Abstract

Golden Gate cloning is a prominent DNA assembly tool in synthetic biology for the assembly of plasmid constructs often used in combinatorial pathway optimisation, with a number of assembly kits developed specifically for yeast and plant-based expression. However, its use for synthetic biology in commonly used bacterial systems such as *Escherichia coli*, has surprisingly been overlooked. Here, we introduce EcoFlex a simplified modular package of DNA parts for a variety of applications in *E. coli*, cell-free protein synthesis, protein purification and hierarchical assembly of transcription units based on the MoClo assembly standard. The kit features a library of constitutive promoters, T7 expression, RBS strength variants, synthetic terminators, protein purification tags and fluorescence proteins. We validate EcoFlex by assembling a 68-part containing (20 genes) plasmid (31 kb), characterise *in vivo* and *in vitro* library parts, and perform combinatorial pathway assembly, using pooled libraries of either fluorescent proteins or the biosynthetic genes for the antimicrobial pigment violacein as a proof-of-concept. To minimise pathway screening, we also introduce a secondary module design site to simplify MoClo pathway optimisation. In summary, EcoFlex provides a standardised and multifunctional kit for a variety of applications in *E. coli* synthetic biology.

Keywords

Synthetic biology, Golden Gate, *Escherichia coli*, recombinant protein production, cell-free protein synthesis, violacein

Introduction

A prime target for synthetic biology is the production of natural and commodity chemical products such as drug precursors, fine and specialised chemicals and biofuels using renewable feedstocks¹. This is driven by the need to transition away from a current reliance on petroleum-derived chemical products and production processes. A more sustainable and environmentally friendly solution to this problem is in the application of synthetic biology to engineer enzyme biosynthetic pathways primarily within microbial cells to produce such chemical products. Essential to the synthetic biology workflow is the use of rapid, efficient and hierarchical DNA assembly techniques and a number of methods have been proposed². One such method, Golden Gate cloning, is a modular, combinatorial technique used for a wide spectrum of DNA assembly applications, from the construction of simple transcription units (TUs) to diverse biochemical pathway libraries originally developed by Marillonnet and colleagues³⁻⁵.

Golden Gate cloning utilises the non-palindromic type IIS restriction endonuclease BsaI, which cuts outside of its recognition sequence (GGTCTCN[↓]NNNN), producing a four base pair overhang. This overhang, also known as a fusion site, can be designed to provide directional DNA part assembly. BsaI sites are placed at both the 5' and 3' ends of a DNA part in inverse orientation, allowing the restriction site to be removed before assembly by the T4 DNA ligase. DNA parts are held within "entry vectors" and can include promoters, protein tags, ribosome-binding sites (RBS), open reading frames (ORF), protein domains, TALEN repeats⁶, fusion linkers and terminators. A combined one-pot reaction of "entry vectors" is then digested and ligated into "destination vectors" using BsaI and T4 DNA ligase. Golden Gate assembly has been demonstrated to assemble up to 10 DNA fragments with greater than 95% efficiency⁵ and relies solely on the use of the BsaI enzyme. Recently, modifications to the original Golden Gate cloning technique have included Golden Braid and MoClo standards^{7,8}, which rely on the use of alternating antibiotic marker plasmids and dual type IIS endonucleases (BsaI/BsmBI or BsaI/BpiI) to rapidly construct hierarchical multi-gene pathways up to 33 kb in size⁹. In summary, several plasmid kits have been developed including MoClo and GoldenBraid for plants^{7,10,11}, *Saccharomyces cerevisiae*^{12,13} and *Schizosaccharomyces pombe*¹⁴. For a detailed review of assembly strategies utilising type IIS endonucleases please see Casini *et al*². Focusing on MoClo, this particular assembly scheme allows flexible design of multiple transcription units into modular pathways with each gene under the control of its own promoter, RBS and terminator.

Until the recent release of the CIDAR MoClo kit¹⁵, Golden Gate assembly kits for commonly used bacterial systems such as *E. coli* have surprisingly been overlooked. CIDAR focuses on an automated workflow for MoClo assembly.

1
2
3 However, we wanted to expand this further by modifying and creating a new
4 flexible Golden Gate tool kit specifically for *E. coli* synthetic biology, based on
5 a custom-designed modular library of standard biological parts for hierarchical
6 DNA assembly and optimisation, using the MoClo assembly standard⁹.
7 Herein, we present EcoFlex, a user-friendly, characterised and customisable
8 Golden Gate kit with parts that can be used for example in combinatorial
9 pathway optimisation, cell-free circuit design, recombinant protein purification
10 and in the future genome engineering. We have also included a custom-
11 designed library of constitutive σ^{70} promoters, inducible expression based on
12 the T7 RNA polymerase, a standardised RBS library and a range of synthetic
13 terminators previously characterised¹⁶. The EcoFlex kit also provides options
14 for recombinant protein production and purification, such as N-terminal linkers
15 for hexahistidine and Strep(II)-tag purification, with either constitutive or T7-
16 inducible expression as single parts or combined with a T7 promoter, RBS,
17 His₆-tag and thrombin cleavage site. We also provide a plasmid cassette
18 system (and individual parts) for inducible T7 RNA polymerase (RNAP)
19 production and purification (Figure S6). We validate T7 RNAP activity using
20 cell-free protein synthesis (CFPS). We have also made two improvements to
21 the MoClo system, firstly by simplifying the storage plasmid for open reading
22 frames (ORFs) and secondly we introduce a secondary site to offer flexibility
23 in pathway design. For example, three TUs can be placed in the secondary
24 module under constant expression, whilst the primary site can be used to
25 assemble and optimise a specific gene, regulatory cascade or biosynthetic
26 pathway.

