Abstract: Blastocystis is a common and broadly distributed microbial eukaryote inhabiting the gut of humans and other animals. The genetic diversity of Blastocystis is extremely high comprising no less than 17 subtypes in mammals and birds. Nonetheless, little is known about the prevalence and distribution of Blastocystis subtypes colonising humans in Thailand. Molecular surveys of Blastocystis remain extremely limited and usually focus on the central, urban part of the country. To address this knowledge gap, we collected stool samples from a population of Thai adults (n=178) residing in Chiang Rai Province. The barcoding region of the small subunit ribosomal RNA was employed to screen for Blastocystis and identify the subtype. Forty-one stool samples (23%) were identified as Blastocystis positive. Six of the nine subtypes that colonise humans were detected with subtype (ST) three being the most common (68%), followed by ST1 (17%) and ST7 (7%). Comparison of subtype prevalence across Thailand using all publicly available sequences showed that subtype distribution differs among geographic regions in the country. ST1 was most commonly encountered in the central region of Thailand, while ST3 dominated in the more rural north and northeast regions. ST2 was absent in the northeast, while ST7 was not found in the center. Thus, this study shows that ST prevalence and distribution differs not only among countries, but also among geographic regions within a country. Potential explanations for these observations are discussed herewith.

Editorial Board,
Infection Genetics and Evolution

Dear Editors,

Here we submit a revised version of our manuscript entitled: “**High diversity of Blastocystis subtypes isolated from asymptomatic adults living in Chiang Rai, Thailand**”.

We have addressed all the comments from the reviewers and hope the manuscript is now suitable for publication.

The manuscript contains only original data that have not been submitted or published elsewhere. We look forward to hearing from you regarding our revised manuscript.

Sincerely,

Eleni Gentekaki, Ph.D.

We thank the reviewers for the positive comments on our manuscript. Below, we address the reviewers' points. Replies are in bold lettering.

Reviewer #1

I think the title is not fit to this manuscript, because the new data obtained in this study was limited from northern region of Thailand.

We have modified the title as follows: High diversity of *Blastocystis* subtypes isolated from asymptomatic adults living in Chiang Rai, Thailand

Line 51-:

Description in this sentence is incorrect, because there are many *Blastocystis* organisms had been identified in addition to 17 kinds of the STs.

We have added the following sentence to account for the lineages composed of reptilian, amphibian and insect sequences and which have not been assigned to subtypes. Lines 54-56: Isolates from avian and mammalian hosts are currently classified into 17 subtypes (STs) based on the divergence of the small subunit ribosomal RNA (SSU rRNA), though new STs might be arising (Alfellani et al., 2013c; Betts et al., 2018;). *Blastocystis* isolated from reptilian, amphibian and insect hosts are distinct and are not assigned into subtypes.

Lines 56-:

I think that ST9 is only isolated from humans.

We have added the following sentence in lines 59-60: The exception is ST9, which has yet to be found in a non-human host.

Line 153-:

I am confusing " the alignment contained 1,379 sites", because only barcode-region (ca. 600bp) was amplified by the nested-PCR for sequencing in this study.

Indeed, even though we amplified the barcode region, our alignment contained many full-length sequences (~1800bp). Thus, after trimming, the remaining sites were more than 600bp. This is standard practice in phylogenetics, whereby missing data is the norm. By doing this we improve resolution of the phylogenetic tree and strengthen support at the nodes. The topology of the tree remains unchanged. Many investigators do the same. For instance, Alfellani et al., 2013. Genetic diversity of *Blastocystis* in Livestock and zoo animals, also amplified the barcoding region, but their alignment contained 1,462 sites.

Discussion

I feel the discussion is too long for the results, please concise the discussion. Several parts may be deleted where doesn't match the purpose of this study (lines 83-).

Our discussion consists of four parts: 1) asymptomatic carriage of Blastocystis, 2) comparison of prevalence rates to other studies in Thailand, 3) subtypes detected in this study, and 4) subtype distribution in Thailand. We have shortened the discussion in parts three and four.

Reviewer #2

My only comment is that it is a small study sample number for the Chiang Rai study population and all are asymptomatic. This makes it difficult to know the true prevalence of Blastocystis in this region. Only using asymptomatic people means that you might be missing a large number of positives and potential different STs which may come from symptomatic people. This limitation should be stated in the discussion.

We agree with the reviewer's comment. The purpose of this pilot study was to examine which subtypes circulate in asymptomatic individuals. To that end, we have changed the title to reflect our study site and sampled population and we have also emphasized this in the discussion (Lines: 204-205, 270-271, 278-279).

KEY FINDINGS

- First study of Blastocystis prevalence and subtyping in Chiang Rai Province, Thailand
- Six of the nine subtypes known to colonize humans were found
- ST3 is the dominant ST followed by ST1 and ST7
- Distribution of Blastocystis subtypes among geographic regions of Thailand differs

22 **Abstract**

23

24 Blastocystis is a common and broadly distributed microbial eukaryote inhabiting the
25 gut of humans and other animals. The genetic diversity of Blastocystis is extremely
26 high comprising no less than 17 subtypes in mammals and birds. Nonetheless, little is
27 known about the prevalence and distribution of Blastocystis subtypes colonising
28 humans in Thailand. Molecular surveys of Blastocystis remain extremely limited and
29 usually focus on the central, urban part of the country. To address this knowledge gap,
30 we collected stool samples from a population of Thai adults (n=178) residing in
31 Chiang Rai Province. The barcoding region of the small subunit ribosomal RNA was
32 employed to screen for Blastocystis and identify the subtype. Forty-one stool samples
33 (23%) were identified as Blastocystis positive. Six of the nine subtypes that colonise
34 humans were detected with subtype (ST) three being the most common (68%),
35 followed by ST1 (17%) and ST7 (7%). Comparison of subtype prevalence across
36 Thailand using all publicly available sequences showed that subtype distribution
37 differs among geographic regions in the country. ST1 was most commonly
38 encountered in the central region of Thailand, while ST3 dominated in the more rural
39 north and northeast regions. ST2 was absent in the northeast, while ST7 was not
40 found in the center. Thus, this study shows that ST prevalence and distribution differs
41 not only among countries, but also among geographic regions within a country.
42 Potential explanations for these observations are discussed herewith.

