# Abstract

Previous research of sequential investment strategies for portfolio selection have shown that there are strategies that exist that can beat the best stock in the market. In this dissertation, an algorithm is presented that uses a nearest neighbour approach similar to the one used by Györfi *et al* [20, 21, 22]. The approach is however extended to include zero-cost portfolios and uses a quadratic approximation, instead of an optimisation step, to determine how capital should be allocated in the portfolio based on the neighbours that have been found. A portfolio that results in an increase in the investor's capital and compares favourably to certain benchmarks, such as the best stock, indicates that there are patterns in the time series data. Other features of the algorithm presented is to allow for the data to be clustered by a selection of stocks or partitioned based on time. The algorithm is tested on synthetic datasets that depict different market types and is shown to accurately determine trends in the data. The algorithm is then tested on real data from the New York Stock Exchange (NYSE) and data from the Johannesburg Stock Exchange (JSE). The results of the algorithm from the real datasets are compared to implemented versions of past strategies from the literature and compares favourably.

# Acknowledgements

First and foremost, I would like to thank my supervisor, Prof. Tim Gebbie, for his continuous support and guidance during my MSc journey. I also thank him for providing me with this topic and for the initial research and code development that was required for this topic. I am truly grateful to have had Prof. Tim Gebbie as my supervisor for my MSc study.

I would also like to thank Prof Turgay Celik for his input in various conversations. I would like to thank Prof Diane Wilcox and the entire QuERI Lab team for the helpful discussions and suggestions that they offered. I extend this thanks to the entire Computer Science and Applied Mathematics department for their hospitality and fantastic academic environment that they have created.

My sincere thanks go to Mr. Shunmuga Pillay, Mr. Brian Maistry and Mr. Mohsin Desai for their assistance in setting up a MATLAB Distributed Computing Server on the Hydra cluster and for all the help that they offered during my time in the Mathematical Sciences Labs.

I would like to thank the National Research Foundation (NRF) for the financial assistance provided towards this research<sup>1</sup>.

Finally, I would like to thank my parents, my sisters and my friends for their moral support and motivation offered during my post graduate studies.

---

<sup>1</sup>This research is not necessarily attributed to the NRF

# Declaration

I, Fayyaz Loonat, hereby declare that this dissertation titled *Agent-Based Learning for Pattern Matching in High-Frequency Trade Data* is my own work except where reference has been made to published literature. I further declare that this dissertation has not been previously submitted for any degree at any university.

**Candidate:** Fayyaz Loonat

**Signature:** \_\_\_\_\_

**Date:** \_\_\_\_\_

# Publications and Pre-Prints

There is one pre-print available for this research at [arxiv.org](https://arxiv.org) [18] and is titled “Learning zero-cost portfolio selection with pattern matching”.

# Chapter 1

## Introduction

In this dissertation, an algorithm that uses a pattern matching approach for zero-cost portfolio selection for sequential investment strategies is presented. Sequential investment strategies are strategies that use past behaviour to determine how an investor can allocate their wealth amongst a number of assets in a portfolio [6, 10, 45, 25, 8]. Previous strategies of portfolio selection for sequential investment presented by several authors [6, 10, 45, 25, 8] only considered investors holding long only positions on the assets. The algorithm presented in this dissertation and described in Gebbie and Loonat [18] allows the investor to hold a short position on some assets and a long position on the remainder of the assets to arrive at a portfolio that is a zero cost portfolio.

As described in a survey by Li *et al* [33], the Universal Portfolios approach investigated by Cover [10] and the Exponentiated Gradient approach investigated by Helmbold *et al* [25] can be classified as follow the winner approaches. Various agent-based (‘experts’) pattern matching approaches, each using a different criteria for classifying matches and patterns, have been investigated by Györfi *et al* [20, 21, 22]. Similar to the strategies discussed in the survey by Li *et al* [33], this dissertation aims to demonstrate that the algorithm can beat the best stock in the market, this would infer that the algorithm has successfully found patterns in the time series data. This dissertation also aims to investigate how an analytic approach, derived using the mutual fund separation theorem [31], compares to an optimisation approach in terms of accuracy versus running time.

The literature review in Chapter 2 has an in depth discussion of the Universal Portfolios approach by Cover *et al* [10] and the four algorithms (Histogram, Kernel, Nearest Neighbour and First Neighbour) introduced by Györfi *et al* [20, 21, 22]. These approaches are discussed in depth because the results obtained by the Universal Portfolios approach presented in Cover *et al* [10] and results obtained from the Nearest Neighbour approach presented in Györfi *et al* [21] are compared to the results obtained from the algorithm in this dissertation. Attempts at recovering the results in [10, 21] are achieved by implementing a version of the Universal Portfolios approach and Nearest Neighbour approach, these recovered implementations are used to compare results achieved by the algorithm on datasets not investigated in Cover *et al* [10] and Györfi *et al* [21], namely the extended NYSE dataset (referred to as NYSE Merged) and the JSE datasets. A discussion on thick modelling based on the work of [3] and [46] is also discussed. An overview of the Borodin *et al* paper titled “Can We Learn to Beat the Best

Stock” is presented to demonstrate an alternate approach to portfolio selection and the interesting extensions that their ANTICOR algorithm implements. A summary of the Li and Hoi [33] survey is also included in Chapter 2 to give an overview of portfolio selection techniques from published literature.

Chapter 3 provides a detailed description of the derivation of the algorithm that is presented as well as pseudocode for the algorithms. The algorithm is inspired by the Györfi *et al* Nearest Neighbour algorithm [21] but has been extended to include zero-cost (active) portfolios and a quadratic approximation instead of an optimisation step to determine the portfolio used. The algorithm is also presented in an online form, however it is important to note that while the algorithm does use online learning [8, 41, 40, 15], the pattern matching is not truly online.

A summary of the datasets used is given in Chapter 4. The data used is in price relative format or is converted into price relative format. A price relative is the ratio of the price of a stock at time  $t$  to the price of the stock at time  $t - 1$ . There are four sets of real data, two New York Stock Exchange (NYSE) datasets obtained from [19] and two Johannesburg Stock Exchange (JSE) datasets obtained from [47] and they will be referred to as:

1. NYSE
2. NYSE Merged
3. JSE OHLC
4. JSE Intraday

There are four sets on synthetic data (SDC) each portraying a market with a certain characteristic, the characteristics are as follows:

- i. A market without significant growth in the price of the stocks. (see section 4.1.1)
- ii. A market where the price increases over time. (see section 4.1.2)
- iii. A market where a stock can either increase or decrease over time based on a random variable. (see section 4.1.3)
- iv. A market where a few stocks increase over time and a few stocks decrease over time. (see section 4.1.4)

Chapter 5 discusses the results of Kolmogorov-Smirnov tests on the synthetic datasets to ensure that the algorithm behaves as expected for each of the different market characteristics. Chapter 5 also describes the process used to implement the algorithms presented in Chapter 3, and compares the performance of the methods discussed in Chapter 2 to the actual results obtained from the algorithms on the datasets described in Chapter 4.

The MATLAB code that has been used is included in Appendix A of this dissertation.

# Chapter 2

## Literature Review

### 2.1 Universal Portfolios

Thomas M. Cover describes the Universal Portfolios algorithm for portfolio selection in [10]. The goal wealth of the Universal Portfolio is the wealth achieved by the best constant rebalanced portfolio. A constant rebalanced portfolio is a portfolio that fixes the fraction of an investor's wealth that is assigned to each stock and rebalances the wealth at these same fractions at the beginning of each trading period. The notation used by Cover in [10] represents the stock market vector by  $\mathbf{x} = (x_1, x_2, \dots, x_m)$ , where  $x_i$  is the price relative of the  $i$ th stock.  $\mathbf{b} = (b_1, b_2, \dots, b_m)$  denotes the portfolio of the investor, where  $b_i$  is the fraction of the investors wealth assigned to stock  $i$ .  $S_n$  denotes the wealth achieved by the portfolio at time  $n$  and the total number of stocks is  $m$ .  $\hat{\mathbf{b}}$  and  $\hat{S}_n$  represent the universal portfolio and the wealth achieved by the universal portfolio respectively.

The Universal Portfolio strategy is a performance weighted strategy and is initialised by assigning the same fraction of wealth to each of the stocks as follows:

$$\hat{\mathbf{b}}_1 = \left(\frac{1}{m}, \frac{1}{m}, \dots, \frac{1}{m}\right) \quad (2.1)$$

$$\hat{\mathbf{b}}_{k+1} = \frac{\int \mathbf{b} S_k(\mathbf{b}) d\mathbf{b}}{\int S_k(\mathbf{b}) d\mathbf{b}} \quad (2.2)$$

where  $S_k(\mathbf{b}) = \prod_{i=1}^k \mathbf{b}^t \mathbf{x}_i$

The integration is over the set  $B = \{\mathbf{b} \in \mathbb{R}^m : b_i \geq 0, \sum_{i=1}^m b_i = 1\}$  and the wealth of the universal portfolio is given by  $\hat{S}_n = \prod_{k=1}^n \hat{\mathbf{b}}_k^t \mathbf{x}_k$ .

Cover [10] tests the Universal Portfolios algorithm on real data from the New York Stock Exchange over a 22 year period from 1963 to 1985. The results obtained are for  $m = 2$  stocks and the integrals are all quantised. The quantisation is done as follows:

$$\hat{b}_{k+1} = \int_0^1 \frac{b S_k(b) d\mathbf{b}}{\int_0^1 S_k(b) d\mathbf{b}} \text{ is replaced by } \hat{b}_{k+1} = \frac{\sum_{i=0}^{20} \frac{i}{20} S_k(\frac{i}{20})}{\sum_{i=0}^{20} S_k(\frac{i}{20})} \quad (2.3)$$

$$\hat{S}_n = \prod_{k=1}^n \hat{\mathbf{b}}_k^t \mathbf{x}_k \text{ is calculated using } \hat{b}_k = \frac{\sum_{i=0}^{20} \frac{i}{20} S_k(\frac{i}{20})}{\sum_{i=0}^{20} S_k(\frac{i}{20})} \quad (2.4)$$

Thomas M. Cover shows that the Universal Portfolio method can perform better than a buy and hold strategy of a single stock.

