CONSERVATION AND SURVEY DIVISION

V. H. Dreeszen, Director

The Conservation and Survey Division of the University of Nebraska is the agency designated by statute to investigate and interpret the geologically related natural resources of the state, to make available to the public the results of these investigations, and to assist in the development and conservation of these resources.

The Division is authorized to enter into agreements with federal agencies to engage in cooperative surveys and investigations in the state. Publications of the Division and the cooperating agencies are available from the Conservation and Survey Division, University of Nebraska, Lincoln, Nebraska 68508.

Publication and price lists are furnished upon request.

INVENTORY OF MINING OPERATIONS IN NEBRASKA

Introduction

This report presents an inventory, as of January 1, 1974, of the known past and current Nebraska producers of the following earth materials: limestone; sand, gravel, and silt; clay and shale; sandstone; quartzite; volcanic ash; flint; and coal. Its principal purpose is to assist persons needing up-to-date information on mining operations in the state, on uses made of the mined materials, and on efforts to reclaim mined areas for beneficial use. Those concerned with development and management of the state's mineral resources also will find the current listing of mining operations useful for planning purposes. Similar inventories for 1968 and 1971, prepared by the senior author of this report, are entitled "Directory of quarries, pits, and mines."

Immediately following the text is a series of eight tables. The first seven of these list individual mining operations by county and the eighth summarizes the total number of operations, the acreages affected by those operations, and the affected acreage that has been reclaimed for each type of quarry, pit, or mine in each county.

Table I is a listing of 349 limestone quarries, 40 of which were active as of January 1, 1974. For each is given its location in the township and range system, status (active, inactive, or abandoned), geologic age and name of quarried formation, quarry name, producer's name and address, use made of the limestone, acreage affected, and acreage reclaimed. For some, the type of land treatment subsequent to quarrying is indicated; for some others, the adequacy of the land treatment is noted. Limestone quarries are restricted to counties bordering the Missouri

River downstream from Cedar County, the counties along the south state line west to Franklin County, and all other southeastern counties east and south of Seward County. Cass County has the greatest number of limestone quarries.

Table II lists 607 active and 1,651 inactive or abandoned sand, gravel, and silt pits. For these are given the location, principal material mined (sand, sand and gravel, gravel, or silt), name and address of the producer, use made of mined material, acres affected, and acres reclaimed. The type of land treatment is indicated for most of the reclaimed acreages. Sand and gravel are so widely distributed in the state that only three of the 93 counties are without at least one pit; and since all three of these counties are in (or partly in) the Sand Hills area, none lacks a sand supply. Pits are especially numerous in Cedar, Holt, Hall, Buffalo, Dawson, Lincoln, and Scotts Bluff counties. Silt also is widely distributed, being especially abundant in the eastern and southern counties. However, the number of silt pits is small compared to the abundance of sand and gravel pits. Silt pits, opened in 22 counties, are most numerous in Scotts Bluff, Rock, Brown, and Holt counties.

In table III are listed 24 clay and shale pits, seven of which are active. Given for each is the location and the geologic source of the clay or shale. The plant location, name and address of the producer, and use of the product are shown for all of the active and for several of the abandoned pits. Also given is the acreage affected by the operation and the acreage reclaimed. All the pits are in eastern or southeastern counties.

Data on 72 sandstone quarries, 15 of which are active, are listed in table IV. The location of each quarry and the geologic formation that is quarried are given. If known, the quarry name, the name and address of the producer, and the use of the product are indicated. The acreage affected by the quarrying operation and the acreage reclaimed are also shown. Of the 17 counties in which sandstone quarries are located, Keya Paha has the greatest number.

Table V lists eight quartzite quarries, all in Frontier, Redwillow, and Franklin counties. These quarries, now abandoned, were operated by the U.S. Corps of Engineers or the U.S. Bureau of Reclamation to obtain riprap for the facing of dams. The location, acreage mined, and acreage reclaimed are indicated for each of the quarries.

Twenty-seven volcanic ash pits are listed in table VI. Only one of these, in northeast Lincoln County, was active as of January 1, 1974. The location, use of the ash, acreage mined, and acreage reclaimed are shown for each pit. The location of the plant, name of the producer, and type of land treatment are indicated for several pits.

