Just Accepted

"Just Accepted" manuscripts have been peer-reviewed and accepted for publication. They are posted online prior to technical editing, formatting for publication and author proofing. The American Chemical Society provides "Just Accepted" as a service to the research community to expedite the dissemination of scientific material as soon as possible after acceptance. "Just Accepted" manuscripts appear in full in PDF format accompanied by an HTML abstract. "Just Accepted" manuscripts have been fully peer reviewed, but should not be considered the official version of record. They are citable by the Digital Object Identifier (DOI®). "Just Accepted" is an optional service offered to authors. Therefore, the "Just Accepted" Web site may not include all articles that will be published in the journal. After a manuscript is technically edited and formatted, it will be removed from the "Just Accepted" Web site and published as an ASAP article. Note that technical editing may introduce minor changes to the manuscript text and/or graphics which could affect content, and all legal disclaimers and ethical guidelines that apply to the journal pertain. ACS cannot be held responsible for errors or consequences arising from the use of information contained in these "Just Accepted" manuscripts.

1 Abstract

2 To investigate key taste-active components in Takifugu obscurus (T. obscurus), 3 twenty-eight putative taste compounds in cooked muscle of T. obscurus were quantitatively analyzed and the pivotal components were identified by taste 4 reconstitution, omission and addition tests. Moreover, the role of flavor peptides in 5 6 overall taste profile of T. obscurus were evaluated. Sensory evaluation revealed that 7 glutamic acid, serine, proline, arginine, lysine, adenosine-5'-monophosphate, inosine-5'-monophosphate (IMP), succinic acid, sodium, potassium, phosphates and 8 9 chlorides, were the core taste-active contributors to T. obscurus. Besides glutamic acid, IMP, succinic acid and potassium, the characteristic T. obscurus-like umami and 10 11 kokumi profiles were induced by adding flavor peptides, among which Pro-Val-Ala-Arg-Met-Cys-Arg Tyr-Gly-Gly-Thr-Pro-Pro-Phe-Val 12 and were 13 identified as key substances on the basis of addition test and dose-response analysis. 14 The present data may help to reveal the secret of delicious taste of T. obscurus and provide the basis for development of deeper flavor analysis of pufferfish. 15

25 Introduction

Due to its extremely delicious taste, pufferfish is very popular in Eastern Asia, 26 27 especially in China and Japan.¹ China is the largest supplier of pufferfish and around 70% of the annual catch are exported overseas.² T. obscurus, the most commonly 28 29 consumed pufferfish in China, was had a great market since a legal edible policy was opened in 2016.³ In particular, umami and kokumi taste characteristics of *T. obscurus* 30 31 are highly desirable. It can generate palatable, savory, rich continuity, complexity, and 32 palatability.^{4,5} Among the non-volatile taste-active compounds, free amino acids, 33 5'-nucleotides, organic acids, organic bases, inorganic ions and flavor peptides, were reported as the contributors to unique taste of raw as well as cooked meat of 34 pufferfish.^{1,4-6} 35 Sodium, potassium, glycine, alanine, arginine, adenosine-5'-monophosphate (AMP), guanosine-5'-monophosphate (GMP) and 36 37 inosine-5'-monophosphate (IMP) have been identified as key substances determining the typical umami taste of pufferfish.⁴ However, the multiple typical taste compounds 38 reported above so far are contradictory in T. obscurus. Lately, our research group has 39 40 also identified several flavor peptides originated from T. obscurus by using a series of sensory-guided separation and purification technology processes.^{5,6} However, their 41 sensory impact and contribution on overall taste profile in *T. obscurus* remain largely 42 43 unclear.

44 Due to complex interactions in foodstuffs, it is difficult to reveal the contribution of 45 each flavor compounds only through quantitative analysis and individual flavor 46 characteristics study.^{7,8} The omission experiment, known as removing an individual or

a group of compounds from a mixture content to measure the sensory effect on its
taste profile, has bridged the gap between physicochemical analysis and sensory data.⁹
Furthermore, complex relationships such as synergistic or masking effects among
components can be simplified by omission test, thus allowing a full analysis of the
taste contribution of the food extract studied.⁸ This method has been widely used to
figure out the key taste-active components in food, such as the Yangtze *Coilia ectenes*, crustaceans, the oval squid, tea, tomato and so on.^{10,11,12-15}

Based on the above sensory technique, to answer the puzzling question as to which 54 55 key taste compounds are responsible for the characteristic taste as well as the role of flavor peptides in overall taste profile of T. obscurus precisely, the objectives of the 56 present work were (I) to quantitate the putative taste-active compounds in boiled 57 58 muscle of T. obscurus; (II) to identify the key taste contributors and validate their sensory profile by taste reconstitution, omission and addition tests; and finally, (III) to 59 perform dose-response analysis in a simplified taste recombinant to evaluate the taste 60 61 contribution of flavor peptides in T. obscurus.