### 2.1.1 Recovering Prior Results

Using the same data from the New York Stock Exchange that was used in [10], the results that were obtained were recovered. Figure 2.1 shows that the Universal Portfolio strategy when tested on 2 stocks, Iroquois Brands Ltd. and Kin Ark Corp., outperforms buy and hold strategies for those stocks.

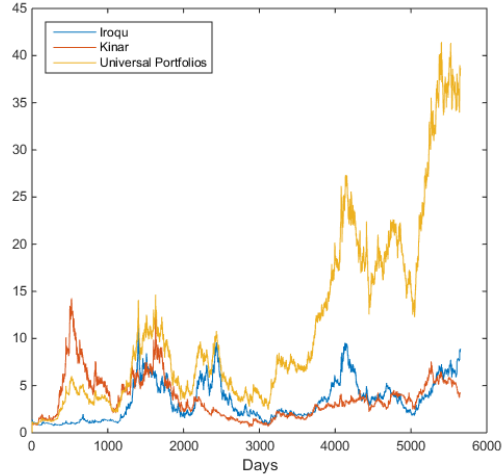

FIGURE 8.3. Performance of universal portfolio.

(a) Figure taken from Cover [10].

(b) Figure generated in MATLAB using the code from Appendix A.2

Figure 2.1: Wealth gained from the Universal Portfolios strategy.

Figure 2.2 shows the fraction of the investors wealth assigned to Iroquois Brands Ltd. on each trading day using the Universal Portfolio strategy. Using the method outlined in [10], the results were recovered using MATLAB.

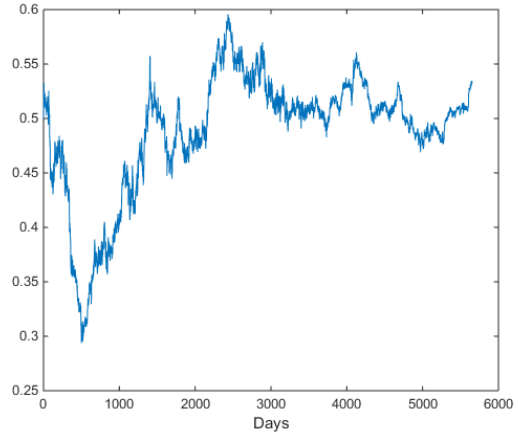

FIGURE 8.4. The portfolio  $\hat{\mathbf{b}}_k$ .

(b) Figure generated in MATLAB using the code from Appendix A.2

Figure 2.2: Fraction of wealth allocated to Iroquois Brands Ltd.

## 2.2 Györfi *et al* Algorithms

Four algorithms for portfolio selection are introduced by Györfi *et al* in [20], [21] and [22]. They all have a similar structure, where the algorithm looks at the past  $k$  days and searches through the entire history to find  $k$  days in the history that are similar to the past  $k$  days. The algorithms differ in the manner in which matches are defined, how many matches to find and which partitions of the history the algorithm should search. Each algorithm defines an array of ‘experts’  $\mathbf{H}^{(k,\ell)} = \{\mathbf{h}^{(k,\ell)}(\cdot)\}$  where  $k, \ell > 0$  are integers,  $k$  is the period length and  $\ell$  is used to determine the matching criteria. A positive probability distribution  $q_{k,\ell}$  is used to combine the experts such that the investor’s capital becomes:

$$S_n(\mathbf{B}) = \sum_{k,\ell} q_{k,\ell} S_n(H^{(k,\ell)}) \quad (2.5)$$

The following notation is used to describe these algorithms in [20], [21] and [22]:

- i.  $\mathbf{x}_i$  denotes the return vector at time  $i$ . The return vector contains the price relatives for each of the stocks.
- ii.  $\mathbf{x}_{i-k}^{i-1}$  denotes the return vectors from time  $i - k$  to time  $i - 1$ .
- iii.  $\mathbf{b}$  denotes the portfolio vector, the fraction of wealth assigned to each stock.

## 2.2.1 Histogram Strategy

The idea of the histogram strategy is to assign integer values to the price relatives in the stock market vector. The partitions used in [20] is determined by using constants  $a$  and  $w$  which are determined by  $\ell \in 1, 2, \dots, L$ .

$$a = \frac{1}{2(1 + 2\log_{10} \ell)} \quad \text{and} \quad w = a^{\frac{-1}{\ell}}$$

Here  $x$  is the price relative of a stock and  $q$  is the integer assigned to the corresponding price relative.  $M = 2 + 2(\ell)$  represents the total number of price relative partitions.

$$q = \begin{cases} 0 & : x \leq a \\ 1 + \left\lfloor \frac{\log_{10}(\frac{x}{a})}{\log_{10}(w)} \right\rfloor & : x \in (a, 1] \\ \ell + 1 + \left\lfloor \frac{\log_{10}(ax) + \ell \log_{10}(w)}{\log_{10}(w)} \right\rfloor & : x \in (1, \frac{1}{a}] \\ 2\ell + 1 & : x > \frac{1}{a} \end{cases}$$

Figure 2.3: A plot of the partitioning function produced in Mathematica when  $\ell = 4$  and  $M = 2 + 2(4) = 10$ .

Figure 2.3<sup>1</sup> shows a possible way of partitioning the stock market vectors, the x-axis represents the value of the price relative and the y-axis represents the integer associate with the price relative. It can be observed that there is more integer bands closer to one. A function  $G_\ell(\mathbf{x})$  represents the

<sup>1</sup>The Mathematica notebook used to produced the figure is available at <https://github.com/FayyazL/Pattern>

discretisation of the stock market vector and the set of matches  $J$  is defined as follows:

$$J_{k,\ell,n} = \{k < i < n : G_\ell(x_{i-k}^{i-1}) = G_\ell(x_{n-k}^{n-1})\}$$

For each  $n > k + 1$  the best constant rebalanced portfolio is found, using optimisation, over the stock return vectors at times  $i \in J_{k,\ell,n}$ . The experts can be formally defined as:

$$\mathbf{h}^{(k,\ell)}(\mathbf{x}_1^{n-1}) = \arg \max_b \prod_{i \in J_{k,\ell,n}} \langle \mathbf{b}, \mathbf{x}_i \rangle$$

## 2.2.2 Kernel Strategy

The kernel strategy defines the set of matches at time  $n$  with the following set:

$$J_{k,\ell,n} = \{k < i < n : \|x_{i-k}^{i-1} - x_{n-k}^{n-1}\| \leq r_{k,\ell}\}$$

The general idea with the kernel method is to find the times  $i$  in the history where the norm of the difference between the past  $k$  days at time  $n$  and the past  $k$  days at times  $i$  is less than a radius  $r_{k,\ell}$  which is defined in terms of  $k$  and  $\ell$ . A disadvantage of this method is that if  $r_{k,\ell}$  is too small then very few or no matches could be found and if  $r_{k,\ell}$  is too large then too many matches will be found. The experts are formally defined as follows and solved using optimisation:

$$\mathbf{h}^{(k,\ell)}(\mathbf{x}_1^{n-1}) = \arg \max_b \prod_{i \in J_{k,\ell,n}} \langle \mathbf{b}, \mathbf{x}_i \rangle$$

## 2.2.3 Nearest Neighbour Strategy

The nearest neighbour algorithm that is introduced in [21] and [22] is similar to the kernel strategy, however instead of using a radius the nearest neighbour strategy uses an integer  $\hat{\ell}$  to determine how many nearest neighbour matches to use. [21] and [22] formally define the strategy as follows:

$$\hat{\ell} = \lfloor p_\ell n \rfloor$$

Where  $p_\ell \in (0, 1)$  and  $n$  is time.

The  $p_\ell$  used in the results section of [21] is defined as:

$$p_\ell = 0.02 + 0.5 \frac{\ell - 1}{L - 1}$$

where  $\ell = 1, \dots, L$ .

The set of matches is defined as:

$$J_{k,\ell,n} = \{i : k + 1 < i < n \text{ such that } x_{i-k}^{i-1} \text{ is among the } \hat{\ell} \text{ nearest neighbours} \}$$

The experts are defined as follows and is solved using optimisation:

$$\mathbf{h}^{(k,\ell)}(\mathbf{x}_1^{n-1}) = \arg \max_b \prod_{i \in J_{k,\ell,n}} \langle \mathbf{b}, \mathbf{x}_i \rangle$$

## 2.2.4 First Neighbour Strategy

The first neighbour strategy is a variant of the nearest neighbour strategy and is implemented because it is computationally faster than the nearest neighbour strategy. The idea is to split the history up into segments and to search for the best match in each of the segments. This is done by using a term  $s_\ell$  to denote the segment length and is defined in the paper as  $s_\ell = 2 + 50 \frac{\ell-1}{L-1}$ . The strategy can be formally written as follows:

$$N_i = \arg \min_{(i-1)s_\ell + k \leq j \leq i s_\ell} \|x_{j-k}^{j-1} - x_{n-k}^{n-1}\|$$

Here  $N_i$  is the instant of the nearest neighbour match in the  $i$ th segment and the experts are defined as follows and solved using optimisation:

$$\mathbf{h}^{(k,\ell)}(\mathbf{x}_1^{n-1}) = \arg \max_b \prod_{1 \leq i \leq \lfloor \frac{n-1}{s_\ell} \rfloor} \langle \mathbf{b}, \mathbf{x}_i \rangle$$

## 2.2.5 Recovering Prior Results

In table 2.1, a comparison of the results obtained from the nearest neighbour strategy by Györfi *et al* in [22] and the results obtained from implementing a recovered version of the Nearest Neighbour algorithm is shown. The experiments were carried out for the experts using  $k = 1, \dots, 5$  and  $\ell = 1, \dots, 10$ . It can be observed that values obtained in the recovery attempt has the same order of magnitude as the values obtained in [22]. Only the Nearest Neighbour Strategy has been recovered as this showed to be the best performer [21] and is the approach that the algorithm in this dissertation extends by using a cash neutral portfolio (active portfolio) and a quadratic approximation instead of an optimisation step.