Table VII is a catchall for pits, quarries, and mines other than those of types includable in the foregoing table. Data are given for three flint quarries, one chalk mine, and one coal mine. The location, acreage mined, and acreage reclaimed are shown for each.

Table VIII gives for each county the total number of mining operations and estimated total acreages mined and reclaimed. It gives also the same information for each type of quarry, pit, or mine.

Summary of Mining Operations in Nebraska

A total of 2,744 quarries, pits, and mines are known to have been operated in the state within the past half century. Of this number, 349 are limestone quarries, 2,258 are sand, gravel and silt pits, 24 are clay or shale pits, 72 are sandstone quarries, 8 are quartzite quarries, 28 are volcanic ash pits, three are flint quarries, one is a chalk pit, and one is a coal mine. These operations affected 29,444 acres of land, more than one-fourth of which have been reclaimed or converted to some useful purpose.

In 1973 there were 670 quarries and pits operated in the state. These comprised 40 limestone quarries; 607 sand, gravel, and silt pits; 7 clay and shale pits; 15 sandstone quarries; and

one volcanic ash pit. Of the 1,300 acres disturbed by mining operations in 1973, 281 were restored for other uses.

Geologic and Mineral Resource Maps

Copies of two previously published maps compiled by the senior author are included with this report. One, the "Geologic Bedrock Map of Nebraska," shows where various rock units would be at the surface if the mantle of soil and unconsolidated Quaternary deposits were not present. These rock units are of Pennsylvanian, Permian, Cretaceous, and Tertiary ages. Together with the Quaternary deposits, these rocks are the sources of all minerals now being produced in Nebraska. The other map, "Mineral Resource Map of Nebraska," shows the sites of pits, quarries, and mines where sand and gravel, sandstone, silt or siltstone, clay or shale, volcanic ash, and limestone have been or are being produced commercially. Also shown are the locations of oil and gas fields. Nine maps of smaller scale show the surface and near-surface occurrences of sand and gravel, quartzite, limestone, uranium-bearing rocks, clay or shale, bentonite, volcanic ash, gypsum, and diatomaceous earth. Five other small-scale maps show occurrences of sodium and potassium salt, potential occurrence of metallic minerals, availability of large and small supplies of groundwater, locations of underground gas storage, and configuration of the Precambrian rock surface.

Composite Geologic Section

As shown by the chart on the following page, the rocks beneath Nebraska represent all the geologic periods. However, only rocks of Pennsylvanian, Permian, Cretaceous, Tertiary, and Quaternary age are exposed, the others being limited to the subsurface. Those of Precambrian age, consisting of igneous and metamorphic rock, underlie the entire state. These are overlain by stratified rocks ranging in thickness from a little more than

COMPOSITE GEOLOGIC SECTION

GEOLOGIC PERIOD	ROCK TYPES	MINERAL RESOURCES AND PRODUCTS
QUATERNARY	Till, silt, clay, sand, gravel, and volcanic ash	Agricultural soil, water, sand and gravel, and volcanic ash
TERTIARY	Sandstone, siltstone, clay, gravel, marl, volcanic ash, and quartzite	Agricultural soil, water, sand and gravel, volcanic ash, and riprap
CRETACEOUS	Chalk, chalky shale, dark shale, varicolored clay, sandstone, and conglomerate	Water, oil and gas, coal, agricultural lime, and components of cement, brick, and other construction materials
JURASSIC	Sandstone and shale (sub-surface only)	
TRIASSIC		
PERMIAN	Shale, limestone, dolomite, gypsum, anhydrite, sandstone, siltstone, and chert	Water, agricultural lime, oil, road rock, and riprap
PENNSYLVANIAN	Limestone, shale, sandstone, and coal	Oil, concrete aggregate, light-weight aggregate, road rock, coal, agricultural lime, riprap, water, and components of cement and brick
MISSISSIPPIAN	Limestone and dolomite (sub-surface only)	Oil and water
DEVONIAN	Dolomite and shale (sub-surface only)	
SILURIAN	Dolomite (subsurface only)	
ORDOVICIAN	Dolomite, sandstone, and shale (subsurface only)	
CAMBRIAN	Dolomite and sandstone (sub-surface only)	
PRECAMBRIAN	Granite, other igneous rocks, and metamorphic rocks (sub-surface only)	Potential occurrence of metallic minerals

500 feet locally in southeastern Nebraska (specifically in southeastern Pawnee County) to an estimated 10,000 feet in the southwestern part of the panhandle area. Rocks of all geologic periods younger than Precambrian are of less than statewide extent; however, those of several periods extend throughout more than half the state's area.

