognized P2Y 78  
receptor subtypes (the P2Y<sub>1,2,4,6,11,12,13,14</sub> 79  
receptors, (Abbracchio et al. 2006) and the two 80  
CysLT1 and CysLT2 receptors. Interestingly, the 81  
GPR17 sequence had been originally described 82  
as the result of a cloning strategy based on the 83  
use of RT-PCR degenerate oligonucleotide 84  
primers designed on the sequences of the P2Y<sub>1</sub> 85  
and P2Y<sub>2</sub> receptors, with the final aim of 86  
identifying new members of this receptor family 87  
(Blasius et al. 1998). GPR17 was later found to 88  
be at an intermediate structural and phylogenetic 89  
position between already known P2Y and CysLT 90  
receptors, and GPR99, recently proposed as the 91  
third CysLT receptor (also known as 92  
2-oxoglutarate receptor 1, OXGR1) (Kanaoka 93  
et al. 2013) (Fig. 1), in the so called “purine 94  
receptor cluster” of class A GPCRs (Fredriksson 95  
et al. 2003). GPR17 also emerged as represented 96  
the closest receptor to a common ancestor that, 97  
during evolution, could have generated both P2Y 98  
and CysLT receptors (Ciana et al. 2006; 99  
Parravicini et al. 2008; Parravicini et al. 2010). 100  
To further highlight GPR17 structural similarity 101  
to the other members of the P2Y family, a partial 102  
sequence of the rat receptor was initially 103  
identified from rat striatum by employing oligo- 104  
nucleotide primers specifically designed on the 105  
sequence of human P2Y<sub>11</sub> (Lecca and 106  
Abbracchio 2008). Of note, a human GPR17 107  
long splice variant encoding a receptor with a 108  
28-amino acid longer NH<sub>2</sub> terminal (for a total 109  
of 367 amino acids instead of 339) had been also 110  
identified in very early studies aimed at discov- 111  
ering new members of the chemokine receptor 112  
family (in this respect, see also Sect. 2.1) 113  
(Blasius et al. 1998). Genomic analysis revealed 114  
a three-exon structure of the hGPR17 gene, with 115  
two putative open reading frames. While the 116  
“short isoform” derives from splicing of the 117

**Fig. 1** Phylogenetic tree illustrating the relationship of GPR17 to selected structurally related class-A GPCRs. The evolutionary relationship analysis is based on a multiple sequence alignment performed on homologous GPCR sequences using TM-Coffee, a module of the T-Coffee package optimized for transmembrane proteins (Chang et al. 2012). Receptors belonging to the same

family are clustered according to the following color code: *grey* for purinergic receptors (P2Y), *orange* for cysteinyl-leukotriene receptors (CysLT), *light green* for chemokine receptors (CXCRn, CCRn, XCRn), *emerald green* for Epstein-Barr virus-induced G-protein coupled receptor 2 (EBI2), *sky blue* for 2-Oxoglutarate receptor 1 (OXGR1/GPR99), *apple green* for GPR17

118 second exon, the “long one” contains all three  
 119 exons of the hGPR17 gene, leading to a transcript  
 120 which is 1104 bp in length (Blasius et al. 1998;  
 121 Pugliese et al. 2009). Interestingly, quantitative  
 122 gene expression studies revealed that GPR17  
 123 short isoform is expressed more abundantly in  
 124 the brain than the long one (a tenfold increase),  
 125 whereas the opposite was observed in heart and  
 126 kidney. Pharmacological profile of the long iso-  
 127 form also showed that some differences exist  
 128 between the two GPR17 receptor isoforms  
 129 (Pugliese et al. 2009; Benned-Jensen and  
 130 Rosenkilde 2010).

In 2006, there were already papers reporting  
 functional interactions between “classical” P2Y  
 and CysLT receptors. For example, under some  
 conditions, the CysLT1 receptor antagonist  
 montelukast effectively antagonized the  
 responses evoked by purinergic P2Y receptors  
 (Capra et al. 2005; Mamedova et al. 2005). Con-  
 versely, the P2Y<sub>12</sub> receptor had been reported to  
 be also activated by LTE<sub>4</sub> (Paruchuri et al. 2009),  
 suggesting the existence of some kind of ligand/  
 receptor promiscuity between the P2Y and  
 CysLT receptor families. On this basis, the iden-  
 tification of GPR17 as the first dual member of  
 the “purine receptor cluster” able to respond to

145 both purinergic and cysLT ligands (Ciana et al.  
 146 2006) represented the demonstration of a further  
 147 level of interaction between these two chemi-  
 148 cally unrelated, but functionally interconnected,  
 149 systems. Later studies extended the response pro-  
 150 file of this receptor to other classes of endoge-  
 151 nous “emergency” molecules connected to  
 152 oxidative stress, neuroinflammation and  
 153 neurodegeneration, i.e., oxysterols and chemo-  
 154 kine stromal derived factor-1 (SDF-1)  
 155 (Parravicini et al. 2016), further highlighting the  
 156 promiscuous behaviour of GPR17. Of note, a  
 157 phylogenetic analysis among structurally related  
 158 class-A GPCRs (Parravicini et al. 2008, 2010,  
 159 2016; Sensi et al. 2014), suggest that, besides  
 160 P2Y and CysLT receptors, GPR17 holds a tight  
 161 evolutionary relationship also with chemokine  
 162 receptors and Epstein-Barr virus-induced  
 163 G-protein coupled receptor 2 (EBI2) (Fig. 1).  
 164 The possibility that GPR17 can be activated by  
 165 diverse family of ligands underlines the rele-  
 166 vance of a new transversal signaling mechanism  
 167 that synchronizes all these emergency molecules  
 168 and their receptors under specific neurodegener-  
 169 ative conditions. Such a high promiscuity in  
 170 receptor behaviour is often found in receptors  
 171 involved in immunological responses and may,  
 172 at least in part, depend on GPR17 ability to form  
 173 dimers with other related receptors, thus widen-  
 174 ing the array of pharmacological responses (see  
 175 also Sect. 2.2.1).

176 In subsequent years, new data have revealed a  
 177 key role for GPR17 in oligodendrogenesis and  
 178 myelination (Lecca et al. 2008; Chen et al. 2009).  
 179 However, while some authors have provided evi-  
 180 dence for a stimulatory role of GPR17 in the  
 181 specification and maturation of oligodendrocyte  
 182 precursor cells (OPCs), some others have pro-  
 183 posed an inhibitory role. Here, we aim at  
 184 analyzing all the available literature on GPR17  
 185 in an attempt to provide an overview of the  
 186 different biological and pharmacological data  
 187 emerged from all these papers.

## 2 GPR17 Characterization 188

### 2.1 Receptor Structure, Amino Acid Homology with Phylogenetically Related GPCRs and Binding Sites 189-191

GPR17 displays the typical 7-transmembrane (TM) domain topology of GPCRs, with an amino acid identity with the known P2Y and CysLT receptors between 21 and 48% (Abbracchio et al. 2006; Lecca and Abbracchio 2008). All these receptors show partial or complete conservation of a H-X-X-R/K amino acid motif in TM6 (and also of a K-E-X-X-L motif in TM7, in the case of P2Y<sub>12</sub>, P2Y<sub>13</sub>, P2Y<sub>14</sub>) that are important for ligand recognition and have been proposed to represent specific molecular signatures for these receptors (Lecca and Abbracchio 2008) (see also below). Homology Modelling (HM) studies combined with other *in silico* tools have been performed to raise hypothesis on the molecular interaction between GPR17 and its putative endogenous ligands (Parravicini et al. 2008, 2010; Calleri et al. 2010), as well as to identify new potential ligands (Eberini et al. 2011) (see also Sect. 2.2.2). In these studies, *in silico* receptor modeling was performed using different templates, according to the progressive availability of new high-resolution GPCR structures. Starting from bovine rhodopsin, that, since 2000, has represented for many years the only atomistic scaffold for the structural investigation of GPCRs, the recent explosion in the resolution of GPCR crystal structures has given access to detailed structural information previously unavailable, allowing the construction of more and more accurate GPR17 models (Fig. 2).

For example, in 2010, crystallization of human CXCR4 (Wu et al. 2010) provided a significant improvement in the accuracy of GPR17 modelling because this structure enabled to reliably describe the extracellular regions of the receptor, especially extracellular loop 2 (ECL2) and the disulphide bridge linking the N-terminal to ECL3, known to be crucial in ligand molecular recognition (Wheatley et al. 2012), but for which none of the earlier templates was suitable. More

**Fig. 2 Three-dimensional homology model of the human GPR17.** Topological domains are represented as ribbon and coloured according to their secondary structure: *magenta* for alpha-helices; *yellow* for beta-sheets; *white* for loops and grey for turns

233 recently, modelling of GPR17 has been further  
 234 improved thanks to the atomic resolution of the  
 235 structures of two members of the P2Y receptor  
 236 family: the human P2Y<sub>12</sub> (Zhang et al. 2014) and  
 237 P2Y<sub>1</sub> (Zhang et al. 2015).

238 Globally, all the *in silico* results on the short  
 239 isoform of GPR17 suggest that its nucleotide  
 240 binding pocket is similar to that described for  
 241 the other P2Y receptors (including the TM6  
 242 HXXR/K motif designated to accommodate the  
 243 phosphate moieties of nucleotide ligands  
 244 (Parravicini et al. 2008; Jiang et al. 1997), and  
 245 that this site is also shared by other small  
 246 molecules identified as GPR17 ligands, including  
 247 oxysterols and new synthetic compounds (Sensi  
 248 et al. 2014; Eberini et al. 2011). According to  
 249 these studies, also the nucleotide-derivative  
 250 antagonist cangrelor binds to the same binding  
 251 pocket, behaving as a competitive antagonist for  
 252 orthosteric ligands.