35 In synthetic biology, there is an increasing need to provide a repertoire of
36 biological parts (promoters, RBS, terminators) characterised in the context of
37 the chosen DNA assembly technique. For example, DNA parts can behave
38 differently when placed in a different context (known as “context
39 dependency”), which directly challenges the engineering dogma surrounding
40 synthetic biology. A number of investigators have tried to address this
41 problem through the design of neutral insulator sequences^{17–19}. To
42 understand such effects in our EcoFlex kit, we have validated our library of
43 biological parts both *in vivo* and *in vitro* (in cell-free reactions). To
44 demonstrate the broad utility of EcoFlex, we also provide exemplars of rapidly
45 assembling and purifying His₆-tagged proteins, rational library design using
46 flow-cytometry and the optimisation of the violacein biosynthetic pathway
47 using a secondary MoClo module to simply pathway design and increase the
48 frequency of successful library assemblies.

Results and Discussion

E. coli is one of the major workhorses in synthetic biology, providing a very well-studied chassis for the manipulation of genetic circuits and implementation of biosynthetic pathways. Using a repertoire of biological parts, modular DNA pathways can be efficiently assembled using a range of techniques such as Golden Gate assembly³, BglBricks²⁰, AQUA²¹, BASIC²² and unique nucleotide sequence (UNS)-guided assembly²³. In addition, other cloning methods include PCR and restriction enzyme-based cloning, Gibson assembly²⁴ and sequence-ligation independent cloning²⁵. Eventually we desire to assemble a universal cloning system based on the MoClo standard for prokaryotic host expression to allow an ORF or DNA part (e.g. promoter, RBS) to be easily portable between multiple systems. To begin building this foundation, we unveil EcoFlex that is designed to provide users a flexible combinatorial library toolbox that can also be customised for variety of synthetic biology applications in *E. coli*.

The EcoFlex toolbox

We have built a versatile Golden Gate toolbox based on the MoClo assembly standard⁹ for *E. coli* synthetic biology, which we make available through AddGene (www.addgene.org/cloning/moclo/freemont-ecoflex). To design this kit, we focused on providing flexibility and compatibility with a variety of applications such as pathway assembly, cell-free protein synthesis (CFPS) and recombinant protein purification (Figure 1). Promoters, RBS, tags, ORFs and terminator “parts” were assembled and stored in Level 0 “entry vectors” with chloramphenicol resistance gene and pMB1 origin of replication. A unique feature of our assembly kit is the “entry vector” for storing ORFs (pBP-ORF), whereby to standardise the cloning procedure, each gene is PCR cloned into NdeI and BamHI sites, which are flanked by inverse BsaI sites for Golden Gate assembly. The NdeI (**CATATG**) site provides the fusion site (in bold) for Golden Gate assembly to the RBS sequence (or N-terminal tag) and the start codon for each gene, so no additional amino acids are added to the encoded protein. Optionally, if NdeI or BamHI sites are located within the gene, a NcoI site is also provided in the vector, whilst BglIII, which produces cohesive ends can be used in place of BamHI. ORFs can also be cloned with flanking BsaI restriction sites with compatible fusion sites (5' CATA and 3' TCGA). With NdeI and BamHI cloning, these genes are also suitable for transfer between some of the commercial pET vectors (e.g. pET3a, pET14b, pET15b) for the purpose of recombinant protein production. Alternatively, our kit also provides customized N-terminal fusion tags with either constitutive or T7 RNA polymerase-dependent expression. The “entry vectors” pBP-*lacZ* α and pBP-ORF are customizable for assembly of new promoter parts or ORFs. Further instructions for user modifications are provided in the SI text.

1
2
3 The first tier of assembly (Level 1) requires Bsal to assemble monocistronic
4 TUs, with each ORF under control of its own unique promoter, RBS and
5 transcription terminator (Figure 1A). This is ligated into a “destination vector”
6 backbone (pTU1-A, -B, -C, -D) containing a pMB1 origin and β -lactamase
7 gene. Level 1 fusion sites and assembly options are summarised in Figure
8 1B. Level 1 TUs contain flanking inverse BsmBI sites, which are subsequently
9 used to direct the MoClo (Level 2) stage of assembly (ABCD). The pTU1-A, -
10 B, -C and -D (Level 1) plasmids allow assembly of 2-4 TUs into the Level 2
11 “destination vectors” pTU2-a (to accommodate 2 TUs), -b (3 TUs) and pTU2-
12 A, -B, -C and -D (4 TUs). In addition, optional pTU1-D₁ and pTU1-E Level 1
13 plasmids also allow an additional Golden Gate fusion site for assembly up to 5
14 TUs in pTU2-A, -B, -C or -D. Level 2 plasmids are available with either *lacZ* α
15 or RFP negative markers, a selection of origins of replication (pMB1, ColE1
16 and p15A) and a chloramphenicol resistance marker. For larger pathways, up
17 to 20 TUs can be assembled into a Level 3 “destination vector” (pTU3-A for 2
18 pTU2 plasmids; pTU3-B for 4 pTU2 plasmids).

19
20
21
22
23
24
25 Significantly, we have modified the MoClo system to include a secondary
26 module. This is a unique feature to EcoFlex, whereby separate modules of
27 Level 2 TUs (2-5 TUs) derived from pTU2-a, -b or -A plasmids can be sub-
28 cloned into a secondary site (pTU2^S-A, -a, or -b), using two compatible Bpil
29 sites, which is located upstream of the primary MoClo BsmBI assembly site
30 (Figure 1C). We have introduced this secondary module site as an aid to
31 minimise pathway diversity and increase assembly efficiency during
32 combinatorial optimisation. For example, instead of optimising a six-gene
33 pathway randomly, one module of 2 or 3 TUs can be placed in the secondary
34 module, whilst the remaining 4 or 3 TUs, respectively, are randomised in the
35 primary module. This is important since the screening technique and
36 transformation efficiency are major limiting factors for library screening. An
37 example of its use is demonstrated with the violacein pathway (see below).
38 Finally, all EcoFlex “destination vectors” mentioned (pTU1, pTU2 and pTU3)
39 also contain a monomeric red fluorescence protein (RFP) gene pTU2^S-A, -a
40 and -b due to internal Bpil sites in RFP) under a LacI- and CAP-sensitive
41 promoter and strong RBS, sourced from the iGEM Registry of standard
42 biological parts (BBa_J04450). The RFP transcription unit is inserted between
43 flanking Bsal sites (for pTU1 and pTU3) or BsmBI sites (for pTU2) so that
44 negative colony-forming units (CFUs) can be visibly identified (red) after plate
45 growth.