43

45 **Keywords:** Blastocystis; genetic diversity; prevalence; subtyping; Thailand

46

47 **1. Introduction**

48

49 Blastocystis is the most commonly found protist in the gastrointestinal tract of
50 humans and other animals (Roberts et al., 2013; Tan, 2008). Though Blastocystis
51 exhibits morphological stasis, it has a high degree of genetic heterogeneity. Isolates
52 from avian and mammalian hosts are currently classified into 17 subtypes (STs) based
53 on the divergence of the small subunit ribosomal RNA (SSU rRNA), though new STs
54 might be arising (Alfellani et al., 2013c; Betts et al., 2018;). Blastocystis isolated from
55 reptilian, amphibian and insect hosts are distinct and are not assigned into subtypes.
56 So far, only ST1-ST9 have been found in humans with ST1-ST4 being the most
57 common colonisers (Alfellani et al., 2013b). However, these STs have also been
58 detected in a variety of non-human hosts, suggesting that Blastocystis has low host
59 specificity (Stensvold and Clark 2016). The exception is ST9, which has yet to be
60 found in a non-human host. The rest of the STs have so far been identified in both
61 domesticated and wildlife animal hosts (Alfellani et al., 2013a).

62 Lately, considerable research effort has gone into deciphering potential roles
63 of Blastocystis in intestinal disease. For instance, an association between presence of
64 Blastocystis and irritable bowel syndrome has been discussed frequently, though a
65 definitive causal link has yet to be postulated (Jimenez-Gonzalez et al., 2012;
66 Khademvatan et al., 2017; Poirer et al., 2012; Yakoob et al., 2010). Nonetheless,
67 emerging data have shown presence of Blastocystis in asymptomatic individuals
68 leading to the hypothesis that the organism is part of the healthy adult gut microbiota
69 and that only specific STs and/or genotypes might be pathogenic (Chabe et al., 2017;
70 Scanlan and Stensvold, 2013; Scanlan et al., 2014; Stensvold and van der Giezen,
71 2018). In this context, surveys examining prevalence of Blastocystis should ideally be

72 accompanied by subtyping. Thus, while the cosmopolitan status of Blastocystis is well
73 established, geographic distribution of specific subtypes and their prevalence are
74 relatively recent endeavors.

75 Research efforts on the latter two are disproportionate among countries and/or
76 geographic regions: a plethora of Blastocystis studies come from the Americas and
77 Europe, whilst Asia remains disproportionately sampled, given that half of the earth's
78 population resides in Asian countries (El Safadi et al., 2016; Scanlan et al., 2016;
79 Villegas-Gomez et al., 2016). Collectively, these studies have shown that ST3 is the
80 most prevalent one in almost all regions that have been examined, with a notable
81 exception (Oliveira-Arbex et al., 2018). Prevalence of the other common STs –
82 namely ST1, ST2, and ST4 – seems to be dependent on geographic region, while
83 ST6-ST9 are not as commonly encountered (Beghini et al., 2017; Stensvold and
84 Clark, 2016).

85 Herein, we collected samples from 178 asymptomatic adult humans living in
86 Chiang Rai Province, Thailand and examined the prevalence, genetic diversity and
87 distribution of Blastocystis. The region combines several particularities, which have
88 created a culture and lifestyle that differs from other regions of Thailand. We provide
89 the first subtyping data from the area, thus expanding knowledge on Blastocystis ST
90 distribution and prevalence in the country.

91

92 **2. Materials and Methods**

93

94 **2.1. Ethics statement**

95 The human ethics committee of Mae Fah Luang University approved
96 collection of fecal samples from adult Thai volunteers (License approval number

97 REH-60104). Volunteers signed an informed consent form before participating in the
98 study.

99

100 **2.2. Human subjects**

101 All volunteers were over 18 years old, Thai and lived in Chiang Rai Province
102 at the time of sampling (Fig. 1). In total, 178 adult volunteers participated in the
103 study. The volunteers had no history of gastrointestinal symptoms, no diarrhea
104 episodes a month prior to sampling and had received no antibiotic treatment at least
105 two months prior to sample collection.

106

107 **2.3. Stool collection and DNA extraction**

108 Fecal samples were collected from the volunteers using sealed, sterile
109 containers and stored at -80°C until DNA extraction. Samples were collected from
110 six districts of Chiang Rai Province: Mae Chan (n=20), Mae Lao (n=20), Mae Sai
111 (n=25), Muang (n=69), Pa Daet (n=23) and Phaya Mengrai (n=21) (Fig. 1). Total
112 DNA was isolated using the QIAamp DNA Stool Mini Kit (Qiagen, Thailand)
113 according to manufacturer's specifications. The extracted DNA was stored at -20 °C
114 for later use.

115

116 **2.4. PCR amplification, amplicon purification and sequencing**

117 Polymerase chain reaction (PCR) was used to amplify a 650 bp fragment of
118 the SSUrRNA at the 5' of the gene. This fragment is considered the barcoding region
119 of *Blastocystis* spp. (Scicluna et al., 2006).