62 Materials and Methods

63 Chemicals. AMP (\geq 99%), GMP (\geq 99%), IMP (\geq 99%), free amino acids [aspartic

- 64 acid (\geq 99%), glutamic acid (\geq 99%), serine (\geq 99%), glycine (\geq 99%), threonine (\geq
- 65 98%), alanine (\geq 99%), proline (\geq 99%), arginine (\geq 99.5%), lysine (\geq 98%), valine (\geq
- 66 98%), histidine (\geq 99%), tyrosine (\geq 98%), phenylalanine (\geq 99%), isoleucine (\geq
- 67 98%), leucine (\geq 98%), cysteine (\geq 97%), methionine (\geq 98%)], betaine (\geq 99%),
- trimethylamine N-oxide dihydrate (TMAO, \geq 99%), trimethylamine (TMA, \geq 98%),

69	succinic acid (\geq 99.5%) and lactic acid (\geq 98%) (Sigma-Aldrich Corp., Shanghai,
70	China); titanium chloride (TiCl ₃), trichloroacetic acid (TCA), Reinecke's salt and
71	acetone (Sinopharm Chemical Reagent Corp., Ltd., Shanghai, China); methanol and
72	acetonitrile used for chromatography are HPLC grade (ANPEL Laboratory
73	Technologies Inc., Shanghai, China); the standards of sensory analysis, NaCl (\geq
74	99%), monosodium glutamate (MSG, \geq 99%)), sucrose (\geq 99%) and citric acid (\geq
75	99%), were purchased from Sigma-Aldrich Corp (Shanghai, China) while quinine
76	sulfate (\geq 98%) was obtained from Shanghai Yuanye Bio-Technology Corp., Ltd.
77	(Shanghai, China); four flavor peptides, Arg-Pro-Leu-Gly-Asn-Cys (RC-6),
78	Pro-Val-Ala-Arg-Met-Cys-Arg (PR-7), Tyr-Gly-Gly-Thr-Pro-Pro-Phe-Val (YV-8)
79	and Tyr-Lys-Cys-Lys-Asp-Gly-Asp-Leu-Arg (YR-9), which the information of amino
80	acid sequence were originated from our group's previous study, were synthesized by
81	GL Bio-Chem Corp., Ltd. (Shanghai, China). ^{5,6} The nominal purity of all peptides is
82	higher than 98.5% (w/w, the company's Test Reports, SHIMADZU LCMS-2010EV,
83	Kromasil C18, 250 \times 4.6 mm, 5 μm). Ultrapure water used for chromatography and
84	sensory evaluation was prepared by a Milli-Q® Reference System (MERCK
85	MILLIPORE, Darmstadt, Germany).

Materials. Twenty bred *T. obscurus* at two years old were purchased from Dalian
Tianzheng Industrial Co., Ltd (Liaoning Province, China). After being caught, *T. obscurus* were slaughtered by professional pufferfish operators according to The
National Standard Method of China (SC/T 3033-2016), then the dorsal muscle was
transported under ice in insulated polystyrene boxes to the laboratory by air transport

91 (no more than 4 h). Once in the lab, the meat was packaged in aluminum foil bag and
92 stored at -71 °C until further analysis.

93 **Preparation of taste extract.** *T. obscurus* muscle extract was prepared according to a process previously described.⁵ Frozen muscle fillets were thawed at 4 °C overnight. 94 95 As shown in Figure 1, 200 g minced meat was mixed with 800 mL of ultrapure water 96 and homogenized at 3 ×1,000 rpm for 2 min with an Ultra Turrax homogenizer (IKA Co., Germany). The homogenate was heated in a 100 °C ultrapure water bath for 3 h 97 prior to filtration through a Whatman.No.54 filter membrane.⁵ The cooled filtrate 98 (20 °C) was centrifuged (H1850R, Cence[®], China) at 10,000 rpm for 20 min at 4 °C. 99 100 The supernatant (natural extract) was collected and used directly for the quantitative 101 analysis. The natural extract was diluted with ultrapure water at the ratio of 2:1 (ν/ν), 102 and kept maximum 2 h before sensory evaluation (25 °C).