52 53 **Promoter, RBS and terminator libraries – *in vivo* and *in vitro* validation**

54 A range of promoter and RBS strength variants were created by randomising
55 the *E. coli* σ^{70} Anderson promoter collection²⁶ and PET RBS Shine-Dalgarno
56 consensus sequences, respectively, upstream of a eGFP (hereafter referred
57 to as GFP) fluorescence reporter with flanking Bsal sites provided for
58
59
60

1
2
3 downstream Golden Gate Level 1 assembly (see SI text). We utilised the
4 iGEM Anderson promoters J23100, J23108 and J23114 as internal reference
5 standards. For the RBS library a 6 bp Shine-Dalgarno consensus sequence
6 AGGAGG was randomised to RRRRRR (A/G) to vary ribosome binding
7 strength and a range of low-high strengths are provided. The promoter and
8 RBS strengths in Level 1 context were characterised in the destination vector
9 pTU1-A with a constant J23100/SJM901 promoter (RBS library) or PET RBS
10 (promoter library), GFP and BBa_B0015 terminator. This was performed
11 using *E. coli* as a chassis with *in vivo* or *in vitro* (CFPS) fluorescence
12 measurements. Previously we have demonstrated a link between *in vivo* and
13 *in vitro* characterisation of promoter and RBS activity²⁷. Herein, we provide
14 further evidence of this relationship by characterising a wider range of
15 promoter (Figure 2A, -E), RBS (Figure 2B) and synthetic terminator parts
16 (Figure 2C, -D).
17
18
19
20
21

22 In summary, most of the parts behaved similarly between the two systems.
23 For example, a strong promoter or terminator *in vivo* was generally strong *in*
24 *vitro*. However, there are some exceptions to this general rule. For example,
25 *in vivo*, the SJM901 promoter variant showed a moderate GFP synthesis rate
26 of 1.2-fold in comparison to the J23100 promoter standard. Unexpectedly, *in*
27 *vitro*, this rate increased to 7.8-fold (Figure 2A, -E and -F). Whilst promoter
28 strengths demonstrated a clear link between *in vivo* and *in vitro* activity, we
29 observed some differences between RBS and terminator activity, which was
30 dependent on the strength of promoter used. Unlike *in vivo*, *in vitro*, the
31 signal-noise ratio for the J23100 promoter was low (Figure S4), thus it is
32 unclear to differentiate between weak-strong RBS variants. This could be
33 improved by using the strong SJM901 promoter (Figure S4). However, with
34 the SJM901 promoter the range of weak-strong RBS variants indicated from
35 *in vivo* observations was not as clear *in vitro*, whilst some variants showed
36 enhanced activity (TL2 and TL4) of almost 3-fold over the PET standard.
37 These findings could suggest that the strong activity of the SJM901 promoter
38 saturates ribosome binding *in vitro* therefore narrowing the range of observed
39 activities for apparent weak and strong RBS variants.
40
41
42
43
44
45

46 For terminator characterisation, a different assay was designed to quantify
47 terminator efficiency using EcoFlex parts. To do this, GFP was assembled
48 into pTU1-A with the J23100 or SJM901 promoter and PET RBS, followed by
49 a variable strength terminator. In pTU1-B, mCherry was assembled with the
50 weak J23114 promoter, PET RBS and BBa_B0015 terminator. These two
51 TUs were then assembled into pTU2-a as a Level 2 assembly (Figure S3). If
52 the variable terminator allowed read-through transcription, this was detected
53 by mCherry fluorescence. In comparison to the original publication describing
54 the synthetic terminator parts¹⁶ used herein, the simple assay we utilise
55 differs in the use of a strong constitutive promoter instead of the arabinose
56
57
58
59
60

1
2
3 induction system used previously¹⁶. We represent our data as a mCherry and
4 GFP rate that is normalised to a control plasmid containing two strong
5 BBa_B0015 terminators for both GFP and mCherry (Figure 2C, -D). Although
6 our data is not a direct comparison to Chen *et al*¹⁶, our *in vivo* measurements
7 suggest that the activity of the synthetic terminators is reproducible in the
8 EcoFlex context with either the SJM901 (Figure 2C) and J23100 promoters
9 (see SI files). It should also be noted that growth rate of the Level 2 plasmids
10 (chloramphenicol) is considerably slower than for the promoter and RBS
11 characterisation data, where Level 1 plasmids (carbenicillin) are used. The
12 standard error of the growth and GFP rates also increases significantly by
13 utilising the stronger SJM901, which is not apparent from the original Level 1
14 promoter characterisation. Interestingly, by using the J23100 promoter this
15 error decreases, suggesting that the SJM901 promoter causes more stress to
16 the cells in Level 2 plasmids. We utilised both promoters, since for cell-free
17 measurements, only the stronger SJM901 promoter was sufficient to drive
18 production of mCherry.
19
20
21
22
23