120 Two PCR reactions were used to amplify the SSUrRNA gene of *Blastocystis*.

121 The broadly specific primers, RD5 5' –

122 GGAAGCTTATCTGGTTGATCCTGCCAGTA – 3' and RD3 5' –
123 GGGATCCTGATCCTTCCGCAGGTTACCTAC – 3' were used for the primary
124 PCR reaction (Clark, 1997). The total volume of each reaction was 25µl containing
125 the following reagents: 10X reaction buffer, 1 mM MgCl₂, 0.1 mM dNTPs, 0.2 µM
126 forward primer, 0.2 µM reverse primer, 5U Taq DNA polymerase (RBC Bioscience,
127 New Taipei City, Taiwan) and 12 µl HPLC grade water. Cycling conditions were as
128 follows: initial denaturation at 94 °C for 3 min followed by 35 cycles of denaturation
129 at 94 °C for 1 min 40 s, annealing at 65 °C for 1 min 40 s, extension at 72 °C for 1
130 min 40 s followed by a final extension at 72 °C for 10 min.

131 The more narrowly specific primers RD5F 5' – ATCTGGTCGATCCTG
132 CCAGT – 3' and BhRDr 5' – GAGCTTTTAACTGCAACAACG – 3' were
133 employed for the secondary, nested PCR reaction. Reaction volume and concentration
134 of reagents were as in the primary PCR with the exception of the DNA template.
135 Instead of genomic fecal DNA, one µl from the primary PCR reaction was used.
136 Cycling conditions were as follows: denaturation at 94 °C for 3 min, followed by 35
137 cycles of denaturation at 94 °C for 1 min, annealing at 55 °C for 1 min and extension
138 at 72 °C for 1 min and a final extension at 72 °C for 10 min.

139 Positive PCR reactions were purified using the *HiYield*TM Gel/PCR Fragments
140 Extraction Kit (RBC bioscience, USA) according to manufacturer's specifications.
141 Purified PCR products were sequenced by 1stBASE, Malaysia.

142

143 **2.5. Subtyping and phylogenetic analysis**

144 The obtained sequences were examined and poor quality bases at the 5' and
145 3'ends of the sequence were removed. Sequences were then subjected to BLAST
146 search against GenBank database to exclude contamination. Sequences identified as

147 Blastocystis, were further checked against the Blastocystis Subtype Sequence Typing
148 (MLST) publicly available at <http://pubmlst.org/blastocystis/>, in order to identify
149 subtype and the corresponding allele.

150 The new sequences identified as Blastocystis along with sequences spanning
151 the breadth of diversity of Blastocystis (all subtypes and sequences from ectotherms)
152 were used to construct the dataset. In total, 103 sequences were aligned using MAFFT
153 v. 7 (Kato and Toh, 2010), visually inspected and further improved manually.
154 Ambiguous regions were removed with trimAl v. 1.3 (Capella-Gutierrez et al., 2009).
155 After trimming, the alignment contained 1,379 sites. A maximum likelihood (ML)
156 phylogenetic tree was constructed using RAxML v. 8 (Stamatakis, 2006) and the
157 general time reversible + Γ model of nucleotide substitution. The heuristic tree search
158 was based on 20 starting trees. One thousand bootstrap replicates were generated and
159 used for ML analysis. MrBayes v. 3.2.6 (Ronquist and Huelsenbeck, 2003) was used
160 to construct the Bayesian Inference (BI) tree using the same model as above. Two sets
161 of four independent Markov Chain Monte Carlo simulations were run for 1,500,000
162 generations. Sampling was done every 1,000 generations and 25% were discarded as
163 burn-in. Convergence was declared when the standard deviation of split sequences
164 was less than 0.01. Phylogenetic analyses were conducted on the Cipres Science
165 Gateway (<http://www.phylo.org/portal2/home.action>).

166 To further examine distribution of subtypes across Thailand, we downloaded
167 all Blastocystis sequences with the following identifiers: country =Thailand and
168 host=Homo sapiens. In total, 161 Blastocystis sequences were used for the analysis of
169 ST prevalence. For the ST distribution across Thailand 159 were used. Two sequences
170 were removed because the exact locality of collection was not noted.

171

172 **3. Results**

173

174 **3.1. Screening of fecal samples**

175 Of the 178 samples, 41 (23%) were sequence positive for Blastocystis (Table
176 1). Differences were noted in the percent prevalence among districts. The highest
177 prevalence was observed in Phaya Mengrai District (33%), while the lowest was
178 noted in Mae Chan and Mae Lao Districts (15%).

179

180 **3.2. Subtype prevalence and distribution**

181 Blastocystis prevalence in our study population was 23% (41/178). In total, six
182 of the nine STs that colonise humans were identified in this study: ST1 (n=7, 17%),
183 ST2 (n=1, 2%), ST3 (n=28, 68%), ST4 (n=1, 2%), ST6 (n=1, 2%) and ST7 (n=3, 7%).
184 Two alleles of ST1 were detected with the dominant one being allele 4, while four
185 alleles were found within the dominant ST3 (Fig. 2). Even though only three
186 sequences are available for ST7, two alleles were detected, suggesting a high degree
187 of genetic diversity for this ST in the study population. The prevalence of the various
188 Blastocystis subtypes in Thailand resembles the rest of the world (Fig. 3). Subtype 3 is
189 the most prevalent one, followed by ST1, ST2, ST6 and ST7. Nonetheless, notable
190 differences emerge when looking at the prevalence of STs according to geographic
191 region (Fig. 4).

192 All newly generated sequences have been submitted to GenBank (submission
193 number SUB3865516)

194 **3.3. Phylogenetic analyses**

195 All newly derived sequences grouped within clades formed by previously
196 reported STs (Fig. 5). In agreement with previous studies, isolates from ectothermic

197 metazoans and those from ST15, ST16 and ST17 placed at a basal position (Betts et
198 al., 2018; Yoshikawa et al., 2016). Placement of the new sequences confirmed ST
199 predictions from the pubmlst website. The rest of the STs grouped into two large
200 clusters, once consisting of ST3, ST4, ST8 and ST10 and the other formed by the
201 remaining STs.