103 **Quantitative analysis**

Quantitation of free amino acids. Free amino acids quantitation was determined by 104 using the method developed by Adeveye with some modification.¹⁶ The fat in T. 105 obscurus was lost during cooking process and filtered out, thus there is no defatting 106 step. The natural extract (10.00 g) was mixed with 15 mL of 0.1 M HCl under 107 108 ultrasonic extraction for 30 min and centrifuged at 10,000 rpm for 10 min at 4 °C. 10.00 mL of the above supernatant was pipetted into a 50 mL centrifuge tube and 109 10.00 mL of 10% (w/v) TCA solution was added and mixed. The solution was kept at 110 static stage for 1h to precipitate the potential protein in the sample, and then 111 centrifuged at 10,000 rpm for 10 min at 4 °C. The supernatant was collected and 112

adjusted to pH 2.0 (pH meter, Five Easy Plus, METTLER TOLEDO, Swiss) with 6 M
NaOH and filtered through 0.22 μm water-filter before analysis by amino acid
analyzer (L-8800, Hitachi Co., Tokyo, Japan).

Ouantitation of the 5'-nucleotides. 5'-nucleotides were quantitated by HPLC 116 117 (Waters e2695, Waters, US) on a 250×4.6 mm, 5 µm, Inertsil ODS-3 column (GL, 118 Japan) using gradient elution with methanol as buffer A and 20.0 mM $KH_2PO_4-K_2HPO_4$ (v/v=1:1, pH 5.8) as buffer B at a flow rate of 1 mL/min.¹⁷ The 119 gradient was carried out as following, initial of 0% A for 6 min, linear change to 8% 120 121 A for 9 min, linear change to 35% A for 5 min, keep for 2 min, linear change to 0% A for 2 min and finally keep for 6 min. The effluent was monitored at 254 nm by a UV 122 detector (Waters 2998 PAD, Waters, US). All analyses were done in triplicate (n=3). 123 124 The identity and quantity of the nucleotides were determined by comparison with the retention times and peak areas of each 5'-nucleotides standard solution (AMP and 125 GMP respectively: 2.5, 5, 10, 15, 20, 50 mg/100 mL; IMP: 5, 10, 25, 50, 100, 200 126 mg/100 mL). Specific quantitative parameters are shown in Table S1 of 127 Supplementary Information. 128

Quantitation of organic acids. As for the contents of succinic acid and lactic acid, the natural extract was filtered by 0.45 μ m filters prior to HPLC analysis.¹⁸ The HPLC and column were the same as described in *Quantitation of the 5'-nucleotides*, while the eluting solvents consist of A (methanol) and B (0.05% phosphoric acid). The gradient elution program was as following: initial of 5% A for 10 min, linear change to 15% A for 5 min, linear change to 70% A for 6 min and finally linear change to 5%

A for 4 min. The samples were operated with a flow rate of 1.0 mL/min and monitored at 215 nm. All analyses were done in triplicate (n=3). Quantitative analysis was performed by comparing the peak areas of defined standard solutions (succinic acid: 5, 10, 20, 50, 100, 200 mg/100 mL; lactic acid: 25, 50, 100, 150, 200, 300 mg/100 mL). Specific quantitative parameters are shown in Table S1.

140 **Quantitation of organic bases.** The betaine present in the natural extract (50.00 g) was firstly crystallized and precipitated by Reinecke's salt under acidic conditions (pH 141 1, 12 M of HCl was used). Then the precipitate was dissolved with acetone/water 142 143 (70/30, v/v) and the content was quantitated based on colorimetry at 525 nm using UV-visible spectrophotometer (UV-2450, GL, Japan).¹⁹ The quantitation was 144 145 performed with a calibration curve, and the standard solution was 4, 8, 12, 16 and 20 146 mg/100 mL in ultrapure water. TMAO in the samples was reduced to TMA with TiCl₃ (1%, w/v) and detected by Gas Chromatography-Mass Spectrometry (GC-MS) 147 (Agilent 5977A, Agilent Technologies Inc., US).²⁰ The natural extract (25.00 g) was 148 mixed with 20.00 mL of 5% (w/v) TCA (extraction of TMA from the sample) and 149 centrifuged at 4,000 rpm for 5 min. 2.00 mL of the supernatant was poured into 20 150 mL headspace vial, and 5.00 mL of 50% (w/v) NaOH solution was added and 151 equilibrated 40 min at 40 °C before quantitation of TMA by GC-MS. Operating with 152 a flow rate of 1.0 mL/min, the following gradient was used for temperature program 153 of chromatography: starting 40 °C for 3 min, then increased to 220 °C at the rate of 154 30 °C/min, keeping 1 min. Using the electron ionization (EI), TMA was identified by 155 the retention time (RT), auxiliary qualifier ion (m/z 59 and m/z 42) and quantitative 156