24
25 With the SJM901 promoter *in vivo*, the strongest terminators were L3S2P21
26 (0.37-fold mCherry rate), L3S1P51 (0.73-fold), L3S1P32 (1.26-fold) and
27 L3S1P11 (1.98-fold), each showing a low rate of mCherry fluorescence in
28 comparison to the strong BBa_B0015 terminator. The remaining library
29 members show a 3 to 10-fold increased mCherry fluorescence rate. The
30 signal intensity of GFP varied between the constructs but remained within a
31 2.5-fold range of the BBa_B0015 control plasmid. Interestingly, for all of the
32 strong terminators observed *in vivo*, these also behaved similarly *in vitro*
33 (Figure 2D). However, of the weaker terminators only L2U5H1 (2.88) and
34 BBa_B0012 (3.09) showed a clear increase in relative mCherry signal. We did
35 observe a broad range of activities, suggesting that small changes in the
36 terminator structure can have significant effects on either GFP or mCherry
37 production. Mechanisms outlined by Chen *et al*¹⁶ can include changes in
38 mRNA degradation, sequestering of the mCherry RBS site through complex
39 secondary structure or decreased translation coupling. Through continued
40 study and a broader in depth characterisation of DNA parts for EcoFlex, the
41 changes we have observed could be minimised by implementing the method
42 of Mutalik *et al*¹⁸ or introducing neutral insulator DNA sequences¹⁷⁻¹⁹ to
43 minimise complex mRNA secondary structure.
44
45
46
47
48
49

50 **N-terminal affinity tags for recombinant protein purification**

51 ORFs can be fused to a N-terminal fusion tag such as Strep(II) or His₆-tag for
52 recombinant protein production and purification. In addition, a combined T7
53 promoter, PET RBS, His₆-tag and thrombin cleavage site can be fused to an
54 ORF of interest, terminator and “destination vector” (e.g. pTU1-A-RFP) as a
55 four-part assembly and transformed directly into a lysogenic DE3 strain such
56 as BL21 Gold or KRX for IPTG-inducible T7-expression. Alternatively, lower
57
58
59
60

1
2
3 strength constitutive promoters can also be used to lower protein levels to
4 prevent aggregation and inclusion body formation, a problem often
5 encountered with T7-based expression²⁸. In summary, users can construct
6 TUs rapidly with the desired combinations of promoter strength, RBS variants,
7 N-terminal linkers, ORFs and terminator strength and conveniently identify
8 correctly assembled vectors using blue/white (LacZ) or red/white (RFP)
9 screening. Furthermore, for protein production, an ORF can be assembled
10 with EcoFlex, expressed and purified within 48 hours.
11
12

13
14 As an example, we sub-cloned CFP and mCherry into the pET15b vector
15 using the NdeI and BamHI restriction sites. As a comparison, the same genes
16 were MoClo assembled into pTU1-A with the combined T7 promoter, His₆-tag
17 and thrombin cleavage site, together with the BBa_B0015 terminator. We then
18 compared protein production and purification, using BL21 (DE3) Gold pLysS
19 as a host strain. In summary, in comparison to the pET15b expression
20 system, our plasmid system produces equivalent levels of the recombinant
21 His₆-tagged CFP and mCherry proteins, with a summary of the SDS-PAGE
22 purification of CFP and mCherry shown in Figure 3. To further demonstrate
23 this system, we also tested a variety of proteins (from our own library
24 collection) with this system showing high levels of production in the *E. coli*
25 KRX auto-induction strain (Figure S5, Table S4).
26
27
28
29
30

31 **Pooled library distribution of GFP and mCherry**

32 The assembly of random DNA part libraries for promoter, RBS, ORF and
33 terminator variants is a powerful technique to explore the design space for
34 constructing pathway combinations. Using pooled libraries of promoters and
35 RBS variants for GFP and mCherry in pTU1-A and pTU1-B, respectively,
36 these two TUs were randomly assembled into pTU2-a. Three separate
37 libraries for both GFP and mCherry, with either 3², 5² or 10² variants (for list of
38 parts see Table S4) for coupled promoter and RBS combinations, were built in
39 Level 1 plasmids, creating pTU1-A-GFP and pTU1-B-mCherry. These pooled
40 libraries were sequenced and combinations of pTU1-A-GFP and pTU1-B-
41 mCherry were assembled into pTU2-a, therefore creating theoretical library
42 sizes of 81 (3² variants of GFP combined with 3² variants of mCherry), 625 (5²
43 variants of GFP combined with 5² variants of mCherry) or 10,000 (10² variants
44 of GFP combined with 10² variants of mCherry). The libraries were analysed
45 by flow cytometry to determine the relative distribution of pathway variants
46 expressing GFP and mCherry. The fluorescence of GFP and mCherry Level 1
47 (Figure S7) and Level 2 libraries (Figure 4) was compared to individual Level
48 1 reference standards (Figure S7) prepared with the J23100, J23108 and
49 J23114 promoters, strong PET RBS and BBa_B0015 terminator, as well as
50 an empty vector control (pTU1-A-*lacZ* α). The population distributions of the
51 Level 1 and 2 libraries shifted in response to the diversity of the libraries
52 (Table S5) assembled in the MoClo reactions (Table S6). In general, an
53
54
55
56
57
58
59
60

1
2
3 increase in the diversity of the library from 3^2 , to 5^2 or 10^2 , resulted in an
4 increase in diversity for populations that were compared to the expression
5 profiles of the medium (J23108) and strong expression (J23100) profiles of
6 the GFP or mCherry standards. For instance, the population distributions of
7 Level 1 GFP libraries shifted towards an increase in the strong expression
8 profile (J23100-GFP) from 4.41% (3^2) towards 12.3% (5^2) and 11% (10^2) and
9 a marked decrease in the weak expression profile (J23114-GFP) from 70.9%
10 (3^2) decreasing to 64.1% (5^2) and 46.3% (10^2). Additionally, the Level 1
11 mCherry library profiles displayed an increased representation of the medium
12 (J23108-mCherry) expression from 35.7% (3^2) towards 45.1% (5^2) and 57.2%
13 (10^2), as the diversity of the library was increased.
14
15
16
17