253 In both P2Y and CysLT1 and CysLT2  
 254 receptors, ligand binding is critically dependent  
 255 on the basic Arginine residue belonging to the

conserved TM6 motif (Parravicini et al. 2010; 256  
 Temporini et al. 2009). Computational studies 257  
 suggested that this also holds true for Arg255 of 258  
 GPR17 (Parravicini et al. 2008). To assess the 259  
 actual role of this residue in receptor binding, this 260  
 basic amino acid was mutated to isoleucine, and 261  
 an *in silico* mutant GPR17 receptor (R255I) was 262  
 generated. Using steered molecular dynamics 263  
 simulations (SMD), forced unbinding of the 264  
 endogenous ligand UDP from both wild type 265  
 (WT) and R255I receptor models of GPR17 266  
 was modeled *in silico*. The energy required to 267  
 unbind UDP from the nucleotide binding pocket 268  
 of GPR17 was higher for the WT than for the 269  
 mutated R255I receptor, and the exit of the 270  
 ligand from its intracellular cavities occurred 271  
 earlier in the R255I model compared to the WT 272  
 receptor. Generation and expression of the 273  
 mutated receptor in 1321N1 cells confirmed 274  
 also *in vitro* that the mutation was not silent 275  
 (Calleri et al. 2010). 276

Besides the orthosteric binding site, *in silico* 277  
 studies suggested that GPR17 also possesses an 278  
 “accessory” binding site in a region formed by 279  
 extracellular loops ECL2, ECL3 and the N- 280  
 terminal, which also faces the extracellular space. 281  
 This external accessory binding site could guide 282  
 small agonist ligands to the deeper principal 283  
 binding site in a multistep mechanism of activa- 284  
 tion. Thanks to further *in silico* investigations, 285  
 that showed the possibility of GPR17 to be 286  
 stimulated also by a large peptide ligand such 287  
 as SDF-1, the extracellular recognition site has 288  
 been extensively characterized and GPR17 rec- 289  
 ognition mechanism has been compared to those 290  
 of some peptide receptors (Parravicini et al. 291  
 2016), in which a two-step model of receptor 292  
 activation, passing through both an extracellular 293  
 and a TM binding site, has been proposed 294  
 (Rajagopalan and Rajarathnam 2004). 295

296 Due to the intrinsic inaccuracy of the standard  
 297 template-based HM techniques in predicting  
 298 conformations of highly flexible and unaligned  
 299 loop sequences in absence of adequate templates,  
 300 no modeling studies are yet available for the long  
 301 isoform of GPR17. Nevertheless, we can specu-  
 302 late that the N-terminal may influence the bind-  
 303 ing affinity of nucleotide agonists via a different

304 conformation of the external accessory binding  
305 site, resulting in a slightly different pharmaco-  
306 logical profile of the long isoform with respect to  
307 the short one (Pugliese et al. 2009).

## 308 **2.2 Pharmacology and Signaling** 309 **Pathways**

### 310 **2.2.1 Putative Endogenous Ligands** 313 **and Transduction Systems**

314 In the initial studies, only GPR17 short isoform  
315 has been characterized, and both the human, rat  
316 (Ciana et al. 2006) and the previously unidenti-  
317 fied mouse GPR17 receptors (Lecca and Ceruti  
318 2008) were shown to respond to UDP,  
319 UDP-glucose, UDP-galactose and LTC<sub>4</sub> and  
320 LTD<sub>4</sub>, with comparable profiles that were highly  
321 conserved across species (the chemical structures  
322 of UDP-glucose and LTD<sub>4</sub> are reported in  
323 Fig. 3). Interestingly, the concentration ranges  
324 at which uracil nucleotides and cysLTs activated  
325 GPR17 (i.e.,  $\mu$ M and nM ranges, respectively)  
326 were fully consistent with those necessary for  
327 these endogenous ligands to activate their  
328 already known cognate P2Y and CysLT  
329 receptors (Abbracchio et al. 2006; Brink et al.  
330 2003). Very similar agonist responses were  
331 detected in a number of different cell lines  
332 (1321N1, CHO, COS-7, HEK-293 cells). The  
333 1321N1 cells was the most appropriate cells to  
334 test GPR17 responses, since they are one of the  
335 few cell lines that do not endogenously express  
336 any functional purinergic or CysLT receptors.  
337 Responses were highly specific, since no  
338 response was ever found in cells transfected  
339 with the empty vector. The antagonist response  
340 profile of GPR17 was also rather peculiar. Acti-  
341 vation by uracil nucleotides was reversed by  
342 some typical purinergic antagonists like the  
343 P2Y<sub>1</sub> antagonist MRS2179 or the P2Y<sub>12</sub> antago-  
344 nist cangrelor (Fig. 3). Conversely, responses to  
345 cysLTs were inhibited by typical CysLT receptor  
346 antagonists like the already marketed drug  
347 montelukast (Fig. 3) and pranlukast (Ciana  
348 et al. 2006).

349 GPR17 responses were demonstrated by using  
350 [<sup>35</sup>S]GTP $\gamma$ S binding, a typical functional assay

for agonists acting at G<sub>i</sub> coupled receptors 351  
(Kotani et al. 2001; Marteau et al. 2003; 352  
Fumagalli et al. 2004). Under some 353  
circumstances, activation of GPR17 could also 354  
increase intracellular calcium levels via a phos- 355  
pholipase C mediated pathway; however, this 356  
effect occurred only in about 30% of 1321N1 357  
transfected cells, suggesting preferential cou- 358  
pling to the adenylyl cyclase pathway (Ciana 359  
et al. 2006). In subsequent studies, GPR17 pecu- 360  
liar profile was confirmed in many other distinct 361  
assays independently performed in different 362  
laboratories. Concentration-dependent inhibition 363  
of forskolin-stimulated adenylyl cyclase was also 364  
shown in oligodendrocyte precursor cells 365  
(OPCs), the cell type natively expressing 366  
GPR17 at highest levels (Fumagalli et al. 367  
2011a) (Table 1). Inhibition of cAMP was fully 368  
counteracted by the same antagonists utilized in 369  
the [<sup>35</sup>S]GTP $\gamma$ S binding. In 2009, another paper 370  
appeared where, in GPR17 expressing 1321N1 371  
cells, enhancement of an outward rectifying K<sup>+</sup> 372  
current was shown upon addition of either uracil 373  
nucleotides or cysLTs (Pugliese et al. 2009). 374  
These effects were blocked by MRS2179, 375  
cangrelor and montelukast. A few years later, 376  
these same authors showed that similar delayed 377  
rectifier K<sup>+</sup> currents were stimulated in a concen- 378  
tration dependent manner by GPR17 ligands in a 379  
subpopulation of OPCs and 380  
pre-oligodendrocytes, but not in terminally 381  
mature cells, fully in line with the transient 382  
expression of GPR17 during OPC specification 383  
(in this respect, see also Sect. 3.1.1) (Coppi et al. 384  
2013). This effect was blocked by MRS2179 and 385  
cangrelor and sensitive to the K<sup>+</sup> channel blocker 386  
tetraethyl-ammonium. Importantly, the latter 387  
also inhibited oligodendrocyte maturation, to 388  
support previous literature data on the impor- 389  
tance of these currents in OPC differentiation. 390

Fewer studies are available on hGPR17 long 391  
isoform. In the electrophysiological study 392  
already mentioned above, no significant 393  
differences between the short and long isoforms 394  
were detected (Pugliese et al. 2009). In 2010, 395  
Bened-Jensen and Rosenkilde independently 396  
confirmed the ability of heterologously 397  
expressed GPR17 to respond to uracil 398

**Fig. 3** Chemical structures of endogenous and synthetic compounds reported to bind GPR17. CAS Registry number of synthetic ligands are the following:

MDL29,951 #130798–51-5; ASN-1: #483283–39-2. For SDF-1, a representative X-ray structure deposited in the Protein Data Bank is reported (Pdb code: 1QG7)

407 2008) and in frontal affinity chromatography-  
 408 mass spectrometry (FAC-MS) studies (Calleri  
 409 et al. 2010; Temporini et al. 2009). Much lower  
 410 potencies to uracil nucleotides were observed for  
 411 the long receptor isoform, with a 50–170 fold  
 412 increase in EC<sub>50</sub> (Bened-Jensen and Rosenkilde  
 413 2010). Moreover, no responses to cysLTs were  
 414 detected either on the short or long isoform, nor  
 415 were cysLTs able to induce GPR17 removal  
 416 from the membrane and internalization. This is  
 417 in contrast with subsequent studies on cells  
 418 natively expressing the receptor (Fratangeli  
 419 et al. 2013) (see below). This may depend on  
 420 differences in the conformation/ability of the  
 421 recombinant receptor to respond to agonists com-  
 422 pared to the native one, as well as on the fact that,  
 423 in heterologously expressing systems, constitu-  
 424 tive activity of transfected receptors may

significantly alter ligand behavior (Kenakin 425  
 2001; Im 2013) (see also Conclusions). In this 426  
 respect, Benned-Jensen and Rosenkilde indeed 427  
 reported a notable constitutive activation of 428  
 recombinant GPR17 resulting in potent inhibi- 429  
 tion of forskolin stimulated adenylyl cyclase in 430  
 the absence of any endogenous ligand (Bened- 431  
 Jensen and Rosenkilde 2010). 432

At the same time, another paper suggested 433  
 GPR17 as a negative regulator of the CysLT1 434  
 receptor (Maekawa et al. 2009). This effect was 435  
 proposed to depend on the formation of a 436  
 CysLT1-GPR17 heteromer, as suggested by 437  
 co-immunoprecipitation studies in CHO cells. 438  
 The interaction between GPR17 and CysLT1 439  
 was further confirmed in primary human mono- 440  
 cyte cells and in a rodent knock out GPR17 441  
 model, thus extending to GPR17 the previously 442

443 reported interaction and promiscuity between  
444 different members of the “purine receptor cluster”.  
445 These data indicate that, besides working on  
446 its own, GPR17 may also modify the function of  
447 other related receptors by the formation of  
448 heteromers.