Occurrence and Use of Mineral Resources

Limestone is exposed or is thinly mantled by unconsolidated deposits in many places in eastern Nebraska, where strata of Pennsylvanian, Permian, and Cretaceous age constitute the uppermost bedrock. All the limestone quarries are in this part of the state. Although limestone is present beneath most of the remainder of Nebraska, it is too deeply buried there to be mined profitably at the present time. Crushed limestone is used as aggregate in concrete and asphalt, as surfacing for roads, as riprap, and in the manufacture of cement, agricultural lime, and mineral filler. Sized limestone blocks are used for retaining walls and walls of buildings.

Sand, gravel, and silt are abundant natural resources in Nebraska. Most minable deposits of sand and gravel are beneath the bottom land or terraces in the larger valleys and are of Quaternary age. Some sand and gravel deposits are in the Ogallala Formation of Tertiary age and occur in both upland and valley situations. Silt, another component of Tertiary and Quaternary deposits, is widely distributed in the state. The principal use of sand and gravel is for aggregate in concrete for building or paving; other uses include aggregate for asphalt, roadstone, and fill. Silt is used mainly for fill and for base material.

Clay and shale is obtained from the Scranton Limestone, Willard Shale, Pillsbury Shale, and Stotler Shale of Pennsylvanian age and the Dakota Group of Cretaceous age. Pennsylvanian rocks are exposed or are near the surface only in the southeastern counties, and the Dakota Group is at or near the surface in many

places along a wide band extending north-northeastward from Thayer and Jefferson counties in the south to Dakota County in the north. Clay and shale are used mainly in the manufacture of brick, tile, pottery, lightweight aggregate, and cement. Brick plants near Endicott, Lincoln, and Omaha use clay and shale of Cretaceous age. A plant near Nebraska City produces lightweight aggregate from Pennsylvanian shales that formerly were used in making brick. Plants near Louisville and Superior mix clay and shale of Cretaceous age with limestone to produce cement; the limestone used at the Louisville plant is of Pennsylvanian age and at the Superior plant is of Cretaceous age.

Sandstone is a component of four widely exposed rock units--the Dakota Group of Cretaceous age and the Brule Formation, Arikaree Group, and Ogallala Formation of Tertiary age. All sandstone quarries in eastern Nebraska are in the Dakota, and those in the north-central and western parts are in Tertiary formations. Crushed sandstone is used for road surfacing and fill.

Quartzite is known to occur in the Ogallala Formation at several sites in the north-central and south-central parts of the state. The rock is very hard, extremely durable, and, in some places, of greenish color. Quartzite produced by the quarries listed in table V was used as riprap for facing dams in the Republican River basin. Similar quartzite has been used for street paving, retaining walls, and buildings at a few places in the state, but the sites of the quarries producing that quartzite are not known.

Volcanic ash occurs at several horizons in Tertiary and Quaternary rocks. Although some deposits are too thin or too intermixed with other materials to be of commercial value, minable deposits occur in several places in Nebraska. Volcanic ash has two principal uses: as a filler in paints and some other products and as a component of scouring compounds.

Flint is a siliceous rock that breaks with a conchoidal fracture and sharp edge. It occurs as nodules and irregular concretions in softer rock such as chalk and limestone. Sites where Indians fashioned arrowheads from flint have been found at

several places in Nebraska. The only known commercial production in the state was from the Florence Limestone of Permian age. The flint was mined for railroad ballast.

Chalk is a soft, white to light gray, unindurated limestone that is used for filler in paint, as a soil additive, in the manufacture of marking sticks, and as building stone. The one chalk mine in Nebraska was at Scotia, in southwestern Greeley County; the source was the Ogallala Formation of Tertiary age. Since the mine was abandoned, a state-owned wayside park has been established at its site.

Coal, an organic rock formed by the accumulation and decomposition of plant material, is a minor component of Pennsylvanian rocks in southeastern Nebraska and certain Cretaceous rocks in western Nebraska. Only the seams in Pennsylvanian rocks are exposed. Several small mines provided fuel for heating of homes in the immediate vicinity; the only commercial mine operation was shortlived.