18 Analysis of the Level 2 libraries has also shown that as the library diversity
19 was increased from 5^2 to 10^2 there was greater representation of populations
20 in the strong expression profiles of both J23100-GFP (5^2 : 0.68% to 10^2 :
21 4.59%) and J23100-mCherry (5^2 : 4.14% to 10^2 : 16.9%). The bias towards
22 low-expression in the smaller libraries is likely to occur during the overnight
23 growth phase during Level 1 MoClo assembly. *E. coli* transformed with pooled
24 libraries are likely to be subject to selection pressures in which those cells
25 transformed with weaker promoter and/or RBS combinations were less
26 burdened, in terms of their usage of cellular resources directed to GFP and/or
27 mCherry production, and thus grew more quickly than those cells producing
28 higher levels of the reporter proteins²⁹. As a result, the cells that had lower
29 rates of fluorescent reporter production were over represented in the final
30 population. We show that as the size of the library is increased there is likely
31 to be more cells transformed with a larger diversity of medium-to-strong
32 promoter and RBS strength combinations. Therefore, there was a greater
33 diversity of cells with different levels of cellular burden and thus a greater
34 representation of *E. coli* producing higher levels of fluorescent reporter
35 proteins in the final population. Whilst these selection biases exist, this type of
36 approach can provide a quality control check of the efficiency for EcoFlex
37 combinatorial assembly, using fluorescent reporter proteins to rationally enrich
38 library design.

46 **Violacein pathway optimisation with the secondary module**

47 Violacein is a violet pigment first isolated from *Chromobacterium violaceum*,
48 and the pathway belongs to the indolocarbazole biosynthetic family that
49 utilises L-tryptophan as a common precursor³⁰. We chose the violacein
50 pathway as a model pathway for EcoFlex combinatorial optimisation with the
51 secondary module, as it requires five enzymes (VioA, -B, -C, -D and -E)
52 encoded by the *C. violaceum* *vioABCDE* operon, with gene sizes ranging from
53 576 to 2997 bp and a total size of the synthetic operon of 7,242 bp. Herein,
54 we utilise the violacein pathway for optimisation as the violet colour produced
55 is a qualitative indication of pathway flux during library assembly³¹.
56
57
58
59
60

1
2
3
4 A major consideration for optimising combinatorial pathways is library size
5 and the limitations of the screening technique. Putting this into perspective,
6 depending on the assembly level and the number of parts included, Golden
7 Gate assemblies typically yield between 10^2 to 10^5 CFU per transformation.
8 Also, unlike the GFP and mCherry libraries described earlier, a significant
9 decrease in transformation efficiency (approximately 100-fold) is observed
10 with violacein pathway assembly. For example, during a five TU Level 2
11 assembly of the complete *vioABECD* pathway with the low-strength J23114
12 promoter, only 20-30 purple colonies were obtained from either JM109 or
13 KRX high efficiency (1×10^8 CFU per μg DNA) competent cells. Toxicity was
14 also noted during optimisation of violacein with VEGAS cloning in Brewer's
15 yeast¹³. To tackle this problem and provide an aid to debug pathway diversity
16 towards a more favourable design space, we decided to introduce a
17 secondary module site into the EcoFlex cloning scheme (Figure 1C). This
18 secondary module encodes two Bpil sites (see SI text), which provide
19 compatible overhangs (5' CTAT) and (3' GTAC) for transferring a sub-
20 pathway (or other DNA parts) from the Level 2 plasmids pTU2-A, -a, or -b
21 through Bsal digest, thus allowing entry of 2-5 TUs into the secondary site.
22
23
24
25
26
27

28
29 As an example, a constant sub-pathway for the *vioA* and *vioE* genes was
30 assembled into the RFP-containing pTU1-A and -B destination plasmids
31 respectively, with a J23114 promoter, PET RBS and BBa_B0015 terminator.
32 Next, the *vioA* and *vioE* TUs were assembled into pTU2-a, before sub-cloning
33 of this module by Bsal digest into the Bpil-linearized secondary module
34 plasmid pTU2^S-b, creating pTU2^S-*vioA-vioE*-b with either pMB1 (high-copy),
35 ColE1 (medium-copy) and p15A (low-copy) origins of replication. Next, pooled
36 promoter, RBS and terminator libraries of *vioB*, *vioC* and *vioD* were
37 assembled in pTU1-A-*lacZ* α , pTU1-B-*lacZ* α and pTU1-C-*lacZ* α respectively.
38 50 μL of the transformation mixture was plated onto carbenicillin agar to
39 estimate Level 1 efficiency using blue/white colony screening (>99%
40 efficiency), whilst the remaining mixture (~200 μL) was directly inoculated into
41 10 mL of LB medium (with carbenicillin) and grown overnight at 30 °C. The
42 library plasmid DNA was isolated, verified for homogeneity by restriction
43 digest and sequenced (Figure 5A). Level 1 promoter-RBS-terminator libraries
44 of *vioB*, *vioC* and *vioD* were then assembled into pTU2^S-*vioA-vioE*-b (pMB1,
45 ColE1 and p15A) using BsmBI and T4 DNA ligase. 5 μL of the reaction
46 mixture was then transformed into 50 μL of *E. coli* JM109 competent cells and
47 plated onto chloramphenicol plates and counted for CFUs (Figure 5B and
48 Table 1). We utilised JM109 instead of DH10 β as we have observed instability
49 issues with complex biosynthetic pathways with DH10 β . For example,
50 transformation of the lycopene or violacein pathway (pTU2-A-*vioABCDE* –
51 positive pathway control) yields a low percentage of white colonies, which
52
53
54
55
56
57
58
59
60