449 In 2010, the first paper describing the  
450 characteristics of GPR17 in a *native* system (rat  
451 pheochromocytoma PC12 cells) was published  
452 (Daniele et al. 2010) (Table 1). GPR17 was not  
453 expressed in undifferentiated PC12 cells but was  
454 specifically induced by a 10-day NGF treatment,  
455 suggesting a role in the control of neuronal differentiation.  
456 Both UDP-glucose and LTD<sub>4</sub>  
457 induced a significant pro-survival effect on  
458 PC12 cells. By *in vitro* silencing experiments  
459 with small interfering RNAs and by using receptor  
460 antagonists, these effects were confirmed to  
461 be mediated by the selective activation of  
462 GPR17. In differentiated PC12 cells,  
463 UDP-glucose and LTD<sub>4</sub> caused a significant  
464 increase in extracellular signal-regulated kinases  
465 1 and 2 (ERK1/2) phosphorylation. ERK activation  
466 induced by the two agonists occurred with  
467 different kinetics: LTD<sub>4</sub> induced a transient ERK  
468 activation that returned to basal value within  
469 120 min. In contrast, ERK phosphorylation  
470 induced by UDP-glucose was maintained over  
471 basal values for 120 min and the activation kinetics  
472 appeared to be biphasic with two peaks, one  
473 at 15 and the other one at 120 min. In addition,  
474 incubation of cells with the purinergic antagonist  
475 cangrelor completely counteracted UDP-glucose  
476 effects at all tested incubation times (Daniele  
477 et al. 2010). These data confirmed the responses  
478 to uracil nucleotides and cysLTs already seen on  
479 the recombinant receptors, and suggested, for the  
480 first time, that endogenous GPR17 ligands can  
481 couple to distinct G proteins and intracellular  
482 pathways, a finding that was later confirmed by  
483 other studies (Hennen et al. 2013; Daniele et al.  
484 2014). The signaling pathways of native GPR17  
485 are summarized in Table 1.

486 In 2011, in another study that independently  
487 confirmed the purinergic component of GPR17,  
488 Buccioni and coworkers (Buccioni et al. 2011)  
489 exploited an innovative and non-radioactive

functional cAMP assay to monitor GPR17 activation  
(and the effects of various ligands) through changes  
in intracellular cAMP concentrations by using a mutant  
form of Photinus pyralis luciferase into which a cAMP-  
binding protein moiety had been inserted (GloSensor  
cAMP reagent). In HEK293 cells stably transfected  
with the GloSensor reagent, transient expression of  
hGPR17 resulted in the appearance of highly specific  
concentration-dependent responses to both UDP,  
UDP-glucose and UDP-galactose and to a series of  
UDP and ATP derivatives that behaved as either  
agonist or antagonists, with EC<sub>50</sub> values that were  
very similar to those obtained in parallel on [<sup>35</sup>S]  
GTPγS binding. In this system, cysLTs were not  
tested, due to the high constitutive expression of  
traditional CysLT receptors in the HEK293 cells  
(Ciana et al. 2006; Buccioni et al. 2011).

## 2.2.2 GPR17 Non-conventional Ligands

In the last years, the increasing number of class-A  
GPCR solved structures allowed the scientific  
community to recognize some common features  
that are crucial for their operability (Levit et al.  
2014); however, these studies also revealed an  
unexpected heterogeneity and complexity in  
GPCR recognition, challenging the classical  
pharmacology paradigms of the ‘monogamous’  
interaction between a specific class of natural  
ligands and a single GPCR (Haupt et al. 2013).  
In line with the growing promiscuity of GPCRs,  
ligand dependent transactivation has been  
demonstrated for GPR17, already known as a  
“dual” receptor: similarly to EB12 (Hannedouche  
et al. 2011; Liu et al. 2011a), and the CXC  
chemokine receptor 2 (CXCR2) (Raccosta et al.  
2013). Specifically, it was shown that, GPR17  
could act as a molecular target for oxysterols,  
oxidized derivative of cholesterol that, in the  
CNS, are involved in activities not strictly  
associated with cholesterol metabolism. Of  
note, these activities are particularly relevant  
for neurodegenerative disorders, including  
demyelinating (Raccosta et al. 2013; Garenc

537 et al. 2010). More in detail, three selected  
 538 oxysterols (27-Hydroxycholesterol, 7  
 539  $\alpha$ -Hydroxycholesterol and 22R-Hydroxycho-  
 540 lesterol) were tested in 1321N1 cells stably  
 541 expressing GPR17, showing that all the tested  
 542 compounds were able to stimulate GTP $\gamma$ S bind-  
 543 ing, in a concentration-dependent manner, with  
 544 EC<sub>50</sub> values of  $4.99 \pm 0.78$  nM,  $0.70 \pm 0.09$  nM  
 545 and  $0.21 \pm 0.03$  nM, for 27-Hydroxycholesterol,  
 546  $7\alpha$ -Hydroxycholesterol and 22R-Hydroxycho-  
 547 lesterol, respectively.

548 Stimulus of cell membranes with different  
 549 oxysterol concentrations after treatment with  
 550 the purinergic ligand UDP-glucose showed a  
 551 left-shift of the concentration-response curves  
 552 or an enhancement of their maximal [<sup>35</sup>S]  
 553 GTP $\gamma$ S binding stimulation, suggesting that  
 554 these ligands may cooperate under  
 555 neuroinflammatory conditions.

556 In parallel, the effect of different concentra-  
 557 tion of the GPR17 receptor antagonist cangrelor  
 558 on oxysterol-stimulated [<sup>35</sup>S]GTP $\gamma$ S binding was  
 559 evaluated, demonstrating that cangrelor can  
 560 counteract GPR17 activation by oxysterols  
 561 through a competitive mechanism, with IC<sub>50</sub>  
 562 values in a sub-nM range. These results are also  
 563 in agreement with *in silico* data suggesting a  
 564 common orthosteric molecular recognition  
 565 mechanism for oxysterols and other small  
 566 GPR17 ligands, despite different local  
 567 arrangements in the TM binding site (Sensi  
 568 et al. 2014).

569 Among other non-conventional ligands, fur-  
 570 ther evidence showed that SDF-1, historically  
 571 known as the endogenous ligand for CXCR4  
 572 and CXCR7 receptors, is able to transactivate  
 573 GPR17 *in vitro*, specifically increasing the [<sup>35</sup>S]  
 574 GTP $\gamma$ S binding to membrane of GPR17-  
 575 expressing cells, with affinity constant values of  
 576  $0.14 \pm 0.03$  nM. The effect of SDF-1 in  
 577 modulating GPR17 responses *in vitro* was further  
 578 assessed in primary OPC cultures natively  
 579 expressing GPR17. In this model, treatment  
 580 with physiological concentrations of SDF-1 sig-  
 581 nificantly increased the number of cells  
 582 expressing the Myelin Basic Protein MBP com-  
 583 pared to control, thus accelerating OPC differ-  
 584 entiation towards a mature phenotype. The specific

585 involvement of GPR17 in these effects was  
 586 unequivocally demonstrated by further  
 587 experiments showing that, in presence of the  
 588 GPR17 antagonist cangrelor, SDF-1 induced no  
 589 increases of either [<sup>35</sup>S]GTP $\gamma$ S binding to cell  
 590 membranes, or MBP-expression in OPC cultures.  
 591 Moreover, the mechanism by which GPR17 and  
 592 SDF-1 can directly interact to each other has  
 593 been predicted and extensively characterized *in*  
 594 *silico* through molecular modeling (Parravicini  
 595 et al. 2016).

596 These results are in line with literature data,  
 597 that propose a role of SDF-1 in orchestrating  
 598 OPC differentiation and maturation also via  
 599 CXCR4/CXCR7-axis (Li et al. 2012; Patel et al.  
 600 2010; Carbajal et al. 2011).

601 Interestingly, not only GPR17, CXCR4 and  
 602 CXCR7, but also others chemokine receptors,  
 603 like CXCR2, have demonstrated roles in  
 604 regulating OPCs. As previously mentioned (see  
 605 Sect. 2.1), besides sharing the same ligands,  
 606 GPR17 and chemokine receptors are phylogen-  
 607 etically related to each other, and all participate  
 608 to CNS reparative responses. This raises the  
 609 hypothesis that, under neurodegenerative demy-  
 610 elinating conditions, oxysterols and other  
 611 pro-inflammatory ligands, such as SDF-1, act as  
 612 non-conventional molecules with a transversal  
 613 regulatory role, representing a conserved,  
 614 “unspecific” signaling mechanism, by which  
 615 emergency molecules synchronize multiple  
 616 receptors involved in inflammatory/immune  
 617 responses.

