Samy Elias, Ph.D., Associate Dean for the Engineering Research Center

# 1 INTRODUCTION

## 1.1 Background

The Coordinated Federal Lands Highways Technology Improvement Program (CTIP) was developed with the purpose of serving the immediate needs of those who design and construct Federal Lands Highways, including Indian Reservation roads, National Park roads and parkways, and forest highways. A wide assortment of guardrails, bridge rails and transitions are being used on roads under the jurisdiction of the National Park Service and other Federal agencies. These guardrails, bridge rails and transitions are intended to blend in with the roadside in order to preserve the visual integrity of the parks and parkways. However, many of them have never been crash tested (1,2). A testing program was developed in order to ensure that the safety hardware used in these areas are safe for the traveling public. The Steel Backed Log Rail was included in the second Federal Highway Administration (FHWA) testing program - Guardrail Testing Program II.

## 1.2 Test Installation

The Steel-Backed Log Rail was constructed from 10-in. diameter logs backed by 6-in. x  $\frac{3}{8}$ -in. x 9-ft 9-in. ASTM A588 steel plates. Backup plates were attached to the log rails with  $\frac{3}{8}$ -in. x 4-in. lag screws and the 10 ft long rail elements were connected with 6 in. x  $\frac{3}{8}$  in. x 2-ft. 6-in. ASTM A588 steel splice plates. The railing was mounted on 12 in. diameter round posts with cast steel blockouts placed at each splice joint. The center of the rail elements was placed at a height of 1 ft - 9 in.

Both the posts and rail elements of this 80 ft long system consisted of ponderosa pine. All fastener hardware was manufactured from steel conforming to ASTM A588. Photographs of the Steel-Backed Log Rail are shown in Figures 1 and 2. Design details are shown in Figures 3 and 4.

## 2 TEST CONDITIONS

### 2.1 Test Vehicles

A 1984 Dodge Colt, shown in Figure 5, was used as a test vehicle in Test SBLR-1. As shown in Figure 6, the vehicle had a test inertial and a gross static weight of 1850 lbs and 2015 lbs, respectively.

A 1986 3/4 ton Chevrolet pickup, shown in Figure 7, was used as a test vehicle in Test SBLR-2. This vehicle had test inertial and gross static weights of 5400 lbs and 5565 lbs, respectively. Vehicle weights and dimensions are shown in Figure 8.

Center of gravity heights for both vehicles were determined using the suspension method (3). This method is based on the principle that the center of gravity of any freely suspended body is in the vertical plane through the point of suspension. Each vehicle was suspended in three positions, and the respective planes containing the center of gravity were established. The intersection of these planes pinpointed the location of the center of gravity. The longitudinal location of the center of gravity was confirmed by using the axle weights of the vehicles.

Black and white-checked targets were placed on the vehicle for high-speed film analysis. Two targets were located on the center of gravity, one on the top and one on the driver's side of the test vehicle. Additional targets, visible from all three high speed cameras, were located for reference. The front wheels of the test vehicle were aligned for camber, caster, and toe-in values of zero so that the vehicle would track properly along the guide cable. Two 5B flash bulbs, fired by a pressure tape switch on the front bumper, were mounted on the roof of each vehicle to establish the time of impact on the high-speed film.

## 2.2 Data Acquisition Systems

### 2.2.1 Accelerometers

Two triaxial piezoresistive accelerometer systems with a range of  $\pm 200$  g's (Endevco Model 7264) were used to measure vehicle accelerations. The accelerometers were rigidly attached to a metal block mounted near the vehicle's center of gravity. Accelerometer signals were received and conditioned by an onboard Series 300 Multiplexed FM Data System built by Metraplex Corporation. The multiplexed signal was then transmitted to a Honeywell 101 Analog Tape Recorder. "Computerscope" computer software was used to digitize accelerometer data and transfer it to a Cyclone 386/16 Mhz computer with a high-speed data acquisition board. "DSP" computer software was then used to analyze and plot the data on a PC Brand 486/33 Mhz computer.

### 2.2.2 High Speed Photography

Four high-speed 16-mm cameras, with operating speeds of approximately 500 frames/sec were used to film the crash tests. A Red Lake Locam with a 12.5 mm lens was placed above the test installation to provide a field of view perpendicular to the ground. A Photec IV, with an 80-mm lens, was placed downstream from the impact point and had a field of view parallel to the barrier. A second Photec IV, with a 55-mm lens, was placed on the traffic side of the bridge rail and had a field of view perpendicular to the barrier. Another Red Lake Locam with a 5.7-mm lens was placed onboard the vehicle to record dummy motions during the test. A schematic of the camera locations for each test is shown in Figure 9. A white-colored backboard with a 2-ft by 2-ft grid was placed behind the rail in view of the overhead camera. This backboard provided a visible reference system to use in the analysis of the overhead high-speed film. The film was analyzed using a Vanguard Motion Analyzer.

### 2.2.3 Speed Trap

Eight tape pressure switches spaced at 5-ft intervals were used to determine the speed of the vehicle before and after impact. Each tape switch fired a strobe light and sent an electronic timing mark to the data acquisition system as the left front tire of the test vehicle passed over it. Test vehicle speeds were determined from electronic timing mark data recorded on the analog tape. Strobe lights and high speed film analysis are used only as a backup in the event that vehicle speeds cannot be determined from the electronic data.