1
2
3 upon plasmid purification yields the same mini-prep restriction digest map as
4 the original plasmid. Whilst we did not pursue sequencing to identify potential
5 mutations, it is known that DH10 β has a high basal mutation frequency³².
6 With JM109 transformants, we observed a variety of violet, black, brown and
7 white CFU phenotypes (Table 1). Unlike the low-efficiency 5 TU *vioABCDE*
8 assembly, approximately 10²-10³ CFUs were obtained with the plasmids
9 containing the pMB1, ColE1 or p15A origins of replication (Table 1).
10
11

12
13 Initially, we assayed violacein production and sequenced the library parts
14 around each TU (*vioB*, *vioC* and *vioD*) in a few colonies from the library
15 transformation plate with pMB1 origin, and found that most of them contain a
16 mutated promoter or RBS in at least one of the *vioB*, *vioC* or *vioD* TUs after
17 overnight growth (see SI text and Figure S9-10). It is also interesting to note
18 that some of the clones after overnight liquid or plate growth lose their ability
19 to produce violacein, which is consistent with a mutation or recombination
20 event. To test whether this was linked to plasmid copy number, we also
21 screened colonies from the library transformation using also ColE1 (medium-
22 copy) and p15A (low-copy) origins of replication.
23
24
25
26

27 Focusing on the ColE1 and p15A plasmid variants, we re-streaked purple
28 colonies onto fresh plates and single colonies were then grown in biological
29 triplicate to semi-quantify crude violacein, whilst liquid culture aliquots were
30 sent for high-throughput 96-well sequencing (Bugs2Bases, Source
31 Bioscience) of the *vioB*, *vioC* and *vioD* library regions, which requires an
32 additional sub-culturing step before DNA purification and sequencing. For
33 ColE1 plasmid variants, only 5/11 clones were absent of mutations, whilst for
34 p15A clones, this increased to 9/11 clones. However, in the two p15A clones
35 that did contain a mutation (L32 *vioC* RBS and L40 *vioD* promoter), these
36 were single base-pair deletions immediately adjacent to the MoClo fusion site
37 and could be derived from initial Level 1 assembly (Figure S13). In addition
38 the sequencing trace of the L32 *vioD* terminator was weak, despite repeat
39 sequencing. The impact of the violacein pathway as a strong negative-
40 selection marker also appears to amplify the frequency of these mutation
41 events. Golden Gate and MoClo assembly is renowned to be highly efficient
42 and a restriction digest of DNA is generally considered acceptable for quality-
43 control checking³³. In contrast, the mutations found in pMB1 and ColE1
44 variants generally represent large-scale deletions (probable recombination
45 events), which form spontaneously during sub-culturing. We speculate that
46 these events are due to repetitive promoter, RBS and terminator sequences
47^{16,34} used during assembly and strong selection pressures caused by violacein
48 production. This is further supported by the fact that no mutations or deletions
49 were detected within the sequenced regions of the *vioB*, *vioC* and *vioD* ORFs,
50 thus mutations only seem to occur within the promoter, RBS or terminator
51 sequences. This provides a strong focal point for improvement in our future
52
53
54
55
56
57
58
59
60

1
2
3 studies of library design. Please see supporting information for a full summary
4 of these findings.
5
6

7 In general, the library colonies gave a wide range of crude violacein yields,
8 with the highest producing strain L15 giving $66.3 \pm 5.6 \text{ mg L}^{-1}$ and the lowest
9 strain L21 giving $3.6 \pm 1.7 \text{ mg L}^{-1}$ (Figure 5D). However, the ColE1 positive
10 control strain (with all violacein genes under J23114 promoter, PET RBS and
11 Bba_B0015 terminator) had the highest crude violacein yield at $69.1 \pm 7.4 \text{ mg}$
12 L^{-1} , whereas the equivalent p15A positive control strain produced $9.9 \pm 1.3 \text{ mg}$
13 L^{-1} , the lowest among the p15A library strains (Figure 5). From the
14 sequencing information, the ColE1 and p15A libraries are predominated by
15 weak-medium strength promoters and a range of RBS combinations.
16 Interestingly, the strongest promoter library member SJM901 appears in two
17 instances with *violC*, but it is only found in the p15A variants. It should also be
18 noted that when violacein production was previously optimised with
19 ePathOptimize using five engineered variants of the T7 promoter, all strong
20 producing clones (up to 60-240 mg L^{-1} crude violacein) were predominated by
21 combinations of the weakest T7 promoter variant³⁵. Although our study only
22 uses constitutive promoters, the frequent occurrence of weak promoters with
23 strong pathway variants is a shared common theme between these two
24 studies. Fine-tuning of violacein flux was also recently examined by rationally
25 minimising library size of RBS sites in a recent study³⁶.
26
27
28
29
30
31

32 For the terminators, there was a strong bias towards the L3S2P21, L2U5H08,
33 L2U2H08 and Bba_B0015 members with only a single occurrence of
34 Bba_B0012. Considering all variants of the EcoFlex library are included at
35 approximately the same concentration at the initial Level 1 assembly, it is
36 unclear why certain terminators become more frequent at the final stage of
37 selection of violacein CFUs.
38
39
40

41 **Future perspectives and conclusions**

42 While the EcoFlex kit is primarily designed for *E. coli*, we are also interested in
43 expanding this toolkit towards a universal cloning system between alternative
44 prokaryotic hosts that offer attractive advantages in biotechnology, such as
45 thermophilic growth, utilisation of alternative carbon feedstocks, resistance to
46 growth-inhibitory metabolites and high titre natural product synthesis. For
47 example, a pathway design could be studied in a non-traditional host and an
48 individual gene from the same pathway could then be rapidly swapped into *E.*
49 *coli* for enzyme or structural studies. Furthermore, whilst we demonstrate that
50 the secondary module can be used for the optimisation of biosynthetic
51 pathways, this feature could also be used for constructing novel shuttle
52 vectors or genome engineering tools. EcoFlex provides a foundation for the
53 design and implementation of a universal cloning system as we look towards
54 arcane chassis³⁷, which are becoming increasingly important for future
55
56
57
58
59
60

1
2
3 synthetic biology directions. In summary, the EcoFlex kit provides a simplified
4 cloning scheme that can be used for a variety of synthetic biology applications
5 for *E. coli* and in the future alternative prokaryotic host systems.