157	ion (m/z 58), while quantitated via peak areas of standard substance $(1, 2, 5, 10, 20, $
158	40 mg/mL). The content of TMAO was calculated as the differences in TMA content
159	after and before reduction. ²⁰ Specific quantitative parameters are shown in Table S1.
160	Quantitation of inorganic ions. Sodium (Na ⁺) and potassium (K ⁺) content were
161	determined using flame atomic absorption spectrophotometry (ZEEnit 700, Analytik
162	Jena AG, Germany) according to the method of AOAC 2007. ²¹ The quantitation was
163	performed with a calibration curve, and the standard solutions for $Na^{\scriptscriptstyle +}$ and $K^{\scriptscriptstyle +}$ were
164	0.574, 0.985, 1.854, 3.076 and 4.010 mg/L as well as 0.481, 1.009, 2.022, 3.000 and
165	3.992 mg/L in ultrapure water, respectively. Phosphates (PO_4^{3-}) were estimated
166	following the conversion of molybdenum blue and quantitative analysis was carried
167	out by standard solution (0.08, 0.16, 0.24, 0.32, 0.40 mg/L). ²² Average quantitation of
168	chlorides (Cl ⁻) was measured according the modified method of Carpenter–Volhard. ²³
169	Specific quantitative parameters are shown in Table S1.

170 Sensory evaluation

General conditions. All the sensory experiments were performed in an 171 172 air-conditioned sensory lab (25 °C) with suitable ventilation and white light (ISO 8589:2007 E). Fourteen internal panelists (12 females and 2 males, aged from 20 to 173 26), who had no taste disorders and had half year experience of sensory evaluation, 174 175 participated in the study after signing consent forms. Nose clips were used to prevent potential interactions with olfactory. The temperature of the samples (poured into 176 plastic cups coded with three random numbers) and mouthwash (ultrapure water) was 177 178 constant at 25 °C. During evaluation, the panelist placed about 10 mL sample into mouth, held in mouth for 10 s and then spitted out. Ultrapure water was used for
mouth rinsing, in case of any aftertaste. Panelist would take a at least 30 s rest, before
evaluating the next sample.

Training sessions. Fourteen panelists were trained during 15 one-hour sessions to 182 183 learn how to recognize and quantitate the five basic tastes, kokumi and complex 184 situation according to a series of sensory approaches. Firstly, they were trained on five basic tastes to evaluate the aqueous solutions of the following standards in ultrapure 185 water: citric acid (0.430 mg/mL), sucrose (5.76 mg/mL), quinine sulfate (0.0325 186 187 mg/mL), NaCl (1.19 mg/mL) and MSG (0.595 mg/mL) for sourness, sweetness, bitterness, saltiness and umami, respectively. Then triangle tests were used to 188 establish the panels' sensitivity of each basic taste at lower concentrations than the 189 190 above five corresponding standards. Kokumi activity was trained according to the method of Meyer et al. and glutathione (5.0 mM, GSH) was used in this process.¹¹ 191 Finally, the panelists were trained to rate umami according to a scale composed by 192 different concentrations of MSG (0.24, 0.34, 0.49, 0.70 and 1.00 mg/mL). For 193 experiments with reference sample, the intensities of standard solution using for 194 reference were discussed and agreed within the panel. Then they were trained using 195 standard solutions and asked to memorize its intensity corresponding. The test didn't 196 perform until the panelists' data at stabilized level. 197

198 Sensory experiments

Taste profile analysis. Five samples were presented to the panelists, including (1) a
freshly prepared natural extract, (2) complete taste recombinant (CTR), (3) simplified

201	taste recombinant (STR), (4) CTR and (5) STR with 20.0 mg/100 mL of four flavor
202	peptides (RC-6, PR-7, YV-8 and YR-9), respectively. They were asked to scale the
203	intensity of attributes (sourness, sweetness, bitterness, saltiness, umami and kokumi)
204	on a five-point rating scale from 0 to 4 (0, no perceived; 1, weak; 2, average; 3, strong
205	and 4, extremely strong). ¹⁴ Intensity of ultrapure water was set as point 0. citric acid
206	(0.430 mg/mL), sucrose (5.76 mg/mL), quinine sulfate (0.0325 mg/mL), NaCl (1.19
207	mg/mL), MSG (0.595 mg/mL), and GSH (5 mM) were set as point 4 for the five basic
208	tastes and kokumi. Among them, a CTR was prepared according to the following
209	detail: taste compounds range from group I to V (Table 1) were dissolved in ultrapure
210	water in their natural concentrations and diluted with ultrapure water at 2:1 (v/v) to
211	reduce fatigue of the panelists. Then the pH of the solution was adjusted to 6.4 (pH of
212	the original natural extract under the same dilution fold) by KOH or HCl (0.1 mM).
213	For the experiments listed below, all the taste recombinants were diluted 1.5 times by
214	volume and the pH were regulated at 6.4 unless otherwise specified.
215	Omission test. 30 incomplete taste reconstitutions were prepared by omitting single

groups or individual taste compounds one by one from the CTR (Table 1). Each of 30 solutions was presented to the panelists who were asked to identify one stimulus out of three (1 incomplete taste reconstitution & 2 CTRs) that is different from the other two by using triangle test.^{12,24} The panelists who judged correctly were required to describe the perceived differences in comparison to the CTRs and rate the taste attributes on a five-rating scale as described in *taste profile analysis*.