202

203 **4. Discussion**

204 All samples herein were collected from asymptomatic adults with no history
205 of gastrointestinal disease. Our results match previous recent reports, which have
206 demonstrated asymptomatic carriage of Blastocystis in populations from westernised
207 and non-westernised countries, as well as, rural and urban settings (Lukeš et al.,
208 2015; Parfrey et al., 2014; Scanlan et al., 2014). Findings from analyses of large
209 datasets are also consistent with these observations (Audebert et al., 2016; Beghini et
210 al., 2017). These are in contrast with many previous studies that postulate links of
211 Blastocystis with intestinal diseases and dysbiosis (Poirer et al., 2012; Yakoob et al.,
212 2010). Thus, it is still unclear, whether Blastocystis is a pathogen, a harmless
213 commensal or a beneficial member of gut microbiota. The debate has given rise to the
214 speculation that pathogenicity of Blastocystis is limited to specific genotypes with the
215 majority of them being harmless (Scanlan and Stensvold, 2013; Tan et al., 2010).
216 Given the polymicrobial nature of the gut, an as yet unexplored theme in the context
217 of ecological theory, is whether Blastocystis becomes pathogenic through synergistic
218 action with other microbes and/or their metabolic products. Nonetheless, the
219 asymptomatic carriage of Blastocystis found in our study and others reinforces the
220 idea of it being a part of the healthy gut microbiota.

221 We used PCR to amplify the barcoding region of *Blastocystis* (Sciicluna et al.,
222 2006) from 178 fecal samples. This method demonstrated that the overall prevalence
223 of *Blastocystis* in our study population was 23%. It is difficult to determine how this
224 prevalence rate compares to other studies from Thailand. *Blastocystis* detection in the
225 country is primarily based on microscopy (Boonjaraspinyo et al., 2013; Kitvatanachai
226 and Rhongbutsri, 2013; Kitvatanachai et al., 2008; Ngrenngarmlert et al., 2007;
227 Pipatsatitpong et al., 2012; Sagnuankiat et al., 2014). In general, microscopy is less
228 sensitive and underestimates prevalence. Molecular-based studies on *Blastocystis*
229 constitute a recent development and remain extremely limited (Boondit et al., 2014;
230 Jantermtor et al., 2013; Palasuwan et al., 2016; Pintong et al., 2014; Pipatsatitpong et
231 al., 2015; Popruk et al., 2015; Thathaisong et al., 2013). These molecular surveys
232 have shown prevalence ranging from 6% to 51%. The observed variable data from our
233 study and others could be the result of demographically different populations being
234 surveyed. For instance, the highest abundance of *Blastocystis* was found in orphan
235 male children, while residents of communities along Chao Praya River in Ayutthaya
236 Province (central Thailand) had the lowest prevalence (Palasuwan et al., 2016;
237 Pintong et al., 2014). Age, health status of the individuals, and general lifestyle are
238 likely contributing factors accounting for the observed differences among studies
239 (Leelayoova et al., 2008).

240 Subtyping of *Blastocystis* positive samples identified six of the nine STs
241 known to colonise humans: ST1, ST2, ST3, ST4, ST6 and ST7. ST3 was dominant
242 and present in two thirds of the samples, followed by ST1 and ST7. This is slightly
243 different than the global trend, whereby ST3, ST1 and ST2, in this order, are the most
244 frequently encountered (Stensvold and Clark, 2016). This pattern is also noted in
245 molecular surveys of *Blastocystis* in neighboring Southeast Asian countries (Laos,

246 Cambodia and Malaysia), except for Laos, where ST1 was the most frequent followed
247 by ST3 and then ST2 (Nithyamathi et al., 2016; Noradilah et al., 2017; Sanpool et al.,
248 2017; Wang et al., 2014). Herein, ST2, ST4 and ST6 were found in a single individual
249 each. ST4 is a geography-influenced ST and is typically found in Europe, where it is
250 abundant and highly prevalent (Alfellani et al., 2013b; Beghini et al., 2017; Forsell et
251 al., 2016;). Indeed, ST4 occurrence in Southeast Asia is extremely rare having been
252 found so far only in Thailand and Malaysia (Nithyamathi et al., 2016; Noradilah et
253 al., 2017; Popruk et al., 2015).

254 When all available sequences from human stool samples from Thailand are
255 taken into account (including ours), the most prevalent STs are ST3, ST1 and ST2, a
256 pattern that follows the global trend (Stensvold and Clark, 2016). Given the known
257 influence of geography on ST distribution, we zoomed into specific regions. Based on
258 geography, Thailand is divided into four regions: north, northeast, center and south.
259 Thus, when geographic region is taken into account, there are some notable
260 differences in the ST distribution. For instance, the relative abundance of ST3 and
261 ST1 changes. ST1 is dominant in the center, while ST3 dominates in the north and
262 northeast. ST2 is absent in the northeast, whilst ST4 has only been found so far in the
263 north. Importantly, the center, which is the most urbanised region of Thailand, has the
264 least number of subtypes. Incidentally, this is also the most broadly surveyed region
265 and where most sequences come from. Thus, though we cannot exclude the possibility
266 that some STs circulate in the center and have yet to be detected, this is not very
267 likely. Presence of ST6 and ST7 in the north and northeast could be attributed to
268 domestic fowl, especially chickens and geese, which live in close proximity to
269 humans.