Materials and Methods

Bacterial strains and growth

Routine bacterial growth was performed at 37 °C in LB broth, with agar (15 g L⁻¹), carbenicillin (100 µg mL⁻¹), kanamycin (50 µg mL⁻¹) or chloramphenicol (35 µg mL⁻¹) as needed. Chemically competent *E. coli* DH10β (NEB), JM109 (Promega) and KRX (Promega) were used for routine transformations and maintenance of plasmids.

Molecular biology

Restriction enzymes (NEB), T4 polynucleotide kinase (NEB), T4 DNA ligase (Promega), Phusion[®] (Agilent) and Q5 DNA polymerase[®] (NEB) were used for routine cloning methods. Molecular biology kits were purchased from Qiagen (QIAprep Miniprep kit and QIAquick gel extraction kit). Primers and the *lacZα* fragment (see SI text) were synthesised by IDT. DNA parts and primer sequences are provided in the supplementary information. Routine and high-throughput Bugs2Bases DNA sequencing was performed by Source Bioscience, Cambridge.

EcoFlex assembly conditions

For Level 1 and 3 assembly, 100 ng of each DNA part was combined with 50 ng of destination plasmid and incubated with BsaI and T4 ligase for 15-30 cycles of 5 min at 37 °C and 10 min at 16 °C, followed by 5 min at 50 °C and 5 min at 80 °C. For Level 2 assembly, BsmBI was used as the type IIS restriction enzyme and the reaction was incubated at 37 °C overnight. 5 µL of Golden Gate reaction mix was transformed into 50 µL of chemically competent *E. coli* DH10β, JM109 or KRX cells using heat shock transformation. After recovery in 200 µL of SOC medium (NEB), 50-100 µL of cells were plated onto LB antibiotic plates and grown at 37 °C overnight. For assembly of Level 1 libraries, a pooled library of promoters or RBS (100 ng µL⁻¹) variants were assembled in a Level 1 assembly reaction and transformed into DH10β. Instead of incubating on plates, 200 µL of the SOC mixture was directly inoculated into 10 mL of 2YT medium with antibiotic and grown overnight at 30 °C and 160 rpm shaking. High purity library mini-preps was verified by restriction digest and sequencing.

Flow-cytometry

Golden gate combinatorial library reactions were transformed into *E. coli* and grown overnight in 1 ml 2YT and antibiotics at 30 °C. Cell populations were diluted into 1X phosphate buffered saline (2:1000) and loaded for detection into a S3e Cell sorter (Biorad, CA, USA). GFP detection (FL1 - Excitation 488 nm, Emission 525/30 nm) and mCherry detection (FL3 - Excitation 561 nm, Emission 615/25 nm) for approximately 48,000 cells per sample, was carried

1
2
3 out and analysed using FlowJo (v10.1r5) software (FlowJo, LLC, Oregon,
4 USA). In order to analyse the library populations, a gating strategy was used
5 in which reference regions were quantified. To do this, Level 1 plasmids were
6 prepared with either GFP or mCherry assembled with low (J23114), low-
7 medium (J23108) and high (J23100) promoter strengths, the PET RBS and
8 BBa_B0015 terminator. Single plasmid clones were transformed into DH10 β .
9 The distribution of library populations was then estimated by overlapping with
10 the known reference standards.
11
12

13 14 **Cell-free protein synthesis**

15 Based on the protocol from Sun *et al*³⁸, a cell-extract was prepared from *E.*
16 *coli* Rosetta (DE3) pLysS and reactions were monitored in a CLARIOStar $\text{\textcircled{C}}$
17 (BMG, Germany) plate reader. For full details, please see SI text and Table
18 S2.
19
20
21

22 ***in vivo* growth and fluorescence measurements**

23 Promoter, RBS and terminator parts were characterised in *E. coli* DH10 β .
24 Single colonies were picked in triplicate and grown overnight at 30 °C in a 24-
25 well plate in 2 mL of 2YT medium with antibiotics. Cell density was measured
26 in a CLARIOStar $\text{\textcircled{C}}$ plate reader at 600 nm and cells were sub-cultured into
27 100 μ L of 2YT with antibiotics in a 96-well Greiner plate to a starting OD₆₀₀ of
28 0.05. Plates were sealed with a Breathe-Easy $\text{\textcircled{R}}$ membrane (Sigma) and grown
29 at 30 °C for 6-12 hours at 600 rpm. OD₆₀₀, GFP and mCherry measurements
30 were recorded every 10 min (see SI text). Data analysis of characterisation
31 data was quantified as described previously with one modification²⁷. Rates of
32 GFP and mCherry production were quantified during exponential phase from
33 an average of triplicate data over a 1 hour time period. For cell-free activity
34 measurements only, mCherry fluorescence accumulates significantly later
35 than GFP and was measured at a different time point.
36
37
38
39
40

41 **Protein production and purification**

42 Plasmids (pET15b or EcoFlex) were transformed into BL21 Gold (DE3)
43 pLysS. A 10 mL 2YT overnight culture with antibiotics was grown overnight
44 and 0.5 mL was sub-cultured into 100 mL 2YT and grown at 37 °C, 200 rpm
45 until an OD₆₀₀ of 1.0 was reached. IPTG (0.4 mM) was added and the culture
46 was left for 16 hours at 19 °C, 200 rpm. Gravity flow immobilized metal ion
47 chromatography (IMAC) purification was performed. Please see SI text for
48 further details.