### 2.2.3 New GPR17 Synthetic Ligands 628

619  
 620 In 2009 and 2010, two papers reported the devel-  
 621 opment of a new FAC-MS binding method for  
 622 the analysis of GPCRs (Calleri et al. 2010;  
 623 Temporini et al. 2009). In this assay, UDP was  
 624 found to bind to GPR17 with a Kd value of  
 625  $1612.0 \pm 708$  nM that was very similar to the  
 626 Kd value (1140.0 nM) obtained by Ciana et al.  
 627 and Lecca et al. in the [<sup>35</sup>S]GTP $\gamma$ S-binding  
 628 (Ciana et al. 2006; Lecca and Ceruti 2008).  
 629 This paper also unveiled a number of previously  
 630 unreported GPR17 ligands, some of which were  
 631 able to increase [<sup>35</sup>S]GTP $\gamma$ S binding, with  
 632

633 potency values in the  $\mu\text{M}$  and sub-nM range. For  
634 example, the ATP analogue 2-Phenylethynyladenosine-5'-monophosphate Compound N. 4  
635 behaved as a very potent agonist with an  $\text{EC}_{50}$   
636 value of 36 pM. In contrast, other ligands (e.g.: N  
637 <sup>6</sup>-Benzoyl-2'-deoxyadenosine 3',5'-Bis phosphate, referred by the authors as Compound  
638 N. 12) did not induce any increase in [<sup>35</sup>S]  
639 GTP $\gamma$ S binding, but counteracted stimulation  
640 induced by UDP-glucose with an antagonist profile and an affinity constant in the nM range  
641 comparable to that reported for its analogue derivative MRS2179. Both the newly identified  
642 agonists and antagonists displayed similar  
643 behavior in the FAC-MS binding assay (Calleri  
644 et al. 2010). A comparison between these data  
645 and [<sup>35</sup>S]GTP $\gamma$ S binding results have been also  
646 reported in a recent review article on GPR17  
647 (Marucci et al. 2016).

652 In the same year, an advanced *in silico* HM  
653 procedure combined with high-efficiency virtual  
654 screening of more than 120,000 compounds from  
655 the Asinex Platinum Collection (<http://www.asinex.com/>), a lead-like structural library, on  
656 the modeled receptor led to the selection of  
657 5 chemically diverse molecules (the ASINEX  
658 compounds, see Fig. 3 for the chemical structure  
659 of one representative compound,  
660 2-[[5-(2-Methoxyphenyl)-4-(4-methoxyphenyl)-  
661 4H-1,2,4-triazol-3-yl]thio]-N-phenylpropanamide, also referred as ASN 1), that were  
662 completely unrelated to already known ligands.  
663 These compounds were tested *in vitro* in the [<sup>35</sup>S]  
664 GTP $\gamma$ S binding assay, revealing a sub-nM  
665 potency for GPR17 (Eberini et al. 2011) (see  
666 also below). None of these compounds could  
667 have been expected 'a priori' to act on GPR17,  
668 and all of them behaved as much more potent  
669 ligands than GPR17 endogenous activators  
670 (Eberini et al. 2011). Finally, in 2013,  
671 MDL29,951 was reported as an additional small  
672 molecule agonist at GPR17 (Hennen et al. 2013)  
673 (Fig. 3). In a variety of different heterologous  
674 expression systems, MDL29,951-stimulated  
675 GPR17 engaged the entire set of intracellular  
676 adaptor proteins for GPCRs: G proteins of the  
677 G $\alpha_i$ , G $\alpha_s$ , and G $\alpha_q$  subfamily, as well as  
678  $\beta$ -arrestins. This was visualized as alterations in

681 the concentrations of cyclic adenosine  
682 monophosphate and inositol phosphate,  
683 increased  $\text{Ca}^{2+}$  flux, phosphorylation of ERK1/  
684 2, as well as multifaceted cell activation  
685 recorded with label-free dynamic mass redistribution and impedance biosensors.  $\text{pEC}_{50}$  values  
686 for MDL29,951 at GPR17 ranged between 5 and  
687 8.80, depending upon the transfected cell type  
688 and the used read out. MDL29,951-stimulated  
689 GPR17 effects were counteracted in a  
690 concentration-dependent manner by pranlukast  
691 and, to a lesser extent, by montelukast. This is  
692 fully in line with the activities of these  
693 antagonists on recombinant GPR17 in previous  
694 studies, in which pranlukast was significantly  
695 more potent than montelukast in antagonizing  
696 LTD<sub>4</sub>-stimulation of GPR17 (Ciana et al.  
697 2006). In OPCs, MDL29,951 rapidly mobilized  
698 intracellular  $\text{Ca}^{2+}$  in a concentration-dependent  
699 manner and engaged both G $\alpha_i$  and G $\alpha_q$ , but not  
700 G $\alpha_s$  signaling pathways, further suggesting  
701 differences in GPR17 responses between  
702 transfected and native systems (see also  
703 Conclusions). This is at variance from previous  
704 studies reporting G $\alpha_i$  coupling and decreases of  
705 intracellular cAMP as a primary transduction  
706 pathway of GPR17 in OPCs (Daniele et al.  
707 2014; Fumagalli et al. 2011b). However, it has  
708 to be emphasized that, despite being selective for  
709 GPR17 inside the "purine receptor cluster"  
710 (Hennen et al. 2013), MDL29,951 also significantly  
711 interacts with the glycinergic site of the  
712 glutamate NMDA receptor (Salituro et al. 1992).  
713 This may be at the basis of the ability of  
714 MDL29,951 to activate multiple signaling  
715 pathways in both transfected cells and in OPCs,  
716 and of the data reported for this compound on  
717 myelination (see also Sect. 3.1.1).  
718

#### 2.2.4 Agonist-Induced Desensitization and Internalization 729 720

723 In 2011, the first complete agonist-induced  
724 GPR17 desensitization/resensitization study was  
725 published (Daniele et al. 2011). By using [<sup>35</sup>S]  
726 GTP $\gamma$ S binding and cAMP measurements in  
727 1321N1 cells expressing hGPR17, both  
728 UDP-glucose and LTD<sub>4</sub> were shown to induce a  
729 time- and concentration-dependent loss of

730 GPR17 response (homologous desensitization).  
731 GPR17 homologous desensitization was  
732 accompanied by internalization of receptors  
733 inside cells, as assessed by biotin labeling of  
734 cell surface receptors. Desensitization occurred  
735 in a time-dependent manner, with similar kinet-  
736 ics for both agonists. Upon agonist removal,  
737 receptor resensitization occurred with the typical  
738 kinetics of GPCRs. Finally, activation of GPR17  
739 by UDP-glucose induced a partial heterologous  
740 desensitization of LTD<sub>4</sub>-mediated responses (but  
741 not *vice versa*), suggesting that nucleotides have  
742 a hierarchy in producing desensitizing signals.

743 The pattern of GPR17 desensitization and  
744 internalization was fully confirmed and further  
745 expanded in differentiated oligodendroglial  
746 Oli-neu cells that natively express GPR17  
747 (Fratangeli et al. 2013) (Table 1). Agonist-  
748 induced internalization, intracellular trafficking  
749 and membrane recycling of GPR17 were  
750 analyzed by biochemical and immunofluores-  
751 cence assays using an *ad hoc*-developed new  
752 antibody against the extracellular N-terminal of  
753 GPR17. Both UDP-glucose and LTD<sub>4</sub> increased  
754 GPR17 internalization, although with different  
755 efficiency. At early time points, internalized  
756 GPR17 co-localized with transferrin receptor,  
757 whereas at later times it partially co-localized  
758 with the lysosomal marker Lamp1, suggesting  
759 that a portion of GPR17 is targeted to lysosomes  
760 upon ligand binding. Internalization of GPR17  
761 occurred via clathrin-dependent endocytosis  
762 (Fratangeli et al. 2013). Analysis of receptor  
763 recycling and degradation demonstrated that a  
764 significant fraction of GPR17 is recycled to the  
765 cell surface. These results provided the first data  
766 on the agonist-induced trafficking of native  
767 GPR17 in oligodendroglial cells and may have  
768 implications in fine-tuning cell responses to  
769 demyelinating and inflammatory conditions  
770 when these ligands accumulate at lesion sites  
771 (see also Sect. 3.1.2). More recently, GPR17  
772 downregulation by uracil nucleotides and cysLTs  
773 was confirmed in primary cultured OPCs, and the  
774 role of the GRK/ $\beta$ -arrestin machinery in receptor  
775 desensitization and intracellular signaling was  
776 also extensively investigated (Daniele et al.  
777 2014). It was shown that, following OPCs

778 treatment with the two classes of purinergic and 778  
779 cysLT ligands, different GRK isoforms were 779  
780 recruited. Specifically, cysLT-mediated GPR17 780  
781 desensitization mainly involved GRK2 via a G 781  
782 protein-dependent mechanism (Daniele et al. 782  
783 2014). This kinase promoted transient binding 783  
784 of the receptor to  $\beta$ -arrestins, rapid ERK phos- 784  
785 phorylation and sustained nuclear CREB activa- 785  
786 tion. Furthermore, GRK2, whose expression 786  
787 paralleled that of the receptor during the differ- 787  
788 entiation process, was required for cysLT- 788  
789 mediated OPCs maturation (see also Sect. 3.2.). 789  
790 On the other hand, purinergic ligands exclusively 790  
791 recruited GRK5 via a G protein- 791  
792 independent/ $\beta$ -arrestin-dependent mechanism. 792  
793 This kinase induced a stable association between 793  
794 the receptor and  $\beta$ -arrestin, followed by slower 794  
795 and sustained ERK stimulation and marginal 795  
796 CREB activation (Daniele et al. 2014). These 796  
797 results show that, through activation of GPR17 797  
798 and recruitment of specific GRK isoforms, 798  
799 purinergic and cysLT ligands engage distinct 799  
800 intracellular pathways. 800