Addition test. A model solution consisting of 12 taste-active compounds which were

identified by the omission test (refer to *Addition test* in *Results and Discussion*) was prepared firstly, then the 15 components judged as no taste contribution (Table S3) were added to the model solution one by one in their natural concentrations. Each of the sample was presented to the panelists in comparison with two model solutions using a triangle test as mentioned above.

228 **Dose-response analysis.** A STR (refer to Addition test in Results and Discussion) with 20.0 mg/100 mL of PR-7 or YV-8 was prepared as the reference, and its intensity 229 230 of umami and kokumi was defined as 0. Then the samples were prepared by adding 231 PR-7 or YV-8 to a STR at increasing dose (5.0, 10.0, 20.0, 40.0, 80.0 mg/100 mL), respectively. The panelists were asked to taste the reference solution at first and then 232 233 to evaluate taste attribute (umami and kokumi) of the samples on an 8 cm 234 unstructured linear scale anchored from "suppress" (value -4) to "contribute" (value +4) based on the reference.¹⁰ 235

236 Statistical analysis

The quantitative data were given as averages \pm standard deviations (SDs) of three 237 independent replicates. All the sensory evaluations were repeated in triplicate, giving 238 239 a total of 42 responses in each attribute (14×3) . The significant difference (p < 0.05, p < 0.01 and p < 0.001) of the triangle tests were performed via a Criteria Table of 240 ISO 4120:2004(E) (Sensory analysis—Methodology—Triangle test).²⁴ ANOVA was 241 242 used to determine the difference of individual taste attributes between natural extract, CTR, STR, CTR and STR with 20.0 mg/100 mL of four flavor peptides at a 5% 243 significance level (p < 0.05) by SPSS (Version 17.0, SPSS Inc., Chicago, USA). 244

245 **Results and Discussion**

246 Quantitative analysis

247 To elucidate the dominant taste-active compounds and construct an artificial solution 248 imitating the natural extract taste, the contents of putative taste compounds needed to 249 be quantitatively determined in a fresh aqueous extract of *T. obscurus* at first. Besides, 250 taste activity values (TAVs) were used to obtain first insights into the taste impact of individual compound. The value was calculated as the ratio between the concentration 251 of compound and its taste threshold.^{25,26} As shown in Table 1, the concentrations of 252 253 all free amino acids in group I were found to be below their taste thresholds. Glutamic acid has a relatively higher TAV of 0.11, whereas TAVs of the others were less 0.1. 254 Among the 5'-nucleotides (group II), quantitative analysis revealed IMP as the 255 256 prominent umami 5'-nucleotide occurring in T. obscurus extract at concentrations of 103.66 ± 0.41 mg/100 mL. In contrast, the concentrations of AMP and GMP were 257 much lower (2.38 ± 0.09 and 5.96 ± 0.07 mg/100 mL, respectively). Simultaneously, 258 IMP has the highest TAV (4.41), followed by GMP (0.73) while AMP presented a 259 lower value (< 0.1). Group III and IV are composed of organic acids and organic 260 bases, respectively. Evaluation of the TAVs of these compounds revealed a rather 261 high value of lactic acid (3.55) and succinic acid (5.32), but much lower values for 262 betaine and TMAO (< 0.1). In group V, TAVs of Na⁺, K⁺ and Cl⁻ exceeded 1 except 263 PO₄³⁻ (Table 1). Therefore, IMP, lactic acid, succinic acid as well as Na⁺, K⁺ and Cl⁻ 264 may serve as potential taste contributors (TAVs > 1). Although the free amino acids 265 were far below their taste thresholds in water, they were found to enhance the umami 266

and sweet character as previously described by Chen et al. for crab meat at very low 267 concentrations.¹⁹ So the compounds in T. obscurus with a low TAV (< 1) could 268 269 contribute to taste even at the subthreshold concentration, and the results will be 270 further investigated in the below.