Figure legends

Figure 1. EcoFlex assembly. (A) Level 0 parts are held in pBP (bioparts – promoters, RBS, tags and terminators) and pBP-ORF (open reading frames) plasmids and assembled with BsaI and T4 DNA ligase into pTU1 destination plasmids (A, -B, -C, -D or -D₁, -E) forming Level 1 TUs. Genes are cloned with NdeI (5') and BamHI (3'), with the NdeI site providing an overlap between the start codon and RBS fusion site (CATA). Alternatively, if these sites are located within the gene, custom designed BsaI primers are used. Level 2 modules (2-5 TUs) were assembled with BsmBI and T4 DNA ligase into pTU2 plasmids, which were modified to provide flexibility for assembling 3-5 TUs into a module. In addition, Level 3 pathways (up to 20 TUs) can be assembled from compatible Level 2 modules into pTU3-A or pTU3-B using BsaI and T4 DNA ligase. (B) Assembly options (i) for purification tags and promoter choice, (ii) fusion site sequences and positions for Level 1 assembly of TUs. (C) Secondary module cloning for optimising library screening and minimising pathway variation. Table details compatible fusion sites and assembly options.

Figure 2 – Part characterisation *in vitro* and *in vivo*. A select range of promoters (A), RBS (B) and terminator variants (C) were tested for relative activity in *E. coli* DH10 β and cell-free protein synthesis. The J23100 and PET RBS were used for normalisation of promoter and RBS data, respectively. For the terminator assay (Level 2 plasmids), GFP was assembled with a SJM901 promoter, PET RBS and a variable strength terminator. This was followed by a weak J23114 promoter, PET RBS, mCherry and BBa_B0015 terminator. Data is represented as normalised relative activity of GFP and mCherry, respectively. (D) The Sigma70 promoter library characterisation using cell-free protein synthesis. Inset picture shows visual GFP production from cell-free extracts with the SJM901 promoter in comparison to J23100.

Figure 3 – T7 protein production and His₆-tag purification of mCherry and CFP. *E. coli* BL21 Gold (DE3) plasmids strains were grown at 37°C and induced with 0.4 mM IPTG overnight at 19°C. Recombinant proteins were purified using IMAC gravity-flow resin and washed with increasing concentrations of imidazole. Figure abbreviations are as follows, M – protein marker, S – soluble extract, I – insoluble proteins and EF – elution fraction.

Figure 4 – Flow cytometry of GFP and mCherry pooled promoter and RBS libraries. Mixed promoter, RBS libraries were assembled with GFP and mCherry into pTU1-A and pTU1-B, respectively. Instead of picking single colonies, plasmid DNA was prepared directly from liquid culture, checked for purity by restriction digest and sequencing. Level 1 GFP and mCherry libraries were then assembled into pTU2-a and transformed into DH10 β . Library cultures of Level 1 (Figure S7) and Level 2 were analysed by flow-cytometry using J23100, J23108 and J23114 promoter standards of GFP (labelled as G100, G108 and G114) and mCherry (labelled as C100, C108 and C114) as a reference of relative strength to estimate population distribution in both 3² (9 variants), 5² (25 variants) and 10² (100 variants) promoter-RBS combinations. These analyses are representative of ~48,000

1
2
3 cells per sample and these data were analysed using FlowJo (v10.1r5)
4 software.
5

6
7 **Figure 5 – Secondary module optimisation: Violacein pathway assembly.**

8 (A) The *vioA* and *vioE* genes were assembled with the J23114 promoter, PET
9 RBS and Bba_B0015 terminator in pTU1-A and pTU1-B, respectively and
10 then joined together in pTU2-a. The *vioA-vioE* fragment was sub-cloned by
11 BsaI into Bpil digested pTU2^S-b to form a *vioA-vioE* secondary module. Level
12 1 promoter-RBS-terminator libraries of *vioB* (pTU1-A), *vioC* (pTU1-B) and
13 *vioD* (pTU1-C) were then assembled. Inset sequencing trace demonstrates
14 purity of the library. Library mixtures (pMB1, ColE1 and p15A backbones)
15 were assembled into pTU2^S-*vioA-vioE*-b to complete the pathway. (B) 5 μ L of
16 assembly mixture was then transformed into 50 μ L JM109 competent cells
17 then grown overnight at 37 °C on 2YT and chloramphenicol plates. A range of
18 white, brown, light purple and dark purple coloured colonies were obtained
19 (Table 1). Some of the white colonies developed a pale purple shade after a
20 further day of growth at 30°C. (C) A selection ColE1 and p15A variants (in as
21 a triplicate biological repeat) were grown in 5 mL of 2YT liquid culture for high-
22 throughput Bugs2Bases sequencing (Source Bioscience). A number of
23 promoter-RBS regions with insertions are highlighted with an asterisk*. Crude
24 violacein content was estimated by UV-Vis as described ⁴⁰. PC, positive
25 control with all violacein genes under J23114 promoter, PET RBS and B0015
26 terminator. (D) Summary of sequencing results for p15A variants showing a
27 mixture of promoter-RBS and terminator combinations. For classification,
28 promoter, RBS and terminator are colour coded as strong, medium and weak
29 based on GFP and mCherry characterisation data. L32 *vioD* terminator could
30 not be identified, highlighted as a question mark. Asterisk indicates single
31 base-pair deletions in p15A library. For full sequencing results, please refer to
32 supporting information. Sequencing information is representative of a single
33 culture after additional growth step performed at Source Bioscience.