<b>Stocks</b>	<b>Györfi <i>et al</i></b>		<b>Recovered</b>	
Iroquois	Best Agent	1.439e+13	Best Agent	1.629e+13
Kin Ark	Total Wealth:	1.156e+12	Total Wealth:	8.9729e+11
Com Met.	Best Agent	3.148e+4	Best Agent	2.601e+04
Mei. Corp	Total Wealth:	3.505e+3	Total Wealth:	3.8402e+3
Com. Met.	Best Agent	8.257e+13	Best Agent	3.748e+13
Kin Ark	Total Wealth:	4.781e+12	Total Wealth:	2.7121e+12
IBM	Best Agent	296.3	Best Agent	267.440
Coca-Cola	Total Wealth:	74.37	Total Wealth:	80.9688

Table 2.1: Recovering the prior results of the Györfi *et al* [21] Nearest Neighbour algorithm using the MATLAB code in Appendix A.1

The difference between the results from Györfi *et al* [22] and the recovered results may be attributed to two possible reasons, the optimisation method used and the initialisation of the agents. The optimisation method used in the literature as stated in [22] is Spellucci’s DONLP2 [51] method which is a variant of the sequential quadratic programming method, while the method used to recover the results is MATLAB’s `fmincon` method which uses a gradient descent method [44]. In Györfi *et al* [21], it is suggested that the agents are initialised at time  $k + 1$  and in the implementation of the algorithm in this dissertation the algorithm is initialised at time  $3\ell$ .

Although the results from the literature and the results obtained from the recovered implementation of the Nearest Neighbour are not exact, it does have the same order of magnitude as observed in table 2.1. This allows for an accurate comparison of the methods on datasets not experimented on in [21].

## 2.3 Thick Modelling

Pesaran and Timmerman [46] investigate the predictability of stock returns by applying a recursive modelling approach to predict all possible forecasting models and the stock returns are predicted based on the best model. Aiolfi and Favero [3] describe this approach as thin modelling because the approach uses only the best model to forecast the returns.

Aiolfi and Favero [3] extend the approach of predicting stock returns of Pesaran and Timmerman [46] to one that is based on thick modelling. Thick modelling is achieved by considering more multiples of the predicted possible forecasting models [2, 3].

An interesting result in [3] is that the results of thin modelling approach of Pesaran and Timmerman [46] are weakened in the decade 1990-2000.

It can be observed that the approach used in this dissertation is one of thick modelling that does not

rely on the best result but rather multiple results to determine portfolio selection.

## 2.4 “Can We Learn to Beat the Best Stock”

Borodin, Yaniv and Gogan [8] present the ANTICOR method in their paper *Can we learn to beat the best stock*. An alternate approach to portfolio selection is taken where the ANTICOR algorithm uses statistical relations between stocks to determine the portfolio to be used in the next trading period.

The approach of the ANTICOR algorithm is to define two consecutive trading windows formulated as  $[t - 2w + 1, t - w]$  and  $[t - w + 1, t]$ , where  $w$  is the number of trading days in the window. Borodin *et al* [8] uses the logarithm of the price relatives in these trading windows and calculates the cross correlation matrix of the two trading windows [33]. Borodin *et al* [8] shows that the performance of the ANTICOR algorithm relies on the choice of the trading window  $w$ . In order to learn the best  $w$ , Borodin *et al* [8] defines  $\text{ANTI}^1$  which uses experts (agents) with window lengths ranging from  $2 \leq w \leq 30$  that each has a uniform buy and hold investment.

An interesting approach used by Borodin *et al* [8] is to extend the approach from purely trading on the stocks to trading on the algorithms. This approach is denoted as  $\text{ANTI}^2$  and trades on the algorithms from  $\text{ANTI}^1$ . It is shown that the results achieved from this compounding significantly improves the performance of the portfolio.

Another interesting result of [8] is that the algorithm is not only tested on the NYSE data set [19] but is further tested on the Toronto Stock Exchange (TSE), 25 stocks from the SP500 and 30 stocks composing the Dow Jones Industrial Average (DJIA). The four markets are then reversed and experimented on to ensure that the algorithm performs favourably on markets that are different in nature.

## 2.5 “Online Portfolio Selection: A Survey”

Li and Hoi [33] provide a comprehensive survey on portfolio selection that discusses 25 techniques from published literature. These techniques are classified into the following 5 categories:

1. Benchmarks
2. Follow the Winner
3. Follow the Loser
4. Pattern-Matching-Based Approaches
5. Meta-Learning Algorithms

The techniques classified as benchmarks are the buy-and-hold strategy, the best stock strategy and the constant rebalanced portfolios strategy. These strategies are merely used, as the classification

suggests, as a benchmark for the other strategies. Cover [10] states that his Universal Portfolios strategy aims to beat the best stock and sets the best constant rebalanced portfolio as a target wealth for the strategy. A buy-and-hold strategy is where stocks are bought in the first period and no rebalancing is done.

Techniques that rebalance the portfolio based on the assets that are performing well are classified as Follow the Winner approaches. The Universal Portfolios strategy of Cover [10] can be classified as such an approach and is discussed in detail in Section 2.1. Another strategy classified as a Follow the Winner approach is the Exponential Gradient strategy proposed by Helmbold *et al* [25] which tracks the stock with the best performance but does not drastically change the updated portfolio in comparison to the previous portfolio. The approach proposed by Gaivoronski and Stella [17] that tracks the best constant rebalanced portfolio, the Online Newton Step approach proposed by Agarwal *et al* [1] and the aggregating approach proposed by Vovk and Watkins [53] that uses a finite set of investment strategies that an investor would consider to be reasonable have also been classified as strategies that are Follow the Winner approaches.

Follow the Loser approaches, based on the principle of mean reversion, uses the idea that if a stock performs poorly in the current period it will perform well in the following periods and that if a stock is performing well in the current period it will perform poorly in the following periods. The ANTICOR strategy presented by Borodin *et al* [8] and discussed in section 2.4 has been classified as a Follow the Loser approach. Other strategies classified as Follow the Loser approaches are the Passive Aggressive Mean Reversion approach in [36] and the Confidence Weighted Mean Reversion approach in [35] proposed by Li *et al* which is named based on the online learning chosen. The Online Moving Average Reversion proposed by Li and Hoi [32] is also classified as a Follow the Loser approach.

The Györfi *et al* [20, 21, 22] approaches, outlined in Section 2.2, along with the correlation driven nonparametric learning approach proposed by Li *et al* [34] have been classified as pattern matching based approaches and are described to have two steps. The first step is the sample selection and the second step is the portfolio optimisation.

Approaches classified as Meta-Learning Algorithms are approaches similar to Follow the Winner approaches but has a broader class of experts. Vovk and Watkins [53] Aggregating Algorithms is classified as both a Follow the Winner approach and a Meta-Learning Algorithm. Fast Universalisation proposed by Akcoglu *et al* [4, 5], an extension of Universal Portfolios [10], is also classified as a Meta-Learning Algorithm because it uses a wide class of investment strategies apart from the best constant rebalanced portfolios. Online Gradient and Newton Updates proposed by Das and Banerjee [14], which is an extension of the Exponential Gradient [25] and Online Newton Step [1], and the Follow the Leading history approach proposed by Hazan and Seshadhri [24], which has a working set of experts dynamically flowed in and dropped out, are also classified as Meta-Learning Algorithms.

# Chapter 3

## Algorithm

### 3.1 The Algorithm and Mathematical Model

The model that is used in this dissertation has a similar structure the model used by Györfi *et al* [20, 21, 22] and Cover *et al* [10]. The price relative of each stock is denoted by:

$$x_{m,t} = \frac{p_{m,t}}{p_{m,t-1}} \quad (3.1)$$

Where  $x_{m,t}$  is the price relative of stock  $m$  at time  $t$  and  $p_{m,t}$  is the price of stock  $m$  at time  $t$ . Equivalently written in vector form as  $\mathbf{x}_t$ .

The algorithm is formally defined as 3 algorithms and is based on the Györfi *et al* [21] Nearest Neighbour algorithm, it is however extended to include zero cost (cash neutral) portfolios and uses an analytic quadratic approximation instead of an optimisation step to determine the portfolio selection. Algorithm 1 is named the Online-Learning Algorithm (OLA), Algorithm 2 is named the Pattern Matching Algorithm (PMA) and Algorithm 3 is named the Matching Algorithm (MTA).

The Online-Learning Algorithm serves the purpose of managing the portfolio. It takes in as input the portfolio controls  $b_{m,t}$ , the agent controls  $H_{n,t}$ , the updated agent controls  $H_{n,t+1}$ , the feature realisation  $x_t$ , the past agent wealth  $S_{n,t-1}$  and the past portfolio wealth  $S_{t-1}$ .

$b_{m,t}$  denotes the fraction of the portfolio's wealth allocated to stock  $m$  at time  $t$  and is referred to as the portfolio controls.  $S_t$  denotes the portfolio wealth and is updated as follows:

$$\Delta S_t = \left[ \sum_m b_{m,t}(x_{m,t} - 1) \right] + 1 \quad (3.2)$$

$$S_t = S_{t-1} \Delta S_t. \quad (3.3)$$

$H_{m,t}$  denotes the fraction of an agents wealth allocated to stock  $m$  at time  $t$  and is referred to as the

agents controls.  $S_{n,t}$  denotes the agent wealth and is updated as follows:

$$\Delta S_{n,t} = \left[ \sum_m H_{nm,t}(x_{m,t} - 1) \right] + 1. \quad (3.4)$$

$$S_{n,t} = S_{n,t-1} \Delta S_{n,t}. \quad (3.5)$$

The portfolio controls  $b_{m,t}$  is updated using the agent controls as follows:

$$b_{m,t+1} = \sum_n q_{n,t+1} H_{nm,t+1}. \quad (3.6)$$

Where  $q_{n,t+1}$  represents the agent mixer control for agent  $n$  at time  $t + 1$ . The agent mixer control is determined by an agent mixer update rule which will be referred to as rule  $g$ . The following mixture update rules are considered:

(a) **Universal Portfolio**

The Universal Portfolios update mixture rule, inspired by Cover *et al* [10], is calculated as follows:

$$q_{n,t+1} = S_{n,t} \quad (3.7)$$

The agent mixtures at time  $t+1$  is proportional to the wealth achieved by the agents at time  $t$ .