271

Taste profile analysis of *T. obscurus*

272 According to quantitative analysis, a complete taste recombinant (CTR) containing 273 the "natural" amounts of 28 taste compounds (Table 1) was prepared, and its taste profiles was compared with a freshly authentic aqueous extract of T. obscurus by the 274 275 five-point rating scale. The sensory data revealed the highest scores of 2.6 and 2.5 for 276 the intensity of umami and kokumi taste in natural extract, respectively. The saltiness 277 was observed with a somewhat lower intensity of 1.1 (Figure 2A). In comparison, the 278 taste attribute of sour, sweet and bitter were rated only with very low intensities 279 (0.3-0.5). Therefore, umami and kokumi were the main body taste characteristics of T. obscurus, then was slight salty while the other taste qualities were especially low and 280 could be neglected (Figure 2A). Simultaneously, the taste intensities of CTR were 281 similar to the natural extract (Figure 2B). Sweet and sour were identical to the 282 original, while the umami and kokumi taste just slightly lower intensity than authentic 283 aqueous extract of T. obscurus (p > 0.05, Table S2). The results confirmed that the 284 typical taste of the natural extract could be effectively reproduced by the 28 taste 285 compounds (Table 1). In other words, key taste components of T. obscurus muscle 286 287 have been successfully identified and quantitated.

Omission test 288

289	After completing taste profile analysis, omission tests were carried out to investigate
290	the taste contribution of group and individual component and reveal the key taste
291	substances from Table 1. The first step was group omission test (Table 2). With the
292	exception of group IV, significant taste difference was observed when group I, II, III
293	and V were omitted from the CTR. For example, an extremely significant ($p < 0.001$)
294	reduction of umami and kokumi perception was observed when group I (free amino
295	acids) was removed. Similarly, umami (p < 0.001) and kokumi (p < 0.05) perceptions
296	were significantly decreased with the exclusion of group II (5'-nucleotides) from the
297	CTR. These results were consistent with previous studies that free amino acids and
298	nucleotides mainly contributed to umami attribute. ^{10,27} Similar experiments with the
299	omission of group V (inorganic ions) led to a significant ($p < 0.01$) decrease of umami
300	and saltiness. As for group IV, betaine and TMAO have been previously reported in
301	some seafoods and contributed to sweet taste. ^{11,12} Whereas in this research, the taste
302	profile of T. obscurus were mainly umami and kokumi, and taste characteristics of
303	sweet was very low. Thus, the role of group IV (organic bases) in the taste of T .
304	obscurus could be neglected.

After identifying the groups responsible for the taste profile of *T. obscurus*, similar omission experiments were prepared by removing individual compound from group I, II, III and V to further reduce the numbers of components that contribute significantly to taste. In the group I (Table 2), the omission of glutamic acid led to a significant (p < 0.01) decrease of umami. Glutamic acid is an umami amino acid reported as a taste-active substance in many foods, such as the oval squid, Chinese mitten crab,

mushrooms, and tomato, etc.^{12,18,26,28,29} In the group II, only the omission of IMP led 311 to a total weakening of sour, salty, kokumi, and especially for umami (p < 0.05). The 312 313 overall acceptability and taste were declined distinctly in the absence of IMP. As such, IMP was a dominant taste-active compound in T. obscurus based on the sensory 314 315 results and determination of TAV. In group III, removing succinic acid resulted in a 316 significantly decrease of umami (p < 0.01), which is consistent with quantitative analysis (TAV > 1) and previous reports.^{26,30} In the group V, significant taste 317 differences (p < 0.01) were observed with the exclusion of the four inorganic ions 318 319 from the complete model mixture. Omission of K^+ led to a significant increase (p < 0.05) of sourness and a significant decrease of umami (p < 0.05). 320

321 Addition test

Combining the results of group and individual omission tests, 12 compounds (glutamic acid, serine, proline, arginine, lysine, AMP, IMP, succinic acid, Na⁺, K⁺, PO₄³⁻ and Cl⁻) were determined as the key taste-active compounds in *T. obscurus*. In order to avoid missing potential core components, addition tests were further implemented to determine whether associations of several components could have an unknown effect on one or more taste properties. However, none of the component was identified at the level of significance (p < 0.05) (Table S3).

Thus, a simplified taste recombinant (STR) containing the above 12 taste-active compounds was obtained according to the results of the omission and addition tests. In particular, glutamic acid, IMP, succinic acid and K⁺, significantly contribute to the umami perception in the taste recombinant of *T. obscurus* (p < 0.05, Table 2).