801 Recently GPR17 desensitization (and its rela- 801  
802 tionship to terminal OPC maturation) has been 802  
803 linked to activation of mTOR (the “mammalian 803  
804 target of rapamycin”), which has long been 804  
805 known to be involved in myelination. During 805  
806 OPC differentiation, mTOR regulates 806  
807 GRK-mediated desensitization of GPR17 by pro- 807  
808 moting the nuclear translocation of the ubiquitin 808  
809 ligase MDM2, which had been previously only 809  
810 involved in cancer via regulation of p53 activity 810  
811 and now emerges as a new interesting actor in 811  
812 oligodendrogenesis (Fumagalli et al. 2015). Spe- 812  
813 cifically, treatment of OPCs with either the 813  
814 mTOR inhibitor rapamycin, or with nutlin-3, a 814  
815 small molecule inhibitor of Mdm2-p53 815  
816 interactions, was shown to keep MDM2 in the 816  
817 cytosol, where it could bind to GRK2 and sustain 817  
818 its degradation, thus impairing the physiological 818  
819 desensitization of GPR17 (Fumagalli et al. 819  
820 2015). Important, prevention of GPR17 desensi- 820  
821 tization was also associated to a defect of OPC 821  
822 maturation, confirming that aberrantly elevated 822  
823 GPR17 levels in late stage OPCs blocks cells at 823  
824 immature stages (Fumagalli et al. 2015). 824

825 In another study, GPR17 plasma membrane  
826 recycling and stability was shown to be also  
827 modulated by SNX27, a recently identified pro-  
828 tein of the endosome-associated retromer com-  
829 plex, whose functions in oligodendrocytes had  
830 never been studied. It was found that, after endo-  
831 cytosis, GPR17 is either sorted into lysosomes  
832 for degradation or recycled to the plasma mem-  
833 brane. Balance between degradation and  
834 recycling was important for modulation of recep-  
835 tor levels at the cell surface, and thus for the  
836 silencing or maintenance of GPR17-signaling  
837 pathways, that, in turn, affect OPC differentia-  
838 tion (see also Sect. 3.2). The endocytic traffick-  
839 ing of GPR17 was mediated by interaction of  
840 SNX27 with a type I PDZ-binding motif located  
841 at the C-terminus of the receptor. Of note,  
842 SNX27 knock-down reduced GPR17 plasma  
843 membrane recycling in differentiating oligoden-  
844 drocytes while accelerating terminal cell matura-  
845 tion. Interestingly, trisomy-linked down-  
846 regulation of SNX27 in the brain of Ts65Dn  
847 mice, a model of Down syndrome, correlated  
848 with a dysfunction in GPR17<sup>+</sup> cells and an  
849 increase in mature oligodendrocytes, which,  
850 however, failed in reaching full maturation,  
851 eventually leading to hypomyelination  
852 (Meraviglia et al. 2016). Thus, disruption of  
853 SNX27/GPR17 interactions leading to  
854 alterations of GPR17 membrane trafficking  
855 might contribute to pathological oligodendrocyte  
856 differentiation and myelination defects present in  
857 Down syndrome (Meraviglia et al. 2016).

### 858 **3 Role of GPR17 in Central** 859 **Nervous System** 860 **Pathophysiology**

#### 861 **3.1 GPR17 Specific Roles** 862 **in Oligodendroglial Functions** 863 **and Myelination**

##### 864 **3.1.1 Physiological Roles** 865

867 In the healthy intact brain, GPR17 expression is  
868 predominantly in oligodendrocyte (OL) cells.  
869 The very first demonstration that, in the adult

brain, GPR17 is highly expressed by a 870  
sub-population of endogenous quiescent paren- 871  
chymal OPCs dates back to 2008 (Lecca et al. 872  
2008) and has sparked a lot of interest on GPR17 873  
role in CNS myelination. Specifically, GPR17 874  
was shown to be present in ramified early neural 875  
cell precursors dispersed throughout brain's gray 876  
and white matter that also positively stained for 877  
typical early OPC markers. Since then, increas- 878  
ing evidence has progressively accumulated to 879  
show a pivotal role of GPR17 in OPC matura- 880  
tion, with different and apparently paradoxical 881  
effects during different phases of the maturation 882  
process (Chen et al. 2009; Fumagalli et al. 883  
2011a) (see also below). 884

*In vitro* studies on purified rat postnatal OPC 885  
cultures showed that GPR17 expression 886  
coincides with a specific temporal window of 887  
the OL differentiation process. It covers two 888  
distinct phases: a first phase, during which early 889  
differentiation markers like NG2, A2B5, PDGF 890  
receptor-alpha and the immature PLP isoform 891  
DM-20 are still present (early stage 2 OPCs in 892  
Fig. 4), and a subsequent phase characterized by 893  
more ramified, still immature 894  
pre-oligodendrocytes (stages 3 and 4 in Fig. 4), 895  
where NG2 has been downregulated and more 896  
advanced markers like O4, O1 and the 897  
proteolipid myelin protein PLP are present 898  
(Fumagalli et al. 2011a). Based on these data, 899  
GPR17 is currently utilized by other independent 900  
scientists to specifically label pre-immature OLs 901  
at these two transition stages (Mitew et al. 2013; 902  
Nakatani et al. 2013; Crociara et al. 2013; Ferrara 903  
et al. 2016). 904

Of note, GPR17 expression progressively 905  
increases during the transition of OPCs to 906  
pre-OLs (when it is maximally expressed in cel- 907  
lular processes), but is then gradually silenced 908  
and never found in fully morphologically mature 909  
OLs (Fumagalli et al. 2011a) (see Fig. 4). 910  
Accordingly, *in vivo*, GPR17 is present in a sub- 911  
set of NG2/Olig2-positive OPCs expressing the 912  
first myelin proteins, but not in more mature cells 913  
expressing myelin basic protein (MBP). Also 914  
during rodent brain development, GPR17 expres- 915  
sion in OPCs precedes myelin production. Inter- 916  
estingly, GPR17 immunoreactivity appears first 917

**Fig. 4 Transient GPR17 expression during oligodendroglial differentiation.** The expression pattern of GPR17 (in red) during oligodendroglial differentiation is shown in parallel to other known oligodendroglial markers (other colours). Progressive differentiation stages are indicated with numbers from 1 to 5. From a functional

point of view, GPR17 exerts opposing stage-specific roles: a positive role for differentiation in early OPCs and a negative function for OL maturation in late OPCs. In late OPCs, gradual silencing of GPR17 is needed to allow OPCs to complete their maturation (see text for more details)

918 in the cell body, partially coinciding with  
 919 markers of the Golgi apparatus, and then gradu-  
 920 ally extends to cellular processes (Boda et al.  
 921 2011). Early after birth, the expression of the  
 922 receptor is low, but progressively expands to  
 923 cover the 80% of OPCs at the end of the third  
 924 week of life. Afterwards, GPR17 is down-  
 925 regulated while myelination proceeds (Boda  
 926 et al. 2011).

927 The transient nature of GPR17 expression in  
 928 OPCs suggests that the receptor may display  
 929 stage-specific roles during OL development.  
 930 Intriguingly, as already reported for the  
 931 Wnt/ $\beta$ -catenin pathway (Fancy et al. 2009; Ye  
 932 et al. 2009) and more recently proposed for the  
 933 transcription factor Olig2 (Mei et al. 2013),  
 934 GPR17 exhibits opposing functions on OL dif-  
 935 ferentiation in relation to its expression stage. In  
 936 cultured cortical postnatal rat OPCs, early recep-  
 937 tor obliteration with small interfering RNAs

profoundly affected their ability to generate 938  
 mature OLs, suggesting that cells are retained at 939  
 a less differentiated stage (Fumagalli et al. 940  
 2011a) (Fig. 4). Although the molecular 941  
 mechanisms at the basis of these events have 942  
 not been yet investigated, these data highlight a 943  
 pivotal role of GPR17 in the initial phases of the 944  
 differentiation process. They support the hypoth- 945  
 esis that, at these stages, GPR17 may be impor- 946  
 tant to keep cells at an immature state which 947  
 may, in turn, be necessary to prepare them for 948  
 myelination (Fumagalli et al. 2011a). In contrast, 949  
 cultured cortical progenitors from GPR17 knock- 950  
 out E15.5 mouse embryos differentiated earlier 951  
 toward mature OLs compared to control cells 952  
 (Chen et al. 2009). The reasons for these 953  
 discrepancies remain unknown, although it may 954  
 be hypothesized that compensatory mechanisms 955  
 are activated as a result of early embryonic 956  
 GPR17 knock out. Of course, the generation of 957

958 conditional transgenic mice in which deletion of  
959 GPR17 in OPCs could be induced under con-  
960 trolled conditions at specific ages will help  
961 clarifying this issue.

962 Lecca and coworkers also clearly showed that  
963 GPR17 is no longer present in morphologically  
964 mature MBP-positive cells (Lecca et al. 2008),  
965 raising for the first time the possibility that loss of  
966 GPR17 at advanced differentiation stages is a  
967 prerequisite to allow cells to complete terminal  
968 maturation. Subsequent *in vivo* data showed that  
969 myelinogenesis is indeed defective in transgenic  
970 mice overexpressing GPR17 under the promoter  
971 of 2',3'-Cyclic-nucleotide 3'-phosphodiesterase  
972 (CNase), a relatively advanced OL marker  
973 (Chen et al. 2009). These animals exhibited  
974 motor disabilities, tremors and precocious death  
975 within the second week of life. The forced and  
976 un-timely expression of GPR17 at a maturation  
977 stage (i.e., in CNase<sup>+</sup> cells), at which GPR17 is  
978 normally already downregulated, might have cre-  
979 ated conflicting signals leading to defective ter-  
980 minal maturation. Thus, interference with the  
981 stage-restricted expression of GPR17 resulting  
982 in un-programmed receptor expression in late  
983 OPCs completely alters the differentiation pro-  
984 gram of these cells. This hypothesis is fully in  
985 line with the demonstration that OPCs  
986 incorporating a vector for GPR17 over-  
987 expression maintained an immature morphologi-  
988 cal phenotype and never expressed the mature  
989 marker CNase, and with data showing that,  
990 under conditions where terminal OPC maturation  
991 is impaired, such as demyelinating diseases (see  
992 Sect. 3.1.2) or treatment with the mTOR inhibi-  
993 tor rapamycin, that reduces OPC maturation,  
994 GPR17 is markedly up-regulated (Fumagalli  
995 et al. 2015; Tyler et al. 2011).