(b) **Exponential Gradient**

$$q_{n,t+1} = q_{n,t} e^{\left( \frac{\eta S_{n,t}}{\sum_n q_{n,t} S_{n,t}} \right)} \quad (3.8)$$

(c) **Exponential Weighted Moving Average**

$$q_{n,t+1} = \lambda q_{n,t} + (1 - \lambda) \left( \frac{q_{n,t} S_{n,t}}{\sum_n q_{n,t} S_{n,t}} \right) \quad (3.9)$$

In the experiments the Universal Portfolios update mixture rule is used. The agent mixtures will need to be re-normalised. Similar to having absolute portfolios and active portfolios, the agents can also be absolute or active. In the case of absolute agents it is required that  $\sum_n q_n = 1$  and all  $q_n \geq 0$ , the normalisation is as follows:

$$q_{n,t+1} = \frac{q_{n,t+1}}{\sum_n q_{n,t+1}}. \quad (3.10)$$

In the case of active agents it is required that  $\sum_n q_n = 0$  and that  $\sum_n |q_n| = 1$ , the normalisation is as follows:

$$q_{n,t+1} = \frac{q_{n,t+1} - \frac{1}{N} \sum_n q_{n,t+1}}{\sum_n |q_{n,t+1} - \frac{1}{N} \sum_n q_{n,t+1}|} \quad (3.11)$$

The Online-Learning Algorithm then returns the updated portfolio controls  $b_{m,t}$ , the past agent wealth  $S_{n,t-1}$  and the past portfolio wealth  $S_{t-1}$ .

---

**Algorithm 1** Online-Learning Algorithm (OLA)

---

**Require:**

1. updated agent-controls  $\mathbf{H}_{n,t+1}$
2. current feature realisation  $\mathbf{x}_t$
3. current portfolio controls  $\mathbf{b}_t$
4. current agent-controls  $\mathbf{H}_{n,t}$
5. past agent-wealth  $S_{n,t-1}$
6. past portfolio wealth  $S_{t-1}$

**for**  $t$ -state **do**

Step 1: The portfolio wealth is updated

$$S_t = S_{t-1}(\mathbf{b}_t(\mathbf{x}_t^T - 1) + 1)$$

Step 2: The agent wealth is updated

$$S_{n,t} = S_{n,t-1}(\mathbf{H}_{n,t}(\mathbf{x}_t^T - 1) + 1)$$

Step 3: The agent mixture is updated for rule  $g$

$$q_{n,t+1} = g(q_{n,t}, S_{n,t})$$

Step 4: The agent mixtures are re-normalised

$$q_{n,t+1} = \begin{cases} \sum_n q_{n,t+1} = 1, q_{n,t+1} \geq 0 \\ \sum_n |q_{n,t+1}| = 1, \sum_n q_{n,t+1} = 0. \end{cases}$$

Step 5: The portfolio controls are updated

$$\mathbf{b}_{t+1} = \sum_n q_{n,t+1} \mathbf{H}_{n,t+1}$$

Leverage corrections

**if**  $(\nu = \sum_m |b_{m,t}|) \neq 1$  **then**

renormalise controls

$$\mathbf{b}_{n,t+1} = \frac{1}{\nu} \mathbf{b}_{n,t+1}$$

renormalise mixtures

$$q_{n,t+1} = \frac{1}{\nu} q_{n,t+1}$$

**end if**

**end for**

**return**  $(\mathbf{b}_{t+1}, S_{n,t}, S_t, q_{n,t+1})$

---

The agent controls are determined using algorithm 2 and algorithm 3. The Pattern Matching Algorithm is used to iterate over the agents and returns the agent controls of each of the agents by calling on the Matching Algorithm.

There are a total number of  $N$  agents and each agent is represented by parameters  $k, \ell, w$  and  $\tau$ . The parameter  $k$  is used to determine the window length of the agent, the parameter  $\ell$  is used to determine the amount of matching times of the agent, the parameter  $w$  is used to represent the stock cluster and the parameter  $\tau$  is used to represent the horizon parameter. There is a total of  $K$  values of  $k$ ,  $L$  values of  $\ell$ ,  $W$  values of  $w$  and  $\tau_n$  values of  $\tau$ . The total number of agents is  $N = \tau_n W K L$ , however in this dissertation only the default choice of  $\tau_n = 1$  is used in the experiments.

---

**Algorithm 2** PATTERN-MATCHING Algorithm (PMA)

---

**Require:**

1. features  $\mathbf{x}_t$
2.  $n$ -agent parameters  $k, \ell, s(n), \tau$
3. partitions  $\{p_\ell\}$

**for**  $n$ -agents **do**

$$\mathbf{H}_{n,t+1} = \text{MATCHING}(\tau, \{p_\ell\}, \{\mathbf{x}_{t-k}^t\}_{s(n)}, \{\mathbf{x}_t\}_{(p_\ell, s(n))})$$

**end for** agents

**return**  $\mathbf{H}_{t+1}$

---

The Matching Algorithm contains the actual process of finding matches in the history of the price relative data and calculating the covariance,  $\Sigma$ , and mean,  $\mu$ , of the matches (see Section 3.3) to update the controls using equation 3.23.

## 3.2 Portfolio Selection

A derivation of a quadratic approximation for determining the portfolio controls, as outlined in [18], will now be presented.

Algoet and Cover [6] shows that if a market is stationary ergodic, a log-optimal strategy is the best choice of strategy over the long term. The log optimal portfolio selection problem is given by:

$$\mathbf{b}^*(X_1^{t-1}) = \arg \max_{\mathbf{b}} \mathbb{E} [\log(\mathbf{b}(X_1^{t-1})\mathbf{X}_t) | \mathbf{X}_1^{t-1}]. \quad (3.12)$$

Where  $\mathbf{X}_t$  denotes the random expectation return vector given some past  $\mathbf{X}_1^{t-1}$  and  $\mathbf{b}^*$  denotes the log optimal portfolio.

Györfi *et al* [23] shows the semi-log-optimal strategies and log-optimal strategies have the same performance when tested on NYSE data. The semi-log-optimal portfolio takes on the following form:

$$\mathbf{b}^*(X_1^{t-1}) = \arg \max_{\mathbf{b}} \mathbb{E} [h(\mathbf{b}(X_1^{t-1})\mathbf{X}_t) | \mathbf{X}_1^{t-1}]. \quad (3.13)$$

We can consider the semi-log-optimal portfolio optimisation problem [45, 31]

$$\max_{\boldsymbol{\omega}} \{ \boldsymbol{\omega}^T \boldsymbol{\mu} - \frac{\gamma}{2} \boldsymbol{\omega}^T \Sigma \boldsymbol{\omega} \} \quad \text{s.t.} \quad \boldsymbol{\omega}^T \mathbf{1} = 1 \quad (3.14)$$

the following notation changes have been made:

1. The return expectation vector is denoted by  $\boldsymbol{\mu}$ .
2.  $\Sigma$  denotes the asset return covariance matrix.

3. The portfolio control vector is denoted by  $\omega$ .
4.  $\gamma$  denotes the risk aversion parameter.

Equation (3.14) can be rewritten as the mutual-fund Lagrangian

$$L = \omega^T \boldsymbol{\mu} - \frac{\gamma}{2} \omega^T \Sigma \omega - \lambda_\omega (\omega^T \mathbf{1} - 1) \quad (3.15)$$

and can be solved by using Kuhn-Tucker Methods. Equation (3.15) leads to the following two equations:

$$\omega^* = \frac{1}{\gamma} \Sigma^{-1} (\boldsymbol{\mu} - \lambda_\omega \mathbf{1}) \quad (3.16)$$

$$\omega^{*T} \mathbf{1} = 1. \quad (3.17)$$

We can use (3.16) and (3.17) to find the Lagrange multiplier:

$$\lambda_\omega = \frac{\mathbf{1}^T \Sigma^{-1} \boldsymbol{\mu}}{\mathbf{1}^T \Sigma^{-1} \mathbf{1}} - \frac{\gamma}{\mathbf{1}^T \Sigma^{-1} \mathbf{1}}. \quad (3.18)$$

We can substitute (3.18) into (3.16) to find a formulation of the mutual fund separation theorem:

$$\omega^* = \frac{\Sigma^{-1} \mathbf{1}}{\mathbf{1}^T \Sigma^{-1} \mathbf{1}} + \frac{1}{\gamma} \Sigma^{-1} \left( \boldsymbol{\mu} - \mathbf{1} \frac{\mathbf{1}^T \Sigma^{-1} \boldsymbol{\mu}}{\mathbf{1}^T \Sigma^{-1} \mathbf{1}} \right). \quad (3.19)$$

Equation (3.19) is a form of the active fund separation theorem and can be rewritten as :

$$\omega^* = \omega_B + \omega_A \quad (3.20)$$

where

$$\omega_B = \frac{\Sigma^{-1} \mathbf{1}}{\mathbf{1}^T \Sigma^{-1} \mathbf{1}} \quad (3.21)$$

$$\omega_A = \frac{\Sigma^{-1}}{\gamma} \left( \frac{\boldsymbol{\mu} \mathbf{1}^T - \mathbf{1} \boldsymbol{\mu}^T}{\mathbf{1}^T \Sigma^{-1} \mathbf{1}} \right) \Sigma^{-1} \mathbf{1} \quad (3.22)$$