333	Combined with the results of TAVs, the seven compounds (except for IMP, succinic
334	acid, Na ⁺ , K ⁺ and Cl ⁻) were identified as the key taste compounds while their TAVs
335	were less than 1. This means those components induced the characteristic taste of T .
336	obscurus at subthreshold level. Although TAVs of lactic acid was higher than 1, it has
337	no significant contribution to the typic taste of T. obscurus by a series of sensory
338	evaluation. The reason could be that TAV is a useful value to evaluate the individual
339	taste component, while interaction of compounds in food context may be not taken
340	into consideration, such as synergy or masking effects. ³¹ Based on the above results,
341	the reported prominent taste components from aquatic products were summarized to
342	explore if there are the common key taste contributors in aquatic products and their
343	correlations with T. obscurus (Figure 3, the detail data was presented Table S4). 39
344	key taste compounds originated from fish, crustaceans, mollusk and Echinodermata
345	were found. Ten compounds including glutamic acid, glycine, alanine, arginine, IMP,
346	AMP, Na ⁺ , K ⁺ , Cl ⁻ and PO ₄ ³⁻ were commonly found in most aquatic products (Figure
347	3), and eight of them served as key contributors to <i>T. obscurus</i> . The results indicated
348	that most of the prominent components were similar in aquatic foodstuffs. Those
349	components constituted the basic taste profiles of aquatic foods, while the difference
350	in type of unique compounds and quantitation of shared substances lead to a specific
351	taste for each aquatic food. ^{11,12}
352	Since then, taste attributes between the CTR and STR were compared by the triangle

test and the five-rating scale as described before. Although a significant differencewas found in the single taste attributes through a five-rating scale (Table S2), where

355 umami and kokumi were stronger (P < 0.05) in the CTR, the two solutions could be scarcely discriminated (correct response = 20/42) on the overall taste. MSG-like 356 357 amino acids (aspartic acid and glutamic acid) and 5'-nucleotides, especially AMP, GMP and IMP, played a dominant role in umami taste, and the synergistic effects of 358 359 those compounds could further enhance umami-like taste, such as aspartic acid, 360 glutamic acid and IMP, sweet amino acids (serine, glycine and alanine) and IMP.^{27,32-34} The lower intensity of umami taste in the STR compared with CTR might 361 be due to the partial absence of those compounds and thus leading to a weaker 362 363 synergistic effect. Whereas the difference of CTR and STR could have other unknown compounds contributing towards kokumi, such as oligopeptides.^{11,35} This part will be 364 further investigated below. 365

366 Taste contribution of flavor peptides in *T. obscurus*

To figure out whether the flavor peptides contained in T. obscurus contribute to the 367 characteristic umami and kokumi taste of pufferfish, additional taste recombinants 368 were prepared by spiking four flavor peptides (RC-6, PR-7, YV-8 and YP-9) to the 369 CTR and STR, respectively. The four peptides were chosen for their prominent taste 370 371 of fishy, umami and kokumi during isolation and purification process (the detail taste characteristics of flavor peptides in *T. obscurus* is presented in Table S5).^{5,6} When the 372 four peptides were added to the CTR, a significant (p < 0.05) increase of umami and 373 kokumi perception was detected by a triangle test (Table 3). Moreover, taste profile 374 analysis of this recombinant presented increased intensities of umami $(2.3 \rightarrow 2.6)$ and 375 kokumi $(2.3 \rightarrow 2.5)$, which matched very well with the taste profile found in natural 376

extract (Figure 1D). Similarly, an approximate positive result was also observed in the
STR. The kokumi and umami intensity score was increased from 2.0 to 2.4 by adding
four peptides, respectively (Table S2), and was closer to the taste profile of natural
extract (Figure 1E). Therefore, the addition of four peptides mainly bridge the gap of
taste difference between the natural extract and artificial imitation recombinant of *T*. *obscurus*.

On this basis, omission tests were also carried out to narrow the prominent flavor peptides contribute to taste attribute in *T. obscurus*. Whether in CTR or STR, the omission of PR-7 and YV-8 led to a significant (p < 0.05) reductions in umami and kokumi taste (Table 4). However, there was no significant difference (p > 0.05) was perceived in both model systems when RC-6 and YP-9 were removed. As a result, it could be concluded that PR-7 and YV-8 were also the key taste-active compounds in *T. obscurus*.