996 Both intrinsic and extrinsic mechanisms could  
997 contribute to GPR17 stage-specific functions  
998 during oligodendrocyte differentiation. GPR17  
999 can be extrinsically regulated by physiological  
1000 ligands accumulating in the extracellular milieu:  
1001 activation of early OPCs (stages 2 and 3 in Fig. 4)  
1002 with GPR17 endogenous putative ligands (i.e.,  
1003 UDP-glucose or LTD<sub>4</sub>) indeed promoted conver-  
1004 sion to more mature cells expressing myelin

1005 markers (Lecca et al. 2008; Fumagalli et al. 1005  
1006 2011a; Ceruti et al. 2011). Consistent with these 1006  
1007 data, GPR17 antagonists like cangrelor (Fig. 3) 1007  
1008 delayed the ability to generate mature cells 1008  
1009 (Lecca et al. 2008; Fumagalli et al. 2011a), 1009  
1010 suggesting that GPR17 endogenous ligands are 1010  
1011 basally released in culture and are responsible for 1011  
1012 the observed spontaneous OPC *in vitro* matura- 1012  
1013 tion. In another independent study, while not 1013  
1014 modifying the potential of adult multipotent neu- 1014  
1015 ral stem cells, montelukast, which also acts as a 1015  
1016 GPR17 antagonist (Ciana et al. 2006; Benned- 1016  
1017 Jensen and Rosenkilde 2010; Lecca et al. 2008), 1017  
1018 markedly increased their proliferation rate, 1018  
1019 suggesting that GPR17 antagonism induces 1019  
1020 retention of cells at a more undifferentiated 1020  
1021 stage (Huber et al. 2011). 1021

1022 As already mentioned, besides cAMP inhibi- 1022  
1023 tion, GPR17 has been also shown to specifically 1023  
1024 mediate activation of delayed rectifier K<sup>+</sup> 1024  
1025 currents (Table 1) in a sub-population of OPCs 1025  
1026 and O4<sup>+</sup> pre-OLs, but not in mature OLs. This 1026  
1027 effect was shown to contribute to the terminal 1027  
1028 maturation of OPCs and to their migratory 1028  
1029 abilities. 1029

1030 In contrast with the above studies, 1030  
1031 MDL29,951, the new putative GPR17 agonist 1031  
1032 mentioned above, was reported to inhibit, rather 1032  
1033 than stimulate, OL maturation (Hennen et al. 1033  
1034 2013). However, it is worth to note that, due to 1034  
1035 the *transient* expression of GPR17 in culture, the 1035  
1036 timing of OPC manipulation and treatment is 1036  
1037 crucial for obtaining comparable results. On the 1037  
1038 other hand, as already mentioned, MDL29,951 is 1038  
1039 not a selective ligand for this receptor, and inde- 1039  
1040 pendent effects could be due to its antagonistic 1040  
1041 activity at the glycinergic site of the glutamate 1041  
1042 NMDA receptor (Salituro et al. 1992), which has 1042  
1043 been indeed reported to promote OPC differenti- 1043  
1044 ation (Li et al. 2013). 1044

1045 Globally, these findings suggest that GPR17 1045  
1046 exerts opposing stage-specific roles: a positive 1046  
1047 role for differentiation in early OPCs and a nega- 1047  
1048 tive function for OL maturation in late OPCs. 1048  
1049 They also suggest that, in late OPCs, physiologi- 1049  
1050 cal GPR17 silencing is needed to allow cells to 1050  
1051 complete their maturation program. The latter 1051

1052 may occur via either GPR17 desensitization/  
 1053 internalization by endogenous agonists or by  
 1054 GPR17-mediated engagement of intracellular  
 1055 pathways culminating in nuclear events, or  
 1056 both. Blockade of GPR17 mRNA translation  
 1057 into the receptor protein a specific microRNA  
 1058 has been also recently reported to contribute to  
 1059 GPR17 regulation during OPC maturation  
 1060 (Lecca et al. 2016).

### 1063 3.1.2 Dysregulation in Demyelinating 1062 Neurodegenerative Diseases

1065 The demonstration that levels of endogenous  
 1066 nucleotides and cysLTs are massively increased  
 1067 upon CNS trauma and ischemia and their  
 1068 hypothesized roles as danger signals after injury  
 1069 (Davalos et al. 2005; Haynes et al. 2006) has  
 1070 raised the hypothesis that GPR17 may act as a  
 1071 crucial mediator of reactivity to acute injury.  
 1072 While physiologically GPR17 is mostly an  
 1073 oligodendroglial receptor, after acute injury,  
 1074 GPR17 is sequentially induced in dying neurons  
 1075 inside and at the borders of the ischemic/trau-  
 1076 matic lesion, in infiltrating microglia/  
 1077 macrophages and in activated parenchymal  
 1078 OPCs in the lesion's surrounding areas, with  
 1079 similar expression patterns in different models  
 1080 of pathology. In more detail, in both rats and  
 1081 mice, 24 h after permanent middle cerebral artery  
 1082 occlusion (MCAo), GPR17 is up-regulated in  
 1083 neurons damaged by the ischemic insult inside  
 1084 the ischemic core (Ciana et al. 2006; Lecca et al.  
 1085 2008). When the penumbra area is well visible  
 1086 and most of the neurons in the core are dead,  
 1087 GPR17 appears on highly activated microglia  
 1088 and blood-borne macrophages at the borders of  
 1089 the lesion (Lecca et al. 2008). This has been  
 1090 independently confirmed to also occur in a tran-  
 1091 sient MCAo rodent model, where the number of  
 1092 GPR17 expressing cells was significantly  
 1093 upregulated in two distinct phases, 24 h and  
 1094 7 days after reperfusion, consistent with an  
 1095 early acute neuronal injury followed by a late  
 1096 microgliosis (Zhao et al. 2012). It is known that  
 1097 OPCs are extremely sensitive to the pathophysi-  
 1098 ological state of the brain, and that they react to  
 1099 many different types of experimentally induced  
 1100 insults. Starting from 72 h after the insult, in the

regions surrounding the ischemic area and in the 1101  
 ipsilateral corpus striatum of MCAo mice, a 1102  
 higher number of GPR17-expressing OPCs was 1103  
 indeed found compared to contralateral hemi- 1104  
 sphere (Lecca et al. 2008), suggesting an 1105  
 increased proliferation rate in response to 1106  
 demyelination. 1107

Dysregulated expression of GPR17 has been 1108  
 described also after traumatic injury, in both 1109  
 brain (Boda et al. 2011) and spinal cord (Ceruti 1110  
 et al. 2009). In stab wound, a model of cortical 1111  
 trauma, early after lesion, the density of GPR17- 1112  
 expressing OPCs in gray matter was reduced 1113  
 compared to contralateral cortex, consistent 1114  
 with a global oligodendroglial loss. At later 1115  
 times, GPR17<sup>+</sup> cells increased significantly in 1116  
 number around the lesion in both gray and 1117  
 white matter, likely due to the expansion of the 1118  
 NG2 cell pool, which, in turn, reflects an attempt 1119  
 to replace dead OPCs. This reactivity lasted up to 1120  
 7 days and then declined over time, going back to 1121  
 basal levels at 14 days after lesion. This pattern 1122  
 has been confirmed in human samples from 1123  
 patients with traumatic brain injury (Franke 1124  
 et al. 2013). In both neurosurgical and autopsy 1125  
 specimens, GPR17 expression was evident inside 1126  
 the contused core and progressively declined 1127  
 distally according to a spatio-temporal gradient. 1128  
 Inside and around the core, GPR17 labeled dying 1129  
 neurons, reactive astrocytes, and activated 1130  
 microglia/macrophages. In peri-contused paren- 1131  
 chyma, GPR17 was found on OPCs, some of 1132  
 which had proliferated, indicating 1133  
 re-myelination attempts. In agreement with the 1134  
 above data, in a double transgenic model of 1135  
 Alzheimer's disease (the APPS1 mouse) a 1136  
 high number of GPR17-positive cells 1137  
 accumulated close to amyloid plaques in gray 1138  
 matter, revealing receptor up-regulation as a fea- 1139  
 ture of oligodendroglial reactivity also in this 1140  
 pathological condition (Boda et al. 2011). 1141

Similar GPR17 changes have been reported 1142  
 also in typically de-myelinating diseases such as 1143  
 in models of multiple sclerosis (MS). In this 1144  
 disease, remyelination occurs after the initial 1145  
 myelin damage, but it fails after multiple demye- 1146  
 lination episodes, which eventually leads to axo- 1147  
 nal degeneration and progressive disability 1148

1149 (Franklin and Ffrench-Constant 2008). Interest-  
 1150 ingly, synthesis of cysLTs is increased in MS  
 1151 plaques and in the spinal cord of mice subjected  
 1152 to experimental autoimmune encephalomyelitis  
 1153 (EAE), an immune-mediated model of demyelin-  
 1154 ation (Whitney et al. 2001). Of note,  
 1155 montelukast, an antagonist at both CysLT1 and  
 1156 GPR17, attenuated CNS infiltration of inflamma-  
 1157 tory cells and the clinical symptoms of EAE  
 1158 (Wang et al. 2011). However, the exact contribu-  
 1159 tion of GPR17 to these effects has not been  
 1160 investigated in detail. Overexpression of the  
 1161 GPR17 transcript has been observed in both  
 1162 EAE mice and in a cohort of human MS tissues  
 1163 (Chen et al. 2009). GPR17 expression was sig-  
 1164 nificantly increased in MS plaques as compared  
 1165 with white matter from non-neurological donor  
 1166 samples and normal-appearing white matter from  
 1167 MS donors. In a similar way, acute damage to  
 1168 myelin induced by lysolecithin (Lys) injection in  
 1169 corpus callosum induced a strong overexpression  
 1170 of GPR17 at the lesion site 10 days after injury  
 1171 (Boda et al. 2011). Thus, independently of the  
 1172 original cause, GPR17 is abnormally  
 1173 up-regulated in MS and some models of neuro-  
 1174 degenerative conditions characterized by myelin  
 1175 disruption (Fumagalli et al. 2016).