The equations for  $\omega_A$  and  $\omega_B$  is used directly in the agent generating algorithms.  $\boldsymbol{\mu}$  denotes the mean of the portfolio return vector and  $\Sigma$  denotes the covariance matrix. The agent controls can now be calculated for either absolute or active agents as follows:

$$\mathbf{H}_{n,t} = \begin{cases} \mathbf{h}^T \mathbf{1} = 1, \mathbf{h} = \omega_B(\Sigma) + \omega_A(\gamma, \boldsymbol{\mu}, \Sigma) \text{ s.t. } \mathbf{h} \geq 0 \\ \mathbf{h}^T \mathbf{1} = 0, \mathbf{h} = \omega_A(\gamma, \boldsymbol{\mu}, \Sigma) \text{ s.t. } \sum |\mathbf{h}| = 1 \Leftrightarrow |\mathbf{h}|^T \mathbf{1} = 1 \end{cases} \quad (3.23)$$

### 3.3 Pattern Matching

The pattern matching part of the algorithm involves each agent searching through the entire history for matching times. A time  $t$  in the history is a match depending on the  $k$  and  $\ell$  terms of the agent.  $k$  is the window length of the agent that determines how many time periods in the window.  $\ell$  is used to determine how many matches each agent should use, this is denoted by  $\hat{\ell}$ . The following choices of  $\hat{\ell}$  have been investigated in this dissertation:

1. *Trivial*

$$\hat{\ell} = \ell \quad (3.24)$$

2. *Györfi et al Nearest Neighbour* [21] based where  $\hat{\ell}$  is determined by a variable  $p_\ell \in (0, 1)$ . The choice of  $p_\ell$  used in this dissertation is the same choice used in [21].

$$p_\ell = 0.02 + 0.5 \frac{\ell - 1}{L - 1} \quad (3.25)$$

$$\hat{\ell} = \lfloor p_\ell t \rfloor \quad (3.26)$$

The agent thus uses the closest  $\hat{\ell}$  matching times. In the event of a tie, the agent will use the older matching time only for the trivial case and the agent will use all matching times of the ties for the *Györfi et al Nearest Neighbour* [21] based case.

The matching criteria used in this dissertation is the Euclidean norm or Euclidean distance between two time periods formally defined as follows:

$$\|\mathbf{x}_{t-k}^{t-1} - \mathbf{x}_{T-k}^{T-1}\| \quad (3.27)$$

Where  $T$  represents the time that the agents are going to invest into,  $t$  represents times from the past and  $\mathbf{x}_{t-k}^{t-1}$  represents a sequence of price relative return vectors for  $k$  consecutive time periods.

The set of matching times can be formally defined as:

$$J = \{t | t \text{ is amongst the } \hat{\ell} \text{ minimum values of } \|\mathbf{x}_{t-k}^{t-1} - \mathbf{x}_{T-k}^{T-1}\|\} \quad (3.28)$$

$\hat{\mathbf{x}}$  can be defined as a sequence of the price relative vectors at the matching times in set  $J$ . The mean and covariance of  $\hat{\mathbf{x}}$  is used in equation 3.23 to calculate the agent controls.

### 3.4 Partitioning

The algorithm in this dissertation takes into account the possibility of partitioning the history. As discussed in section 3.3, each agent is required to search for a total of  $\hat{\ell}$  matching times. One option,

the trivial option, is to have each agent search the entire history for the best  $\hat{\ell}$  matching times. An alternate approach could be to partition the history into  $\hat{\ell}$  partitions and have each agent search for the best match in each partition to get a total of  $\hat{\ell}$  matching times. The choice of partition can be chosen with the intention of decreasing the computational similar to Györfi's first neighbour algorithm [21]. The partitioning may also be chosen with the intention of increasing the wealth of the portfolio, this could be based on side information or giving preference to matches that are more recent. The following are possible methods of partitioning the data:

1. Trivial Partitioning: Using the entire history

$$\{p_t\}_1 = \{(1, \dots, 1, 1, 1)\}. \quad (3.29)$$

2. Over-lapping Partitioning

$$\{p_t\}_T = \left\{ \begin{array}{c} (0, \dots, 0, 0, 1) \\ (0, \dots, 0, 1, 1) \\ (0, \dots, 1, 1, 1) \\ \vdots \\ (1, \dots, 1, 1, 1) \end{array} \right\}. \quad (3.30)$$

3. Exclusive Partitioning

$$\{p_t\}_T = \left\{ \begin{array}{c} (0, \dots, 0, 0, 1) \\ (0, \dots, 0, 1, 0) \\ (0, \dots, 1, 0, 0) \\ \vdots \\ (1, \dots, 0, 0, 0) \end{array} \right\}. \quad (3.31)$$

4. Side-Information Partitioning

$$\{p_t\}_T = \left\{ \begin{array}{c} (0, 0, 0, \dots, 0, 0, 1, 1) \\ (0, 0, 0, \dots, 1, 1, 0, 0) \\ \vdots \\ (0, 1, 0, \dots, 0, 0, 0, 0) \\ (1, 1, 1, \dots, 0, 0, 0, 0) \end{array} \right\}. \quad (3.32)$$

The partitions used for side-information partitioning can be based on observations made on the data or could be chosen to favour certain days of the week.

While various possible methods of partitioning the data is discussed in this dissertation, only the trivial method of partitioning the data is used in the experiments.

### 3.5 Clustering

As discussed in section 3.4, partitioning refers to when the data that an agent searches is dependent on time. Clustering is when the data that an agent searches is based on the selection of stocks.

Each cluster has an index of  $w$  and there are a total of  $W$  clusters. The choice of clusters used in the experiments is on classifying the stocks.

# Chapter 4

## Data

### 4.1 Synthetic Data

The algorithm was tested on four synthetic data cases (SDC) for both active and absolute portfolios. The synthetic data was generated for 10 stocks over 1000 time periods. The price relatives  $x_{m,t}$  for each stock at each time period was randomly generated from a lognormal distribution (`lognrnd` function in MATLAB generated using the Mersenne Twister pseudorandom number generator [38] and initialised using a specific seed value), each synthetic data case defines a mean,  $\mu$ , and variance,  $v$ , used to generate the dataset. The mean,  $\bar{\mu}$ , and standard deviation,  $\bar{\sigma}$ , of the associated normal distribution is given by :

$$\bar{\mu} = \log \left( \frac{\mu^2}{\sqrt{v + \mu^2}} \right) \quad (4.1)$$

$$\bar{\sigma} = \sqrt{\log \left( \frac{v}{\mu^2} + 1 \right)} \quad (4.2)$$

Table 4.1 summarises the four synthetic data cases, each case was generated 30 times and initialised with seed values 1, 2, . . . , 30 respectively.

#### 4.1.1 Synthetic Data Case 1 (SDC 1)

Synthetic Data Case 1 (SDC 1) was generated from a lognormal distribution with a mean price relative,  $\mu = 1$ , and a variance,  $v = 0.0002$ , to simulate a stock market where there is no significant increase or decrease in the value of a stock over time.

The expected outcome is that neither the active portfolio nor the absolute portfolio will be able to learn which stocks it should hold a long position or short position.

### 4.1.2 Synthetic Data Case 2 (SDC 2)

Synthetic Data Case 2 (SDC 2) was generated from a lognormal distribution with a mean price relative,  $\mu = 1.001$ , and a variance,  $v = 0.0002$ , to simulate a stock market where the value of the stocks are increasing over time.

The expected outcome is that the absolute portfolio will learn which stocks to hold a long position on, however the active portfolio will not be able to learn which stocks to hold a short position on as no stocks decrease in value over time.

### 4.1.3 Synthetic Data Case 3 (SDC 3)

Synthetic Data Case 3 (SDC 3) was generated from a lognormal distribution with a random mean price relative,  $\mu \geq 1$ , assigned to each stock and a variance,  $v = 0.0002$ . The random means is calculated as follows:

$$\mu_m = 1 + \max[0, \min(0.0005 + 0.0005\delta, 0.001)] \quad (4.3)$$

where  $\delta$  is a random number generated from a standard normal distribution (using the `randn` function in MATLAB with the Mersenne Twister pseudorandom number generator [38] and initialised using a specific seed value). This simulates a stock market where some stocks are increasing in value and some stocks are decreasing in value over time.

The expected outcome is that both the active portfolio and the absolute portfolio will learn to hold a long position on the stocks increasing in value over time and hold a short position on the stocks decreasing in value over time, however it is expected that the absolute portfolio will beat the active portfolio due to the growth rate of the stocks increasing in value over time.

### 4.1.4 Synthetic Data Case 4 (SDC 4)

Synthetic Data Case 4 (SDC 4) was generated from a lognormal distribution with mixed means assigned to the price relatives,  $\mu = 0.999$  was assigned to 3 stocks and  $\mu = 1.001$  was assigned to the remaining stocks, and a variance,  $v = 0.0002$ . This dataset simulates a stock market where the value of some stocks are increasing and the value of some stocks are decreasing.

The expected outcome is that both the active portfolio and the absolute portfolio will learn to hold a long position on the stocks increasing in value over time and hold a short position on the stocks

decreasing in value over time.

**Summary of Random Datasets**

<b>Dataset</b>	$\mu$	$v$
SDC 1	1	0.0002
SDC 2	1.001	0.0002
SDC 3	random $\geq 1$	0.0002
SDC 4	mixed	0.0002

Table 4.1: The means and variances that were chosen when generating the synthetic data sets. The random means for SDC 3 was calculated using Eqn. (4.3) and the means for SDC 4 was generated as described in section 4.1.4.

## 4.2 Real Data

The algorithm is tested on four sets of real data, summarised in Table 4.3, two data sets from the New York Stock Exchange (NYSE) obtained at [19] and two data sets from the Johannesburg Stock Exchange (JSE) obtained at [47].