Dose-response analysis. To further investigate the concentration effects of PR-7 and 390 YV-8 on umami and kokumi taste of T. obscurus, dose-response analysis was 391 performed. Positive correlation between the concentrations and umami & kokumi 392 intensity of two peptides were revealed (Figure 4). The Pearson correlation 393 coefficients (r) of umami and kokumi for PR-7 were 0.94 and 0.92, respectively, and 394 they are both 0.98 for YV-8. Therefore, the two flavor peptides have clear umami and 395 kokumi modulation in T. obscurus model solution. Due to peptides losing during 396 isolation and purification processes, the amounts of the four flavor peptides (RC-6, 397 PR-7, YV-8 and YP-9) in T. obscurus were unknown.⁵ Although the concentration 398

399 (20 mg/100 mL) of four flavor peptides in model solution may be inconsistent with 400 the "natural" concentrations, the results proved that flavor peptides were one of the 401 indispensable components in the characteristic taste for *T. obscurus*. Further research 402 will be necessary to quantitate the concentration of those peptides, so that their 403 contribution to the overall taste of *T. obscurus* could be rigorously elaborate.

404 Collectively, 12 compounds, glutamic acid, serine, proline, arginine, lysine, AMP, IMP, succinic acid, Na⁺, K⁺, PO₄³⁻ and Cl⁻ were identified as the key taste-active 405 components in T. obscurus. This was similar to the common prominent taste 406 407 contributors that have been found in aquatic products. More especially, two flavor peptides, PR-7 and YV-8 could significantly increase the typical umami and kokumi 408 409 taste characteristics of T. obscurus. The overall taste profile of T. obscurus can be 410 greatly reconstituted by those components. These results, therefore, help for a better understanding of the delicious mystery of T. obscurus taste and establish the 411 theoretical foundation for the further development of pufferfish flavor. 412

Figure 2. Taste attribute of natural and several taste recombinants of *T. obscurus*. A, taste profile of a freshly prepared natural extract; Black dotted line in B, C, D and E represented the taste intensity value which were standardized based on A (six taste attribute values of A were defined as "1"). B, the complete taste recombinant (CTR), containing 28 compounds (Table 1); C, a simplified taste recombinant (STR), containing 12 key taste-active components; D and E, a CTR and STR with four flavor peptides, respectively.

Figure 3. Key taste-active compounds that have been reported in 24 aquatic products. "24" is the result in this study while "1-23" is the literature reports. The 39 prominent components (free amino acids, 5'-nucleotides, organic acids, organic bases, inorganic ions and others) were obtained, which were originated from fish, crustaceans, mollusk and *Echinodermata*. Among them, glutamic acid, glycine, alanine, arginine, IMP, AMP as well as Na⁺, K⁺, Cl⁻ and PO₄³⁻ were commonly found in the above foodstuffs. Isoleucine was not contained.

Figure 4. Effects of addition of PR-7 (A) or YV-8 (B) at increased concentrations in a simplified taste recombinant (STR) on each taste attribute (umami and kokumi). Intensity of taste was evaluated by an 8 cm unstructured linear scale anchored from

"suppress" (value -4) to "contribute" (value 4), 0 referring to the taste intensity of standard solution (STR with 20 mg/100 mL PR-7 or YV-8). For each taste attribute, y-axis represents the amount of peptide added was 5.0, 10.0, 20.0, 40.0 and 80.0 mg/100 mL, respectively (bottom to up).

peptide	identification (n=42)	significance	(change in taste intensity)
CTR + peptide	25	***	U [↑] * (2.3 \rightarrow 2.6), K [↑] * (2.3 \rightarrow 2.5), So [↓] , Sa [↑]
STR + peptide	30	***	K ↑ ^{**} (2.0→2.4), U ↑ ^{**} (2.0→2.4), Sa [↑] , So [↑] ,

CTR + peptide, a taste recombinant was prepared by adding four flavor peptides (RC-6, PR-7, YV-8 and YP-9) to the complete taste recombinant (CTR) containing 28 taste compounds; STR + peptide, a taste recombinant was prepared by adding four flavor peptides to the simplified taste recombinant (STR) only containing 12 key taste-active compounds; So, sourness; S, sweetness; B, bitterness; Sa, saltiness; U, umami; K, kokumi; * p < 0.05; ** p < 0.01; *** p < 0.001.

Omission	NO. of correct	Level of	Degree of taste difference
component	identification (n=42)	significance	(change in taste intensity)
Complete taste recombinant			
RC-6	13	-	
PR-7	20	*	U↓* (2.6→2.4), K↓, Sa↑
YV-8	20	*	U↓, So↓, Sa↓, K↓
YR-9	13	-	
Simplified taste recombinant			
RC-6	18	-	
PR-7	21	*	K ↓ [*] (2.4→2.1), U↓, Sa↑
YV-8	20	*	K ↓* (2.4→2.2), U↓
YR-9	18	-	

Table 4 Influence of individual flavor peptide omission on the taste attributes of a complete and simplified taste recombinant.

So, sourness; S, sweetness; B, bitterness; Sa, saltiness; U, umami; K, kokumi; -, not

significant; * p < 0.05; ** p < 0.01; *** p < 0.001.