FIGURE 9. Layout of High-Speed Cameras

### 3 TEST RESULTS

#### 3.1 Test SBLR-1 (1850 lbs, 50.6 mph, 19.2 deg)

The 1984 Dodge Colt was directed into the Steel-Backed Log Rail using a reverse tow and cable guidance system (4). The vehicle was released from the tow cable and guidance system and was free wheeling at impact. The speed of the vehicle at impact was 50.6 mph and the angle of impact was 19.2 degrees. The impact point, shown in Figure 10, was located midspan between Post Nos. 2 and 3, or 15 ft from the upstream end of the installation. A summary of the test results and sequential photographs is shown in Figure 11. Additional sequential photographs are shown in Figures 12 through 14.

Upon impact with the log rail, the front bumper slipped under the rail, and the front right corner of the vehicle began to crush inward. The vehicle slid along the log rail and reached Post No. 3 approximately 64 ms after impact. 216 ms after impact the vehicle reached Post No. 4 and became parallel to the rail at approximately 352 ms. The vehicle exited the rail at an angle of 2 degrees approximately 503 ms after impact. After exiting the rail, the vehicle continued to travel downstream and to the left, coming to a rest 240 ft downstream from impact and 153 ft to the left of a line parallel to the railing face. This vehicle trajectory is shown in Figure 15.

Test vehicle damage was relatively minor and was largely limited to the right-front quarter panel and passenger door, as shown in Figure 16. There was no intrusion or deformation of the occupant compartment. Vehicle crush measurements are shown in Figure 17.

Damage to the Log Rail consisted of minor scrapes on the surface of the rail and a maximum permanent deflection of  $2 \frac{1}{16}$  in. at the first post after impact. This damage can be seen in Figure 18. The effective coefficient of friction was found to be 1.02 and would be classified as "marginal" according to the AASHTO Guide Specifications for Bridge Railings (5).

The longitudinal and lateral occupant impact velocities as determined from accelerometer data were 24.3 fps and 21.1 fps, respectively. The highest 10-ms average occupant ridedown decelerations were 3.9 g's (longitudinal) and 4.8 g's (lateral). Accelerometer traces from Test SBLR-1 are shown in Appendix A.

### 3.2 Test SBLR-2 (5400 lbs, 46.1 mph, 20.9 deg)

A 1986 3/4 ton Chevrolet Pickup was directed into the steel-backed log rail using a reverse tow and cable guidance system (4). The vehicle was released from the tow cable and guidance system and was free wheeling at impact. The speed of the vehicle at impact was 46.1 mph and the angle of impact was 20.9 degrees. The impact point, shown in Figure 19, was located midspan between Post Nos. 2 and 3, or 15 ft from the upstream end of the rail. A summary of the test results and sequential photographs is shown in Figure 20. Additional sequential photographs are shown in Figures 21 and 22.

Upon impact, the bumper of the test vehicle began to ride up onto the log rail. The vehicle traveled along the top of the log rail until it reached Post No. 5 approximately 448 ms after impact. After impacting Post No. 5, the vehicle began to rotate clockwise, coming to rest perpendicular to the rail, 45 ft downstream from impact. The vehicle trajectory is shown in Figure 23.

Test vehicle damage, shown in Figure 24, was limited to the undercarriage on the right-front corner and along the right side. Vehicle crush measurements are shown in Figure 25. The vehicle remained upright both during and after the test, and there was no intrusion of the occupant compartment.

Damage to the log rail consisted of scrapes and gouges along the traffic face and at some of the posts. A maximum permanent deflection of  $9 \frac{1}{8}$  in. was measured at Post No. 3. The damaged barrier is shown in Figure 26.

As a result of technical problems incurred during this test, the accelerometer data was not available. Therefore, the high speed film was analyzed to obtain longitudinal and lateral occupant impact velocities of 14.8 fps and 12.8 fps, respectively. The highest occupant

ridedown decelerations in the longitudinal and lateral directions were 13.1 g's and -13.4 g's, respectively.

#### 4 CONCLUSIONS

Both the AASHTO Guide Specifications for Bridge Rails (5) and NCHRP Report 230 (6) provide specific criteria for evaluating the performance of PL-1 bridge rails. Table 3 summarizes all of the relevant evaluation criteria from these two reports, as well as the findings from the two tests reported herein. As shown in this table, the Steel-Backed Log Rail successfully passed all requirements for performance level 1 bridge rails.

Table 3. Summary of Safety Performance Results

Evaluation Criteria	Results									
	SBLR-1	SBLR-2								
3.a. The test article shall contain the vehicle; neither the vehicle nor its cargo shall penetrate or go over the installation. Controlled lateral deflection of the test article is acceptable.	S	S								
3.b. Detached elements, fragments, or other debris from the test article shall not penetrate or show potential for penetrating the passenger compartment or present undue hazard to other traffic.	S	S								
3.c. Integrity of the passenger compartment must be maintained with no intrusion and essentially no deformation.	S	S								
3.d. The vehicle shall remain upright during and after collision.	S	S								
3.e. The test article shall smoothly redirect the vehicle. A redirection is deemed smooth if the rear of the vehicle does not yaw more than 5 degrees away from the railing from time of impact until the vehicle separates from the railing.	S	S								
3.f. The smoothness of the vehicle-railing interaction is further assessed by the effective coefficient of friction $\mu$ , where $\mu = (\cos\theta - V_p/V)/\sin\theta$ .	M ( $\mu = 1.02$ )	NA