### 4.2.1 NYSE Data

The NYSE dataset, as described in [19], comes from Yoram Singer and contains *close-to-close* price relatives for 36 stocks listed on the New York Stock Exchange from 1962-1984. This is the same data set used by Györfi *et al* in [20, 21] and Cover in [10].

### 4.2.2 NYSE Merged Data

The NYSE Merged dataset, as described in [19], was obtained from Yahoo! Finance and was cleaned and prepared by Gábor Gelencsér. This dataset contains *close-to-close* price relatives data for 23 stocks listed on the New York Stock Exchange from 1962-2006. The data of the 23 stocks during 1962-1984 is identical to the data described in section 4.2.1.

Date	Price Relative
1964-12-09	0.9979
1964-12-10	1.0046
1964-12-11	1.0104
1964-12-14	0.9946
1964-12-15	0.9991
1964-12-16	1.0009
1964-12-17	1.0049
1964-12-18	1.0048
1964-12-21	1.0000

Figure 4.1: A sample of the NYSE data for stock IBM. The data is in comma separated value (.csv) files, the first value is the date and the second value is the price relative of the stock.

### 4.2.3 JSE OHLC Data

The JSE OHLC dataset was obtained from Thomson Reuters Tick History (TRTH) [47] and contains daily data for 42 stocks listed on the Johannesburg Stock Exchange (JSE) from 1995-2015, however not all of the 42 stocks were listed in 1995 and the data for these stocks begins at a later time. The data lists the open, high, low and close prices for all of the 42 stocks, as shown in figure 4.2.

#RIC	Date[L]	Time[L]	Type	Qualifiers	Open	High	Low	Last	Volume	Open	Inte	Settle	ISIN Code	Data Source

ANGJ.J	20-Oct-98		End Of Day		29000	29300	28700	29300	149855					Verified

Figure 4.2: A sample of the original JSE OHLC data.(Screenshot from Microsoft Excel).

The raw data was processed into four datasets:

1. *close-to-close*:

The price relative for the  $m$ -th asset is calculated using the closing price and calculated as follows:

$$x_{m,t} = \frac{c_{m,t}}{c_{m,t-1}}. \quad (4.4)$$

where  $x_{m,t}$  represents the price relative and  $c_{m,t}$  represents the closing price at time  $t$ .

2. *open-to-close:*

The price relative for the  $m$ -th asset is calculated using the open price and closing price of the asset from the same trading period and is calculated as follows:

$$x_{m,t} = \frac{c_{m,t}}{o_{m,t}}. \quad (4.5)$$

where  $x_{m,t}$  represents the price relative,  $c_{m,t}$  represents the closing price at time  $t$  and  $o_{m,t}$  represents the opening price at time  $t$ .

3. *close-to-open:*

The price relative for the  $m$ -th asset is calculated using the opening price of the current trading period( $t$ ) and the closing price from the previous trading period ( $t - 1$ ) and is calculated as follows:

$$x_{m,t} = \frac{o_{m,t}}{c_{m,t-1}}. \quad (4.6)$$

where  $x_{m,t}$  represents the price relative,  $c_{m,t}$  represents the closing price at time  $t$  and  $o_{m,t}$  represents the opening price at time  $t$ .

4. *open-to-open:*

The price relative for the  $m$ -th asset is calculated using the opening price and calculated as follows:

$$x_{m,t} = \frac{o_{m,t}}{o_{m,t-1}}. \quad (4.7)$$

where  $x_{m,t}$  represents the price relative and  $o_{m,t}$  represents the opening price at time  $t$ .

Splits, mergers and missing data<sup>1</sup> were handled by assigning a price relative of 1 for that day.

Date	Price Relative
1998-09-01	1.01235
1998-09-02	1.03659
1998-09-03	1.01059
1998-09-04	1.05471
1998-09-07	1.04305
1998-09-08	1.01587
1998-09-09	0.95833
1998-09-10	1.01196
1998-09-11	0.99356

Figure 4.3: A sample of the processed JSE OHLC data to *close-to-close* price relatives for Anglo American PLC (AGLJ.J). The data is stored in Microsoft Excel (.xls) files, the first value is the date and the second value is the price relative of the stock.

<sup>1</sup> Splits and mergers were identified as having a  $x_{m,t} < 0.7$  and  $x_{m,t} > 1.3$  respectively.

#### 4.2.4 JSE Intraday Data

The JSE Intraday dataset was obtained from Thomson Reuters Tick History (TRTH) [47], in a comma-separated values (CSV) file, and consists of high frequency data for 40 stocks listed on the Johannesburg Stock Exchange (JSE) during 2013. The file contains the following fields:

Field	Description
RIC	Reuters Instrument Price
Date[L]	Date of order book event
Time[L]	time (in microseconds) of order book event
Type	Type of LOB event ( <i>Trade</i> , <i>Auction</i> or <i>Quote</i> )
Price	The volume of the trade or auction
Volume	The price at which the trade or auction was executed
Market VWAP	Traded volume weighted average price (VWAP) of the share
Bid Price	level 1 bid price
Bid Size	level 1 bid size
Ask Price	level 1 ask price
Ask Size	level 1 ask volume

Table 4.2: Description of the fields available in the CSV file.

The CSV file was split into weekly data per RIC by the QuERI Lab team<sup>2</sup> and saved as MAT-Files. The high frequency data was converted into 5 minute bar data using the trade price. The 5 minute barred data starts at 9h30 and ends at 16h30 for normal trading days and starts at 9h30 and ends at 11h30 for early close days. The 5 minute bar data was then converted into price relative data for each stock and saved as MAT-Files.

#### Summary of Real Datasets

Data Set	Time Period	Stocks
NYSE [19]	1962-1984	36
NYSE Merged [19]	1962-2005	23
JSE OHLC [47]	1995-2015	42
JSE Intraday [47]	2013	40

Table 4.3: Description of the real data sets that the algorithm was tested on.

<sup>2</sup>Quantifying Emergence, Risk and Information. The data was prepared by Dieter Hendricks and Michael Harvey.

# Chapter 5

## Results

### 5.1 Implementation

#### 5.1.1 Parameters Chosen

In all experiments the following parameters were used:

- i.  $k = (1, 2, \dots, 5)$  which implies that  $K = 5$
- ii.  $\ell = (1, 2, \dots, 10)$  which implies that  $L = 10$
- iii.  $w = 1$  for all experiments with the exception of the clustered results where  $w = 3$ . This implies that  $W = 1$  for experiments with the trivial choice of clusters and  $W = 3$  for the experiments that include clusters.
- iv.  $\tau_n = 1$
- v. The pattern matching used is formulated in equations 3.25 and 3.26

This implies that the number of agents,  $N = \tau_n W K L$ , is 50 when the trivial choice of clusters ( $W = 1$ ) are used and 150 for the experiments that include clusters ( $W = 3$ ).

#### 5.1.2 Comparison to Results from the Literature

As a measure of performance of the algorithm, the results are compared to Györfi *et al*'s nearest neighbour method [21, 22] and Thomas Cover's Universal Portfolio method [10]. It can be observed that if the algorithm described in this dissertation were to replace the analytic solution with an optimisation step for the absolute case, the algorithm would be analogous to Györfi's Nearest Neighbour

method [21, 22]. The pattern class, as described in section 5.1.4, therefore implements a recovered version of the Nearest Neighbour algorithm in this manner, using `fmincon` for the optimisation, as to allow for accurate comparisons of the computational running times. A MATLAB function implementing Thomas Cover’s Universal Portfolio method [10] was created and recovered the exact results obtained in [10].

Results obtained from the algorithm presented in this dissertation that compare favourably to the results obtained from the methods presented in the literature and benchmarks such as the best stock would indicate that the algorithm has successfully exploited patterns in the time series data.

### 5.1.3 Implementation Process

Figure 5.1 outlines the process followed to conduct the experiments. Step 2 of the process checks for gaps in the data and inaccuracies caused by splits and mergers and replaces these values with a price relative of one.

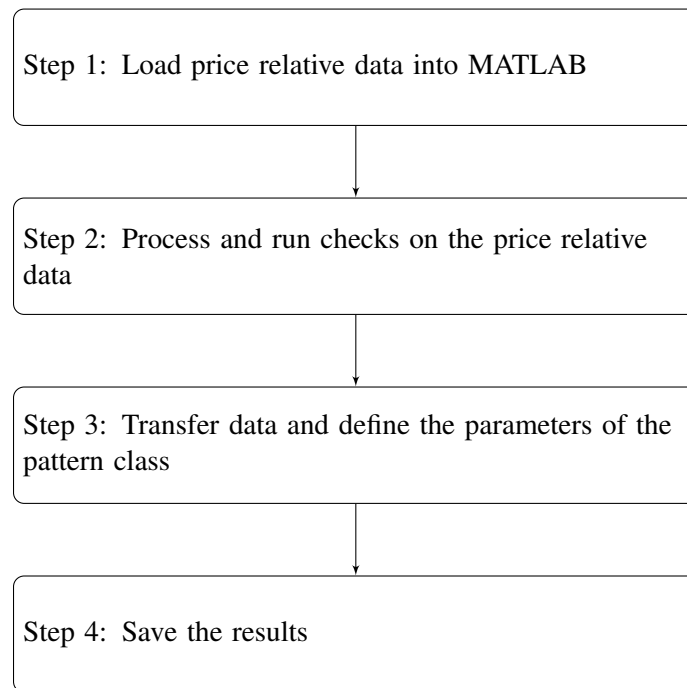

Figure 5.1: A process flow diagram illustrating the steps that have been followed in generating the results.

### 5.1.4 Pattern Class

A MATLAB class named *pattern* (see Appendix A.1) was created to implement the algorithms 1, 2 and 3. The class contains the following properties:

Property	Description
$x$	The price relative data
$k$	A list of the $k$ values
$\ell$	A list of the $\ell$ values
$c$	A tuple describing the clusters
$NTYPE$	The portfolio type ( <i>active</i> , <i>absolute</i> or <i>gyorfi_opt</i> )
$b$	The portfolio controls
$S$	The portfolio wealth
$h$	The agent controls
$SH$	The agent wealth

Table 5.1: A summary of the properties contained in the pattern class.