1176 On this basis, it could be hypothesized that,  
 1177 after damage, GPR17 is initially induced to pro-  
 1178 mote the growth and differentiation of OPCs;  
 1179 however, at later stages, due to lack of appropri-  
 1180 ate environmental stimuli, presence of inflamma-  
 1181 tory signals and/or intrinsic factors,  
 1182 physiological GPR17 downregulation is  
 1183 impeded, thus freezing cells at a stand-by stage,  
 1184 where they are neither proliferating nor  
 1185 differentiating. When this happens, interventions  
 1186 targeting GPR17 may help bypassing this check-  
 1187 point and facilitate terminal maturation. Since  
 1188 GPR17 is a *membrane* receptor that, at variance  
 1189 from other intrinsic regulators of oligoden-  
 1190 drogenesis, can be easily targeted and  
 1191 manipulated with pharmacological agents, it is  
 1192 envisaged that agents counteracting GPR17 aber-  
 1193 rant expression under these conditions could  
 1194 induce OPCs to resume myelination and promote  
 1195 neurorepair. To support this hypothesis, in  
 1196 MCAo animals, administration of GPR17

1197 antagonists such as cangrelor or montelukast 1197  
 (Ciana et al. 2006; Lecca et al. 2008), or 1198  
 GPR17 silencing due to *in vivo* delivery of spe- 1199  
 cific antisense oligonucleotides (Ciana et al. 1200  
 2006; Lecca et al. 2008) or small interfering 1201  
 RNAs (Zhao et al. 2012) resulted in a significant 1202  
 reduction in brain's ischemic volume. Use of 1203  
 GPR17 anti-sense oligonucleotides also reduced 1204  
 damage and improved functional recovery in a 1205  
 model of spinal cord injury, in line with the 1206  
 hypothesis that GPR17 is aberrantly 1207  
 overexpressed as a consequence of damage 1208  
 (Ceruti et al. 2009). 1209

1210 In contrast to what observed in MCAo, in a rat 1210  
*neonatal* model of ischemic periventricular 1211  
 leukomalacia (PVL), a common cerebral white 1212  
 matter injury, the GPR17 agonist UDP-glucose 1213  
 (and not an antagonist) significantly contributed 1214  
 to myelin sheaths recovery and improved motor 1215  
 functions, learning and coordination in PVL pups 1216  
 (Mao et al. 2012). The reason for this discrep- 1217  
 ancy may reside in the different outcome of the 1218  
 ischemic insult in neonatal brain compared to 1219  
 adults. It could be hypothesized that, in neonatal 1220  
 pups, existing OPCs, which are very sensitive to 1221  
 ischemic death, are immediately killed by the 1222  
 ischemic insult, with no obvious GPR17 1223  
 upregulation; conversely, being these cells 1224  
 generated at distinct waves during the first 1225  
 weeks of life at much higher rates compared to 1226  
 adulthood, a GPR17 agonist (instead of an antag- 1227  
 onist) would allow to properly activate newborn 1228  
 OPCs, thus favouring the formation of myelin 1229  
 sheaths and neurological recovery. 1230

1231 Several of the still obscure aspects of GPR17 1231  
 pathophysiology have been linked to the diffi- 1232  
 culty of establishing a causal relationship 1233  
 between GPR17 expression and myelination 1234  
*in vivo*. Since GPR17 is no longer expressed in 1235  
 mature myelinating OLs (Lecca et al. 2008; 1236  
 Fumagalli et al. 2015), it was impossible to dem- 1237  
 onstrate that cells that have expressed GPR17 in 1238  
 their earlier life can indeed myelinate. Only 1239  
 recently, the generation of the first 1240  
 GPR17<sup>iCreER</sup><sup>T2</sup>-GFP reporter mouse line for 1241  
 fate mapping studies has allowed to follow the 1242  
 final destiny of GPR17<sup>+</sup> cells during both physi- 1243  
 ological differentiation and in disease, thanks to 1244

1245 the inducible expression of the green fluores-  
 1246 cence protein (GFP). In these mice, upon tamox-  
 1247 ifen induced recombination, OPCs expressing  
 1248 GPR17 at that very specific moment, become  
 1249 green and can be traced as such for the entire  
 1250 animal's life. Use of these mice has allowed to  
 1251 show that, in normal brain, GFP<sup>+</sup> cells differenti-  
 1252 ate very slowly (needing about 3 months to reach  
 1253 maturity), but after acute insults, they rapidly  
 1254 reacted to damage with proliferation and migra-  
 1255 tion toward the injured site, thus representing a  
 1256 'reserve pool' of adult quiescent progenitors  
 1257 maintained for repair purposes (Vigano et al.  
 1258 2016). A full characterization of the long-term  
 1259 events occurring in the brain of ischemic MCAo  
 1260 GPR17iCreER<sup>T2</sup>-GFP mice has shown that,  
 1261 despite massive recruitment of GFP<sup>+</sup> green  
 1262 OPCs at the ischemic site, only a few percentage  
 1263 of these cells become mature myelinating OLs,  
 1264 likely due to local unfavourable inflammatory  
 1265 milieu (Vigano et al. 2016; Bonfanti et al. 2017).  
 1266 More recently, it has been demonstrated that  
 1267 GPR17 over-activation inhibited oligodendro-  
 1268 cyte survival by reducing intracellular cAMP  
 1269 levels and inducing expression of the  
 1270 pro-apoptotic gene *Xaf1*. GPR17 overactivation  
 1271 also negatively regulated protein kinase A sig-  
 1272 naling pathway and expression of the transcrip-  
 1273 tion factor c-Fos. In line with these data, in the  
 1274 lysolecithin-mediated demyelination injury  
 1275 model, the pharmacological inhibition of  
 1276 GPR17 with pranlukast increased oligodendro-  
 1277 cyte survival and promoted immature oligoden-  
 1278 drocyte differentiation through the upregulation  
 1279 of Epac1, the exchange factor directly activated  
 1280 by cAMP (Ou et al. 2016). These data are fully  
 1281 consistent with our results in other injury models  
 1282 characterized by demyelination and abnormal  
 1283 GPR17 upregulation (summarized in Fumagalli  
 1284 et al. 2016), suggesting that under these  
 1285 conditions GPR17 inhibition has potential for  
 1286 treatment of demyelinating diseases (Ou et al.  
 1287 2016).

### 3.2 GPR17 in Brain Rejuvenation

1288

A recent report has investigated the roles of  
 GPR17 in age-associated cognitive decline  
 (Marschallinger et al. 2015). Authors have first  
 shown that oral administration of montelukast  
 (an antagonist of both CysLTR1 and GPR17,  
 see above), for 6 weeks to moderately old rats  
 (20 months old) resulted in structural and func-  
 tional rejuvenation of aged brains, as  
 demonstrated by restoration of blood brain bar-  
 rier integrity, reduced microglia activation in the  
 brain, increased levels of hippocampal  
 neurogenesis and significantly improved learning  
 and memory tasks. Important, montelukast had  
 no effects on the behaviour and cognitive  
 abilities of young animals, suggesting that its  
 actions specifically target an aging associated  
 defect (see also below). Regression and correla-  
 tion analyses showed that montelukast-induced  
 learning improvement in the old animals was  
 independent of the changes in microglia mor-  
 phology but rather depended on the rate of  
 neurogenesis measured as increased number of  
 proliferating neuroblasts in hippocampal dentate  
 gyrus. Interestingly, authors also provided immu-  
 nohistochemical evidence for the presence of  
 GPR17, but not CysLTR1, in a subset of  
 doublecortin (DCX)<sup>+</sup> newborn neurons in hippo-  
 campal dentate gyrus, suggesting a role in the  
 proliferation and specification of these cells.  
 Studies on neurospheres obtained from mice  
 lacking FOXO1, a GPR17 regulating transcrip-  
 tion factor, and from GPR17<sup>-/-</sup> mice indeed  
 confirmed montelukast effects be due to action  
 on GPR17/DCX<sup>+</sup> neuroblasts in hippocampal  
 dentate gyrus, leading to increased neurogenesis.  
 Globally these data suggest that, under normal  
 conditions, GPR17 exerts a negative control on  
 the proliferation of neural progenitors in the hip-  
 pocampus; in aged animals, due to the overall  
 decrease of neurogenesis, GPR17 inhibition of  
 proliferation becomes detrimental and  
 contributes to memory impairment. Under such  
 pathological conditions, montelukast can restore  
 neurogenesis by alleviating GPR17 inhibitory  
 effect (Marschallinger et al. 2015).