270 The data obtained herein are the first on prevalence of Blastocystis and
271 distribution of STs in asymptomatic individuals living in Chiang Rai Province. Our
272 data along with other molecular data from Thailand will contribute to the knowledge
273 on the epidemiology of Blastocystis in the country. Nonetheless, major gaps exist, in
274 that: 1) molecular data on Blastocystis from Thailand is scant, thus ST distribution is
275 largely unknown and, 2) the majority of Thai communities have yet to be sampled.
276 For example, there is no molecular data of Blastocystis from the south part of
277 Thailand. Moving forward, future studies should expand to generate subtyping
278 information from more communities across Thailand and also include symptomatic
279 individuals.

280

281 **CONFLICTS OF INTEREST**

282 The authors declare no conflict of interest

283

284 **ACKNOWLEDGMENTS**

285 We are grateful to all the volunteers that participated in this study. We also wish to
286 acknowledge the Human Gut Microbiome for Health Research Unit, Mae Fah Luang
287 University, Chiang Rai, Thailand.

288

289 **FINANCIAL SUPPORT**

290 This project was supported by the Thailand Research Fund (RSA6080048) awarded to
291 E.G. A.D.T. was supported by BBSRC research grant (BB/M009971/1).

22 **Abstract**

23

24 Blastocystis is a common and broadly distributed microbial eukaryote inhabiting the
25 gut of humans and other animals. The genetic diversity of Blastocystis is extremely
26 high comprising no less than 17 subtypes in mammals and birds. Nonetheless, little is
27 known about the prevalence and distribution of Blastocystis subtypes colonising
28 humans in Thailand. Molecular surveys of Blastocystis remain extremely limited and
29 usually focus on the central, urban part of the country. To address this knowledge gap,
30 we collected stool samples from a population of Thai adults (n=178) residing in
31 Chiang Rai Province. The barcoding region of the small subunit ribosomal RNA was
32 employed to screen for Blastocystis and identify the subtype. Forty-one stool samples
33 (23%) were identified as Blastocystis positive. Six of the nine subtypes that colonise
34 humans were detected with subtype (ST) three being the most common (68%),
35 followed by ST1 (17%) and ST7 (7%). Comparison of subtype prevalence across
36 Thailand using all publicly available sequences showed that subtype distribution
37 differs among geographic regions in the country. ST1 was most commonly
38 encountered in the central region of Thailand, while ST3 dominated in the more rural
39 north and northeast regions. ST2 was absent in the northeast, while ST7 was not
40 found in the center. Thus, this study shows that ST prevalence and distribution differs
41 not only among countries, but also among geographic regions within a country.
42 Potential explanations for these observations are discussed herewith.

43

44

45 **Keywords:** Blastocystis; genetic diversity; prevalence; subtyping; Thailand

46

47 1. Introduction

48

49 Blastocystis is the most commonly found protist in the gastrointestinal tract of
50 humans and other animals (Roberts et al., 2013; Tan, 2008). Though Blastocystis
51 exhibits morphological stasis, it has a high degree of genetic heterogeneity. Isolates
52 from avian and mammalian hosts are~~The organism is~~ currently classified into 17
53 subtypes (STs) based on the divergence of the small subunit ribosomal RNA (SSU
54 rRNA), though new STs might be arising (Alfellani et al., 2013c; Betts et al., 2018;).
55 Blastocystis isolated from reptilian, amphibian and insect hosts are distinct and are not
56 assigned into subtypes. So far, only ST1-ST9 have been found in humans with ST1-
57 ST4 being the most common colonisers (Alfellani et al., 2013b). However, these STs
58 have also been detected in a variety of non-human hosts, suggesting that Blastocystis
59 has low host specificity (Stensvold and Clark 2016). The exception is ST9, which has
60 yet to be found in non-human hosts. The rest of the STs have so far been identified in
61 both domesticated and wildlife animal hosts (Alfellani et al., 2013a).

62 Lately, considerable research effort has gone into deciphering potential roles
63 of Blastocystis in intestinal disease. For instance, an association between presence of
64 Blastocystis and irritable bowel syndrome has been discussed frequently, though a
65 definitive causal link has yet to be postulated (Jimenez-Gonzalez et al., 2012;
66 Khademvatan et al., 2017; Poirer et al., 2012; Yakoob et al., 2010). Nonetheless,
67 emerging data have shown presence of Blastocystis in asymptomatic individuals
68 leading to the hypothesis that the organism is part of the healthy adult gut microbiota
69 and that only specific STs and/or genotypes might be pathogenic (Chabe et al., 2017;
70 Scanlan and Stensvold, 2013; Scanlan et al., 2014; Stensvold and van der Giezen,
71 2018). In this context, surveys examining prevalence of Blastocystis should ideally be

72 accompanied by subtyping. Thus, while the cosmopolitan status of Blastocystis is well
73 established, geographic distribution of specific subtypes and their prevalence are
74 relatively recent endeavors.

75 Research efforts on the latter two are disproportionate among countries and/or
76 geographic regions: a plethora of Blastocystis studies come from the Americas and
77 Europe, whilst Asia remains disproportionately sampled, given that half of the earth's
78 population resides in Asian countries (El Safadi et al., 2016; Scanlan et al., 2016;
79 Villegas-Gomez et al., 2016). Collectively, these studies have shown that ST3 is the
80 most prevalent one in almost all regions that have been examined, with a notable
81 exception (Oliveira-Arbex et al., 2018). Prevalence of the other common STs –
82 namely ST1, ST2, and ST4 – seems to be dependent on geographic region, while
83 ST6-ST9 are not as commonly encountered (Beghini et al., 2017; Stensvold and
84 Clark, 2016).

85 Herein, we collected samples from 178 asymptomatic adult humans living in
86 Chiang Rai Province, Thailand and examined the prevalence, genetic diversity and
87 distribution of Blastocystis. The region combines several particularities, which have
88 created a culture and lifestyle that differs from other regions of Thailand. We provide
89 the first subtyping data from the area, thus expanding knowledge on Blastocystis ST
90 distribution and prevalence in the country.