The class contains the following methods:

Function	Description
pattern	The constructor of the pattern class
offline	Offline estimation of the wealth $S$ and portfolio controls $SH$
online	Online estimation of the wealth $S$ and portfolio controls $SH$
learn	Updates the agent controls $h$ , the portfolio controls $b$ and the wealth $S$
partition	Partitions the data
quadbet	Solves the quadratic approximation (Equation 3.23)
match	Implements the pattern matching

Table 5.2: A summary of the Methods contained in the pattern class.

## 5.2 Synthetic Data

Experiments were run for both the absolute and active portfolios on all four synthetic data sets. Each data set depicts a different behavioural characteristic of a market, as described in section 4.1. Table 5.3 shows the best wealth achieved from all of the 30 runs per dataset as well as the average wealth achieved from all of the 30 runs per dataset.

### 5.2.1 Wealth Achieved from Synthetic Datasets

Wealth Gained ( $S$ ) from Investing in Synthetic Data

Data	Port.	Wealth		Best Agent	
		Best	Avg.	Best	Avg.
SDC 1	Abs.	1.2315	0.9917	1.8063	1.2505
	Act.	1.4507	1.0516	1.7532	1.3579
SDC 2	Abs.	3.2410	2.6119	4.6545	3.2696
	Act.	1.4508	1.0516	1.7532	1.3583
SDC 3	Abs.	2.3202	1.6850	3.0908	2.0899
	Act.	1.4901	1.1709	1.7816	1.4508
SDC 4	Abs.	2.4554	1.8964	2.9307	2.2501
	Act.	2.9275	2.0554	3.2698	2.2975

Table 5.3: Wealth achieved by the active and absolute portfolios for 30 runs of each synthetic data case.

### 5.2.2 Kolmogorov-Smirnov Tests

Two-sample Kolmogorov-Smirnov tests were run on the datasets because it is a non-parametric test and makes no assumption about the distribution of the datasets. The following notation is used:

1.  $S_1$  refers to the total wealth gained from the portfolio.
2.  $S_2$  refers to the wealth gained from the best agent of the portfolio.
3.  $S_3$  refers to the wealth gained from the best stock.

The following combinations of two-sample Kolmogorov-Smirnov were performed:

1.  $S_2 > S_1$  : The alternative hypothesis that the cumulative distribution function (CDF) of the wealth gained from the best agent of the portfolio,  $S_2$ , is larger than the CDF of the total wealth gained from the portfolio,  $S_1$ , at the 5% significance level.
2.  $S_2 > S_3$  : The alternative hypothesis that the CDF of the wealth gained from the best agent of the portfolio,  $S_2$ , is larger than the CDF of the wealth gained from the best stock,  $S_3$ , at the 5% significance level.
3.  $S_3 > S_1$  : The alternative hypothesis that the CDF of the wealth gained from the best stock,  $S_3$ , is larger than the CDF of the total wealth gained from the portfolio,  $S_1$ , at the 5% significance level.

### Comparison of Average $p$ Values of Wealth Gained ( $S$ ) from the Active Portfolio

	Best Agent vs. Total Wealth		Best Agent vs. Best Stock		Best Stock vs. Total Wealth	
Hyp.	$S_2 > S_1$		$S_2 > S_3$		$S_3 > S_1$	
	$\bar{p}$	$p > \bar{p}$	$\bar{p}$	$p > \bar{p}$	$\bar{p}$	$p > \bar{p}$
SDC 1	0.8085	0.1719	0.0310	0.0000	0.6540	0.0129
SDC 2	0.8087	0.1719	0.0000	0.0000	0.8731	0.4072
SDC 3	0.8304	0.1719	0.0000	0.0000	0.9044	0.5627
SDC 4	0.7254	0.0129	0.0000	0.0000	0.6218	0.0057

Table 5.4: Comparisons of the average  $p$  values of the wealth gained from the active portfolio. The first  $p$  value in each column is average  $p$  value, of the 30 data sets for each case, using two-sample Kolmogorov-Smirnov tests for the alternative hypotheses (Hyp.). The second  $p$  value is obtained from the two-sample Kolmogorov-Smirnov tests for the alternative hypothesis that the cumulative distribution function (CDF) of the  $p$  values for the 30 data sets for each case is larger than the CDF of the average  $p$  value at the 5% significance level.

### Comparison of Average $p$ Values of Wealth Gained ( $S$ ) from the Absolute Portfolio

	Best Agent vs. Total Wealth		Best Agent vs. Best Stock		Best Stock vs. Total Wealth	
Hyp.	$S_2 > S_1$		$S_2 > S_3$		$S_3 > S_1$	
	$\bar{p}$	$p > \bar{p}$	$\bar{p}$	$p > \bar{p}$	$\bar{p}$	$p > \bar{p}$
SDC 1	0.8931	0.4072	0.0002	0.0000	0.6469	0.0129
SDC 2	0.6424	0.0129	0.0000	0.0000	0.5672	0.0009
SDC 3	0.5933	0.0023	0.0004	0.0000	0.7949	0.1003
SDC 4	0.8457	0.2742	0.0000	0.0000	0.6441	0.0057

Table 5.5: Comparisons of the average  $p$  values of the wealth gained from the absolute portfolio. The first  $p$  value in each column is average  $p$  value, of the 30 data sets for each case, using two-sample Kolmogorov-Smirnov tests for the alternative hypotheses (Hyp.). The second  $p$  value is obtained from the two-sample Kolmogorov-Smirnov tests for the alternative hypothesis that the cumulative distribution function (CDF) of the  $p$  values for the 30 data sets for each case is larger than the CDF of the average  $p$  value at the 5% significance level.

Two-sample Kolmogorov-Smirnov tests were also used to compare the wealth achieved from one of the synthetic data cases against the wealth achieved from the other three synthetic data cases per seed value as shown in tables 5.6 and 5.7. As expected, the results show that the active portfolio performs the best on SDC 4 as this dataset includes stocks that are decreasing in value over time and the absolute portfolio performs the best on SDC 2 as this dataset contains the most stocks that are increasing in value over time.

**Comparison of  $p$  Values of Wealth Gained ( $S$ ) from the Active Portfolio**

	<b>SDC 1</b>	<b>SDC 2</b>	<b>SDC 3</b>	<b>SDC 4</b>

<b>SDC 3</b>	1.0000	0	-	0.1289
<b>SDC 4</b>	1.0000	0	0.5055	-

Table 5.7: Comparison of the average  $p$  values from two-sample Kolmogorov-Smirnov tests for the alternative hypothesis that the cumulative distribution function (CDF) of wealth gained from the absolute portfolio on SDC  $i$  is larger than the CDF of wealth gained from the active portfolio on SDC  $j$  at the 5% significance level, where  $i$  represents the rows and  $j$  represents the columns of the table. The  $p$  values is the average of 30 comparisons, each comparison using a seed value of 1, 2, . . . , 30 respectively.

### 5.3 NYSE Data

Experiments were run on the same two stock combinations used by Thomas Cover [10] and Györfi *et al* [20, 21, 22] for both the absolute and active portfolios. The results of the wealth achieved from the active portfolio and the absolute portfolio are compared to the wealth achieved from the implemented versions of the Györfi nearest neighbour algorithm [21] and the Universal Portfolio method [10]. As this is the same dataset used in [21] and [10], the results are compared to the actual results published in [21] and [10]. However, since the results from the Universal Portfolio method [10] was identically recovered it is only shown once in the results tables.

The experiments were carried out on the following stock combinations:

- i. Iroquois Brands Ltd. and Kin Ark Corp.
- ii. Commercial Metals and Mei Corp.

- iii. Commercial Metals and Kin Ark Corp.
- iv. IBM and Coca-Cola
- v. All 36 NYSE stocks

## 5.5 JSE Daily Data

Experiments were run for both the absolute and active portfolios on all four datasets (*close-to-close*, *open-to-close*, *close-to-open* and *open-to-open*) and the results compared to the wealth achieved from the implemented versions of the Györfi nearest neighbour algorithm [21] and the Universal Portfolio method [10].

The experiments were carried out on the following stock combinations:

- i. AngloGold Ashanti Ltd. (ANG) and Anglo American PLC (AGL)
- ii. Standard Bank Grp. Ltd. (SBK) and Firststrand Ltd. (FSR)
- iii. Tiger Brands Ltd. (TBS) and Woolworths Holdings (WHL)

## 5.6 JSE Intraday Data

Experiments were run for both the absolute and active portfolios and the results compared to the wealth achieved from the implemented versions of the Györfi nearest neighbour algorithm [21] and the Universal Portfolio method [10].

The experiments were carried out on the following stock combinations:

- i. Anglogold Ashanti Ltd. (ANG) and Anglo American PLC (AGL)
- ii. Standard Bank Grp. Ltd. (SBK) and Firststrand Ltd. (FSR)
- iii. Tiger Brands Ltd. (TBS) and Woolworths Holdings (WHL)
- iv. 10 JSE Stocks
- v. 20 JSE Stocks
- vi. 30 JSE Stocks
- vii. 20 JSE Stocks (with clusters)

### 5.6.1 ANG and AGL

# Chapter 6

## Conclusion

### 6.1 Overall Summary

In this dissertation, an algorithm for portfolio selection that allows for long only portfolios (absolute portfolios) and zero cost portfolios (active portfolios) is presented. The results obtained from both the active and absolute portfolios are compared with strategies from the literature, namely the Universal Portfolios strategy by Thomas Cover [10] and the Nearest Neighbour method by Györfi *et al* [21]. It can be argued that the algorithm is analogous to Györfi's nearest neighbour algorithm when using the same choice of neighbours Györfi uses in [21], a long only portfolio and an optimisation step instead of the analytical approach. However it is important to note that the algorithm presented potentially allows for the algorithm to be implemented online, as well as the inclusion of the ability to cluster the stocks and partition the time series.