### 1334 3.3 GPR17 in Gliomas

1335 OL markers such as Olig2, PDGFR $\alpha$  and NG2  
 1336 are often expressed in glioma cells. Little is  
 1337 known about the origin of these tumors, but it is  
 1338 possible that they arise from dysregulated OPCs  
 1339 (Liu et al. 2011b). Considering that OPCs are the  
 1340 only proliferating population in the adult brain,  
 1341 defects in differentiation mechanisms favouring  
 1342 cell proliferation could be a primary cause of  
 1343 gliomas. A complementary strategy for tumor  
 1344 treatment is to promote pathways for maintaining  
 1345 quiescence and/or driving terminal differentia-  
 1346 tion of the tumoral progenitors. In this respect,  
 1347 a recent microarray analysis of mouse and human  
 1348 gliomas aimed at unveiling new candidates pro-  
 1349 moting differentiation or quiescence has  
 1350 highlighted GPR17 as a new potential target  
 1351 (Dougherty et al. 2012). In glioma cells, treat-  
 1352 ment with UDP, UDP-glucose or LTD<sub>4</sub> indeed  
 1353 reduced the formation of glioma spheres  
 1354 suggesting that GPR17 stimulation can represent  
 1355 a good strategy to drive the differentiation of  
 1356 highly proliferative uncommitted tumor cells to  
 1357 the oligodendroglial fate, negatively affecting  
 1358 both tumor cell proliferation and self-renewal  
 1359 (Dougherty et al. 2012). These data are in line  
 1360 with the fact that most of the OPCs expressing  
 1361 GPR17 in brain are quiescent (Lecca et al. 2008),  
 1362 and support the pro-differentiative effects of its  
 1363 putative endogenous ligands (see also Sects. 2.1  
 1364 and 3.2).

---

### 1365 4 Conclusions

1366 GPR17 has emerged as a new GPCR of great  
 1367 interest for drug development. It is almost exclu-  
 1368 sive localization to OPCs, the myelin forming  
 1369 cells and the only (slowly) proliferating cell pop-  
 1370 ulation in the intact brain, has highlighted  
 1371 GPR17 as a novel pharmacological target for  
 1372 demyelinating diseases. At variance from other  
 1373 myelinating genes, GPR17 is a membrane recep-  
 1374 tor, thus amenable for pharmacological modula-  
 1375 tion, which has attracted a lot of interest for the  
 1376 development of new therapeutic approaches to

MS and other neurodegenerative diseases 1377  
 characterized by myelin disruption. The recent 1378  
 demonstration that GPR17 is also expressed by a 1379  
 subset of hippocampal neural progenitors 1380  
 involved in cognitive functions does not detract 1381  
 from the potential interest of GPR17 ligands in 1382  
 neurodegenerative diseases, since, as 1383  
 demonstrated by the montelukast study 1384  
 (Marschallinger et al. 2015), these ligands may 1385  
 be active only when specific pathological GPR17 1386  
 changes are present. 1387

The recent studies on GPR17 revealed its 1388  
 transient expression in OPCs and a more com- 1389  
 plex role than expected: a pro-differentiating role 1390  
 in early OPCs and a negative function on matu- 1391  
 ration in late stage OPCs. Thus, the apparently 1392  
 contrasting *in vitro* data obtained with different 1393  
 GPR17 stimulatory agents (Lecca et al. 2008; 1394  
 Fumagalli et al. 2011a; Hennen et al. 2013) 1395  
 may depend on the specific differentiation stage 1396  
 at which these compounds have been added to 1397  
 cultured OPCs. It may well be that the function 1398  
 of GPR17 is different in the intact and diseased 1399  
 brain, based on the availability of its endogenous 1400  
 ligands. If uracil nucleotides, cysLTs, oxysterols 1401  
 and chemokines like SDF-1 are indeed among 1402  
 the signaling molecules able to activate GPR17 1403  
*in vivo* (see also below), we envisage that their 1404  
 role would be more likely unveiled under patho- 1405  
 logical conditions, where these ligands massively 1406  
 accumulate at lesion sites inside the CNS. 1407

Experiments in a wide variety of rodent 1408  
 models of neurodegeneration have shown that, 1409  
 independently of the nature of the insult (ischemic, 1410  
 traumatic or toxic) and of the presence of 1411  
 any concomitant neuronal pathology, demyelinating 1412  
 conditions invariably led to GPR17 1413  
 upregulation. We believe that this dysregulation 1414  
 reflects an initial attempt to repair the lesion by 1415  
 stimulating OPCs differentiation via GPR17, but 1416  
 that this attempt is later invalidated by the inabil- 1417  
 ity of maturing cells to downregulate/internalize 1418  
 the receptor, which, in turn, leads a differentia- 1419  
 tion blockade. On this basis, it is envisaged that 1420  
*GPR17 antagonists* would be useful in MS and 1421  
 neurodegenerative diseases. By counteracting 1422  
 GPR17 aberrant dysfunction, antagonists would 1423  
 help OPCs to complete their maturation, thus 1424

1425 re-establishing endogenous remyelination, as  
1426 recently also confirmed (Ou et al. 2016).

1427 Due to the still ambiguous state of the phar-  
1428 macology for this receptor, the Nomenclature  
1429 Committee of the International Union of Phar-  
1430 macology (NC-IUPHAR) has not yet officially  
1431 de-orphanized this GPCR (Davenport et al.  
1432 2013). However, as also emphasized by  
1433 NC-IUPHAR, much of the work in this area has  
1434 been based on recombinant expression systems  
1435 using different host cells and transfection  
1436 methodologies compared to data derived from  
1437 native cells. In recombinant “artificial” cell  
1438 systems, activity tests are highly dependent on  
1439 the experimental conditions utilized and subject  
1440 to several artifacts, especially in the case of  
1441 receptors’ constitutive activation, a typical fea-  
1442 ture of several GPCRs including GPR17  
1443 (Bened-Jensen and Rosenkilde 2010; Maekawa  
1444 et al. 2009; Qi et al. 2013; Eggerickx et al. 1995;  
1445 Uhlenbrock et al. 2002; Rosenkilde et al. 2006;  
1446 Qin et al. 2011; Im 2004) that can profoundly  
1447 alter ligand behavior (Kenakin 2001; Davenport  
1448 et al. 2013).

1449 In terms of drug development, neither uracil  
1450 nucleotides nor CysLTs are suitable to this pur-  
1451 pose, because neither ligand class is competent to  
1452 discriminate between the functions of purinergic  
1453 receptors, CysLT receptors, and GPR17 *in vivo*,  
1454 where multiple receptors are often co-expressed.  
1455 Nevertheless, the already available *in vivo* rodent  
1456 data reporting positive neuro-reparative effects  
1457 induced by commercially available montelukast  
1458 or pranlukast (Yu et al. 2005a, b), which are  
1459 potent (although non selective) GPR17  
1460 antagonists, foster the search for further GPR17  
1461 ligands (Eberini et al. 2011; Hennen et al. 2013)  
1462 and may represent an important advancement for  
1463 patients with neurodegenerative diseases.

Hsieh J, Bassel-Duby R, Olson EN, Lu QR (2009)  
HDAC1 and HDAC2 regulate oligodendrocyte differ-  
entiation by disrupting the beta-catenin-TCF interac-  
tion. *Nat Neurosci* 12(7):829–838
- Yu GL, Wei EQ, Wang ML, Zhang WP, Zhang SH, Weng  
JQ, Chu LS, Fang SH, Zhou Y, Chen Z, Zhang Q,  
Zhang LH (2005a) Pranlukast, a cysteinyl leukotriene  
receptor-1 antagonist, protects against chronic ische-  
mic brain injury and inhibits the glial scar formation in  
mice. *Brain Res* 1053(1–2):116–125
- Yu GL, Wei EQ, Zhang SH, Xu HM, Chu LS, Zhang WP,  
Zhang Q, Chen Z, Mei RH, Zhao MH (2005b)  
Montelukast, a cysteinyl leukotriene receptor-1 antag-  
onist, dose- and time-dependently protects against  
focal cerebral ischemia in mice. *Pharmacology* 73  
(1):31–40
- Zhang K, Zhang J, Gao ZG, Zhang D, Zhu L, Han GW,  
Moss SM, Paoletta S, Kiselev E, Lu W, Fenalti G,  
Zhang W, Muller CE, Yang H, Jiang H, Cherezov V,  
Katritch V, Jacobson KA, Stevens RC, Wu B, Zhao Q  
(2014) Structure of the human P2Y12 receptor in  
complex with an antithrombotic drug. *Nature* 509  
(7498):115–118
- Zhang D, Gao ZG, Zhang K, Kiselev E, Crane S, Wang J,  
Paoletta S, Yi C, Ma L, Zhang W, Han GW, Liu H,  
Cherezov V, Katritch V, Jiang H, Stevens RC,  
Jacobson KA, Zhao Q, Wu B (2015) Two disparate  
ligand-binding sites in the human P2Y1 receptor.  
*Nature* 520(7547):317–321
- Zhao B, Zhao CZ, Zhang XY, Huang XQ, Shi WZ, Fang  
SH, Lu YB, Zhang WP, Xia Q, Wei EQ (2012) The  
new P2Y-like receptor G protein-coupled receptor  
17 mediates acute neuronal injury and late  
microgliosis after focal cerebral ischemia in rats. *Neuro-  
science* 202:42–57