91

92 **2. Materials and Methods**

93

94 **2.1. Ethics statement**

95 The human ethics committee of Mae Fah Luang University approved
96 collection of fecal samples from adult Thai volunteers (License approval number

97 REH-60104). Volunteers signed an informed consent form before participating in the
98 study.

99

100 **2.2. Human subjects**

101 All volunteers were over 18 years old, Thai and lived in Chiang Rai Province
102 at the time of sampling (Fig. 1). In total, 178 adult volunteers participated in the
103 study. The volunteers had no history of gastrointestinal symptoms, no diarrhea
104 episodes a month prior to sampling and had received no antibiotic treatment at least
105 two months prior to sample collection.

106

107 **2.3. Stool collection and DNA extraction**

108 Fecal samples were collected from the volunteers using sealed, sterile
109 containers and stored at -80°C until DNA extraction. Samples were collected from
110 six districts of Chiang Rai Province: Mae Chan (n=20), Mae Lao (n=20), Mae Sai
111 (n=25), Muang (n=69), Pa Daet (n=23) and Phaya Mengrai (n=21) (Fig. 1). Total
112 DNA was isolated using the QIAamp DNA Stool Mini Kit (Qiagen, Thailand)
113 according to manufacturer's specifications. The extracted DNA was stored at -20 °C
114 for later use.

115

116 **2.4. PCR amplification, amplicon purification and sequencing**

117 Polymerase chain reaction (PCR) was used to amplify a 650 bp fragment of
118 the SSUrRNA at the 5' of the gene. This fragment is considered the barcoding region
119 of *Blastocystis* spp. (Scicluna et al., 2006).

120 Two PCR reactions were used to amplify the SSUrRNA gene of *Blastocystis*.

121 The broadly specific primers, RD5 5' –

122 GGAAGCTTATCTGGTTGATCCTGCCAGTA – 3' and RD3 5' –
123 GGGATCCTGATCCTTCCGCAGGTTACCTAC – 3' were used for the primary
124 PCR reaction (Clark, 1997). The total volume of each reaction was 25µl containing
125 the following reagents: 10X reaction buffer, 1 mM MgCl₂, 0.1 mM dNTPs, 0.2 µM
126 forward primer, 0.2 µM reverse primer, 5U Taq DNA polymerase (RBC Bioscience,
127 New Taipei City, Taiwan) and 12 µl HPLC grade water. Cycling conditions were as
128 follows: initial denaturation at 94 °C for 3 min followed by 35 cycles of denaturation
129 at 94 °C for 1 min 40 s, annealing at 65 °C for 1 min 40 s, extension at 72 °C for 1
130 min 40 s followed by a final extension at 72 °C for 10 min.

131 The more narrowly specific primers RD5F 5' – ATCTGGTCGATCCTG
132 CCAGT – 3' and BhRDr 5' – GAGCTTTTAACTGCAACAACG – 3' were
133 employed for the secondary, nested PCR reaction. Reaction volume and concentration
134 of reagents were as in the primary PCR with the exception of the DNA template.
135 Instead of genomic fecal DNA, one µl from the primary PCR reaction was used.
136 Cycling conditions were as follows: denaturation at 94 °C for 3 min, followed by 35
137 cycles of denaturation at 94 °C for 1 min, annealing at 55 °C for 1 min and extension
138 at 72 °C for 1 min and a final extension at 72 °C for 10 min.

139 Positive PCR reactions were purified using the *HiYield*TM Gel/PCR Fragments
140 Extraction Kit (RBC bioscience, USA) according to manufacturer's specifications.
141 Purified PCR products were sequenced by 1stBASE, Malaysia.

142

143 **2.5. Subtyping and phylogenetic analysis**

144 The obtained sequences were examined and poor quality bases at the 5' and
145 3'ends of the sequence were removed. Sequences were then subjected to BLAST
146 search against GenBank database to exclude contamination. Sequences identified as

147 Blastocystis, were further checked against the Blastocystis Subtype Sequence Typing
148 (MLST) publicly available at <http://pubmlst.org/blastocystis/>, in order to identify
149 subtype and the corresponding allele.

150 The new sequences identified as Blastocystis along with sequences spanning
151 the breadth of diversity of Blastocystis (all subtypes and sequences from ectotherms)
152 were used to construct the dataset. In total, 103 sequences were aligned using MAFFT
153 v. 7 (Kato and Toh, 2010), visually inspected and further improved manually.
154 Ambiguous regions were removed with trimAl v. 1.3 (Capella-Gutierrez et al., 2009).
155 After trimming, the alignment contained 1,379 sites. A maximum likelihood (ML)
156 phylogenetic tree was constructed using RAxML v. 8 (Stamatakis, 2006) and the
157 general time reversible + Γ model of nucleotide substitution. The heuristic tree search
158 was based on 20 starting trees. One thousand bootstrap replicates were generated and
159 used for ML analysis. MrBayes v. 3.2.6 (Ronquist and Huelsenbeck, 2003) was used
160 to construct the Bayesian Inference (BI) tree using the same model as above. Two sets
161 of four independent Markov Chain Monte Carlo simulations were run for 1,500,000
162 generations. Sampling was done every 1,000 generations and 25% were discarded as
163 burn-in. Convergence was declared when the standard deviation of split sequences
164 was less than 0.01. Phylogenetic analyses were conducted on the Cipres Science
165 Gateway (<http://www.phylo.org/portal2/home.action>).

166 To further examine distribution of subtypes across Thailand, we downloaded
167 all Blastocystis sequences with the following identifiers: country =Thailand and
168 host=Homo sapiens. In total, 161 Blastocystis sequences were used for the analysis of
169 ST prevalence. For the ST distribution across Thailand 159 were used. Two sequences
170 were removed because the exact locality of collection was not noted.