While clustering has been investigated, only the trivial form of the partitioning has been investigated. The results obtained from using clusters in section 5.6.8 show that clustering the stocks into resources, financials and industrials can be advantageous.

It can be concluded from the results that there are patterns that exist in both the New York Stock Exchange and the Johannesburg Stock Exchange and these patterns can potentially be exploited. The results of the algorithm for both the absolute and active portfolios compares favourably with the strategies from the literature and in most cases can beat the best stock. The results from the two stock combinations show that the wealth achieved from the absolute portfolio has a slight variance to the results achieved from Györfi's nearest neighbour strategy, this indicates that the quadratic approximation is highly accurate in comparison to the optimisation. This claim is further supported by the figures that show the wealth achieved from the different strategies for the two stock combinations. As the number of stocks are increased, it can be observed that the accuracy of the quadratic approximation decreases as the number of stocks increase. This is illustrated perfectly in Chapter 5, sections 5.5 and 5.6, for the JSE data as the number of stocks chosen increase from two stock combinations to 10, 20 and 30. However the loss of accuracy is the cost of achieving better computational performance.

Another observation can be made on the JSE daily data results in section 5.5 that the choice of price relative data set can have a significant impact on the wealth achieved. For instance the resources two stock combination (ANGJ and AGLJ) perform the best on the *open-to-close* data set, the financials two stock combination (SBKJ and FSRJ) performs well on the *open-to-open* and *close-to-close* data set and the industrials two stock combination (TBSJ and WHLJ) performs the best on the *open-to-open* data set. All of the two stock combinations and multiple stock combinations perform poorly on the *close-to-open* data set in comparison to the other price relative data sets, this could most likely be linked to the fluctuations in stock prices caused overnight between the closing price and opening price.

One of the criticisms of the results in this dissertation could be that trading costs, market impacts and stock liquidity are not taken into account. To address the concerns relating to stock liquidity, in majority of the stock combinations for the Johannesburg Stock Exchange only highly liquid stocks have been selected. However, it should be kept in mind that the aim of this dissertation is to confirm the existence of time-series patterns in the financial market data investigated and not to find a profitable trading strategy, even though the existence of a profitable trading strategy is a key measure of the existence of non-trivial patterns that have not yet been arbitrated out of the system.

## 6.2 Further Work

Possible areas of further work on this topic can include investigating different methods of partitioning the time series data as mentioned in Chapter 3, investigating the pattern matching aspect of portfolio selection and an investigation on the use of parallel computing to significantly decrease the computational running time of the agents.

Another extension would be to make the algorithm truly online [15, 40]. This can be achieved by creating a library of the matches offline, including an update rule, and having the algorithm search the library for the closest match at each time iteration.

In this dissertation, there is no consideration made to performance measures other than the wealth gained of the portfolios. There are however more effective measures of algorithm performance that are an important aspect of testing online algorithms, such as the approach suggested by Mohr and Schmidt [40] based on average competitive performance. These issues are not directly addressed in this dissertation, however it is an important consideration to take into account once the algorithm becomes truly online.

# Appendix A

## MATLAB Code

### A.1 Pattern Class

The algorithms have been implemented using a MATLAB class called `pattern`<sup>1</sup>, as discussed in section 5.1.4. The first input parameter is the price relative data. Below is a guide on how to import and prepare the data for the pattern class.

```
%% Load data
stock1 = csvread('stock1.csv');
stock2 = csvread('stock2.csv');

% x is the return vector of the stocks
x = [stock1(:,2) stock2(:,2)];

% size of x
[m,n]=size(x);
% reshape x to [Stocks,Features,Times]
x = reshape(x',n,1,m);
```

The second input parameter is the  $k$  values and the third input parameter is the  $l$  values. The fourth parameter defines any clustering of the stocks and the fifth parameter states the portfolio strategy that should be used. See below for examples on how the method is run for the different portfolios.

#### 1. Active Portfolio

```
%% Active Porfolio

p = pattern(x,1:5,1:10);
```

#### 2. Absolute Portfolio

---

<sup>1</sup>The pattern code is available at <https://github.com/FayyazL/Pattern>

```

%% Absolute Portfolio

p = pattern(x,1:5,1:10,[],'absolute');

```

### 3. Györfi's Nearest Neighbour

```

%% Gyorfi Nearest Neighbour

p = pattern(x,1:5,1:10,[],'gyorfi_opt');

```

The above examples do not take into account running the code with clusters, below is an example of how to do so.

```

%% Clustered stocks
resources = [1 1 0 1 0 0 0 0 1 1 0 0 1 1 0 0 0 0 0 0];
industrials = [0 0 1 0 1 1 0 1 0 0 0 0 0 0 1 0 1 1 0 1];
financials = [0 0 0 0 0 0 1 0 0 0 1 1 0 0 0 1 0 0 1 0];
clusters = [resources; industrials; financials];
clusters = logical(clusters);

p = pattern(x,1:5,1:10,clusters);

```

The pattern class is shown below.

```

classdef pattern
    % PATTERN Pattern matching and learning class
    %
    % The class implements both online and offline pattern matching and
    % learning over k-tuples for M objects and N features as specified in
    % an MxNxP data matrix X. The algorithm searches for L nearest-neighbour
    % K-tuple matches in the provided partition of data. A quadratic
    % approximation is used to find the log-optimal portfolio using T+1
    % expected return subsequent to the pattern matching times T for each
    % k and ell to find H(K,L,CI;T) and SH(K,L,CI;T) for each K-tuple
    % L value and cluster CI. The controls are then aggregate using machine
    % learning to provide the controls B and realised accumulated
    % performance S. If the K matching patterns are predefined then K is
    % the index over the matching patterns. The default is and empty
    % matching pattern and to use the last k-tuple as the matching pattern.
    %

%% methods
methods
%% constructor
function p = pattern(varargin)
% P = PATTERN/PATTERN constructor
%
% P = PATTERN(X,K,ELL,CI,NTYPE,LNTYPE,LTYPE) For data X (price relatives)
% and is MxNxP dimensional data for M objects, N features and
% P date-times. dim(X) is dim(Price)-1. A typical object is
% a stocks, e.g. AGL, a typical feature is a factors such as
% OPEN, HIGH, LOW, CLOSE (OHLC), and date-times are the time
% stamps for the data.
%
% Example 1:
% >> x = 1+0.2*randn(10,1,1000);
% >> p = offline(p);
% >> p.S
%
% P = PATTERN(X,XNK,ELL,CI,NTYPE,LNTYPE,LTYPE) For matching
% pattern XNK instead of K-tuple range.
%
% P = PATTERN(X,XNK,ELL,CI,NTYPE,LNTYPE,LTYPE,TREND)
% LONGTERM is TRUE to use long-term relative views. This is
% by default false.
%
% The data X is homogenize in time. K is the set of tuple
% sizes if there is no matching pattern e.g. [1:3], if there
% is a matching pattern it is the number of matching patterns.
% The number of matching times is ELL this is typically 10
% per partition. The cluster definitions is CI, this is by
% default the trivial cluster (all the objects) when CI is
% empty. CI is KxM for K clusters of M objects. NTYPE is the
% strategy normalisation and can be either 'active', 'absolute'
% or 'gyorfi_opt'. LNTYPE is the agent normalisations and can
% be either 'active' or 'absolute'.
% The LTYPE is the learning type this is by default 'univ'.
%
% Note: X are price relatives (P(t)/P(t-1)). These can be
% conveniently computed using EXP(DIFF(LOG(P))).

        [zeros(1,m)';ones(1,m)'],ones(1,m),1,[],[],[],...
        optimset('Algorithm','sqp','Display','off'));
    hk1 = hk12';
end
end

```

## A.2 Universal Portfolios

The following MATLAB function was used to recover the results of Cover's Universal Portfolio [10] algorithm<sup>2</sup>. The function takes in the price relative data and returns the portfolio wealth, the wealth of the stocks and the fraction allocated to the first stock.

```
function [universalwealth, stock1wealth, stock2wealth, bm] = cover_up_rec(x)
% COVER_UP_REC - Implementation of Thomas M. Cover's Universal Portfolio
% for two stocks
%
% Syntax: [universalwealth, stock1wealth, stock2wealth, bm] = cover_up_rec(x)
%
% Inputs:
%   x - Price Relative Data of the two stocks
%
% Outputs:
%   universalwealth - Wealth acheived by the portfolio
%   stock1wealth - Wealth acheived by stock 1
%   stock2wealth - Wealth acheived by stock 2
%   bm - Fraction of wealth allocated to stock 1

%% STEP 1: Initialise Variables

[n, ~] = size(x);
stock1wealth=zeros(n,1);
stock2wealth=zeros(n,1);
universalwealth=zeros(n,1);
bm = zeros(n,1);
bm(1) = 0.5;

% Sn is the wealth accumulated from the constant rebalanced portfolios
Sn = zeros(n,21);

%% STEP 2 Update the Portfolio
for i = 1:n
    % Update the wealth of stock 1 and stock 2
    stock1wealth(i) = prod(x(1:i,1));
    stock2wealth(i) = prod(x(1:i,2));

    % Update the wealth achieved by the universal portfolio
    Sn(i,:) = (0:0.05:1)*x(i,1) + (1:-0.05:0)*x(i,2);
    universalwealth(i) = (sum(prod(Sn(1:i,:))))/21;

    % Update wealth assigned to stock 1
    if i >1
        b = sum((0:0.05:1)*(prod(Sn(1:i,:))')) / (sum(prod(Sn(1:i,:))));
        bm(i) = b;
    end
end
end
```

The function is called up as follows:

---

<sup>2</sup>The code is available at <https://github.com/FayyazL/Pattern>

```
%% Load data
stock1 = csvread('stock1.csv');
stock2 = csvread('stock2.csv');

% x is the return vector of the stocks
x = [stock1(:,2) stock2(:,2)];

[U_S, S1, S2, b] = cover_up_rec(x);
```