171

172 **3. Results**

173

174 **3.1. Screening of fecal samples**

175 Of the 178 samples, 41 (23%) were sequence positive for Blastocystis (Table
176 1). Differences were noted in the percent prevalence among districts. The highest
177 prevalence was observed in Phaya Mengrai District (33%), while the lowest was
178 noted in Mae Chan and Mae Lao Districts (15%).

179

180 **3.2. Subtype prevalence and distribution**

181 Blastocystis prevalence in our study population was 23% (41/178). In total, six
182 of the nine STs that colonise humans were identified in this study: ST1 (n=7, 17%),
183 ST2 (n=1, 2%), ST3 (n=28, 68%), ST4 (n=1, 2%), ST6 (n=1, 2%) and ST7 (n=3, 7%).
184 Two alleles of ST1 were detected with the dominant one being allele 4, while four
185 alleles were found within the dominant ST3 (Fig. 2). Even though only three
186 sequences are available for ST7, two alleles were detected, suggesting a high degree
187 of genetic diversity for this ST in the study population. The prevalence of the various
188 Blastocystis subtypes in Thailand resembles the rest of the world (Fig. 3). Subtype 3 is
189 the most prevalent one, followed by ST1, ST2, ST6 and ST7. Nonetheless, notable
190 differences emerge when looking at the prevalence of STs according to geographic
191 region (Fig. 4).

192 All newly generated sequences have been submitted to GenBank (submission
193 number SUB3865516)

194 **3.3. Phylogenetic analyses**

195 All newly derived sequences grouped within clades formed by previously
196 reported STs (Fig. 5). In agreement with previous studies, isolates from ectothermic

197 metazoans and those from ST15, ST16 and ST17 placed at a basal position (Betts et
198 al., 2018; Yoshikawa et al., 2016). Placement of the new sequences confirmed ST
199 predictions from the pubmlst website. The rest of the STs grouped into two large
200 clusters, once consisting of ST3, ST4, ST8 and ST10 and the other formed by the
201 remaining STs.

202

203 **4. Discussion**

204 All samples herein were collected from asymptomatic adults with no history
205 of gastrointestinal disease. Our results match previous recent reports, which have
206 demonstrated asymptomatic carriage of Blastocystis in populations from westernised
207 and non-westernised countries, as well as, rural and urban settings (Lukeš et al.,
208 2015; Parfrey et al., 2014; Scanlan et al., 2014). Findings from analyses of large
209 datasets are also consistent with these observations (Audebert et al., 2016; Beghini et
210 al., 2017). These are in contrast with many previous studies that postulate links of
211 Blastocystis with intestinal diseases and dysbiosis (Poirer et al., 2012; Yakoob et al.,
212 2010). Thus, it is still unclear, whether Blastocystis is a pathogen, a harmless
213 commensal or a beneficial member of gut microbiota. ~~The debate has~~ **These contrary**
214 **findings have** given rise to the speculation that pathogenicity of Blastocystis is limited
215 to specific genotypes with the majority of them being harmless (Scanlan and
216 Stensvold, 2013; Tan et al., 2010). Given the polymicrobial nature of the gut, an as
217 yet unexplored theme in the context of ecological theory, is whether Blastocystis
218 becomes pathogenic through synergistic action with other microbes and/or their
219 metabolic products. Nonetheless, the asymptomatic carriage of Blastocystis found in
220 our study **and others** reinforces the idea of it being a part of the healthy gut
221 microbiota.

222 We used PCR to amplify the barcoding region of *Blastocystis* (Sciicluna et al.,
223 2006) from 178 fecal samples. This method demonstrated that the overall prevalence
224 of *Blastocystis* in our study population was 23%. It is difficult to determine how this
225 prevalence rate compares to other studies from Thailand. *Blastocystis* detection in the
226 country is primarily based on microscopy (Boonjaraspinyo et al., 2013; Kitvatanachai
227 and Rhongbuttsri, 2013; Kitvatanachai et al., 2008; Ngrenngarmert et al., 2007;
228 Pipatsatitpong et al., 2012; Sagnuankiat et al., 2014). In general, microscopy is less
229 sensitive and underestimates prevalence. Molecular-based studies on *Blastocystis*
230 constitute a recent development and remain extremely limited (Boondit et al., 2014;
231 Jantermtor et al., 2013; Palasuwan et al., 2016; Pintong et al., 2014; Pipatsatitpong et
232 al., 2015; Popruk et al., 2015; Thathaisong et al., 2013). These molecular surveys
233 have shown prevalence ranging from 6% to 51%. The observed variable data from our
234 study and others could be the result of demographically different populations being
235 surveyed. For instance, the highest abundance of *Blastocystis* was found in orphan
236 male children, while residents of communities along Chao Praya River in Ayutthaya
237 Province (central Thailand) had the lowest prevalence (Palasuwan et al., 2016;
238 Pintong et al., 2014). Age, health status of the individuals, and general lifestyle are
239 likely contributing factors accounting for the observed differences among studies
240 (Leelayoova et al., 2008).

241 Subtyping of *Blastocystis* positive samples identified six of the nine STs
242 known to colonise humans: ST1, ST2, ST3, ST4, ST6 and ST7. ST3 was dominant
243 and present in two thirds of the samples, followed by ST1 and ST7. This is slightly
244 different than the global trend, whereby ST3, ST1 and ST2, in this order, are the most
245 frequently encountered (Stensvold and Clark, 2016). This pattern is also noted in
246 molecular surveys of *Blastocystis* in neighboring Southeast Asian countries (Laos,

247 Cambodia and Malaysia), except for Laos, where ST1 was the most frequent followed
248 by ST3 and then ST2 (Nithyamathi et al., 2016; Noradilah et al., 2017; Sanpool et al.,
249 2017; Wang et al., 2014). Herein, ST2, ST4 and ST6 were found in a single individual
250 each. ST4 is a geography-influenced ST and is typically found in Europe, where it is
251 abundant and highly prevalent (Alfellani et al., 2013b; Beghini et al., 2017; Forsell et
252 al., 2016;). Indeed, ST4 occurrence in Southeast Asia is extremely rare having been
253 found so far only. ~~In molecular surveys taking place~~ in Thailand ~~only two cases of~~
254 ~~ST4 have been found: one in this study and another from Tak, a northwestern~~
255 ~~province bordering Myanmar (Popruk et al., 2015).~~ ~~In the neighboring countries of~~
256 ~~Laos, Cambodia, and Malaysia, ST4 has been found only in Malaysia~~ (Nithyamathi et
257 al., 2016; Noradilah et al., 2017; Popruk et al., 2015). ~~Regrettably, there is no~~
258 ~~publicly available data on Blastocystis from Myanmar.~~ ~~Alfellani et al., (2013b), noted~~
259 ~~that ST4 occurs rarely in places, where ST1 dominates, and/or in regions where~~
260 ~~Muslim populations predominate, an observation that has since been reinforced~~
261 ~~(Forsell et al., 2016).~~ ~~Another explanation could be that the Thai ST4 cases represent~~
262 ~~imports from Europe. Though none of the participants in our study travelled to~~
263 ~~Europe, it is unknown, if other household members did. If this indeed were the case, it~~
264 ~~would be interesting to see how the newly arrived STs affect the resident microbiota.~~

265 When all available sequences from human stool samples from Thailand are
266 taken into account (including ours), the most prevalent STs are ST3, ST1 and ST2, a
267 pattern that follows the global trend (Stensvold and Clark, 2016). Given the known
268 influence of geography on ST distribution, we zoomed into specific regions. Based on
269 geography, Thailand is divided into four regions: north, northeast, center and south.
270 Thus, when geographic region is taken into account, there are some notable
271 differences in the ST distribution. For instance, the relative abundance of ST3 and

272 ST1 changes. ST1 is dominant in the center, while ST3 dominates in the north and
273 northeast. ST2 is absent in the northeast, whilst ST4 has only been found so far in the
274 north. Importantly, the center, which is the most urbanised region of Thailand, has the
275 least number of subtypes. Incidentally, this is also the most broadly surveyed region
276 and where most sequences come from. Thus, though we cannot exclude the possibility
277 that some STs circulate in the center and have yet to be detected, this is not very
278 likely. ~~Presence of ST6 and ST7 in~~ Explaining these differences is a challenging
279 endeavor. It is known that the four geographic regions of Thailand also happen to be
280 gastronomically distinct. In particular, the north and northeast could be attributed to
281 domestic fowl, and most especially chickens and geese, which live in close proximity
282 to humans ~~Chiang Rai is of interest, because of its northernmost location (Fig. 1) and~~
283 ~~the mixed influence of nearby Laos and Myanmar on daily life, including diet. In a~~
284 ~~broader context, and given the influence of diet on microbial communities, the~~
285 ~~observed differences in ST distribution could also reflect differences in gut microbiota~~
286 ~~composition. In that vein, recent data have demonstrated that Blastocystis is more~~
287 ~~prevalent in individuals with increased Prevotella and Ruminococcus and decreased~~
288 ~~Bacteroides (Andersen and Stensvold, 2015; Audebert et al., 2016; Beghini et al.,~~
289 ~~2017; O'Brien Andersen et al., 2016;). Nonetheless, a knowledge gap exists, as to~~
290 ~~whether similar differences drive prevalence of specific STs and vice versa.~~

291 The data obtained herein are the first on prevalence of Blastocystis and
292 distribution of STs in asymptomatic individuals living in Chiang Rai Province, ~~and~~
293 ~~one of the few in Thailand.~~ Our data along with other molecular data from Thailand
294 will contribute to the knowledge on the epidemiology of Blastocystis in the country.
295 Nonetheless, major gaps exist, in that: 1) molecular data on Blastocystis from
296 Thailand is scant, thus ST distribution is largely unknown and, 2) the majority of Thai

297 communities have yet to be sampled. For example, there is no molecular data of
298 Blastocystis from the south part of Thailand. Moving forward, future studies should
299 expand to generate subtyping information ~~from~~and include more communities
300 ~~acrossnot only from~~ Thailand and also include symptomatic individuals, but
301 neighboring countries as well.

302

303 **CONFLICTS OF INTEREST**

304 The authors declare no conflict of interest

305

306 **ACKNOWLEDGMENTS**

307 We are grateful to all the volunteers that participated in this study. We also wish to
308 acknowledge the Human Gut Microbiome for Health Research Unit, Mae Fah Luang
309 University, Chiang Rai, Thailand.

310

311 **FINANCIAL SUPPORT**

312

313 This project was supported by the Thailand Research Fund (RSA6080048) awarded to
314 E.G. A.D.T. was supported by BBSRC research grant (BB/M009971/1).

488 **FIGURE LEGENDS**

489 **Fig. 1.** Map of Thailand and Chiang Rai Province districts. Sampling localities used in
490 this investigation are depicted in red lettering.

491 **Fig. 2.** Frequency of Blastocystis alleles detected in the study population

492 **Fig. 3.** Prevalence of Blastocystis subtypes in Thailand (n=161)

493 **Fig. 4.** Prevalence and distribution of Blastocystis subtypes across geographic regions
494 in Thailand

495 **Fig. 5.** Maximum likelihood phylogenetic tree inferred from 103 SSUrRNA
496 sequences and 1379 sites. New sequences are depicted in bold lettering. Numerical
497 values on the tree branches indicate bootstrap support percentages and posterior
498 probabilities in this order.
