During the last years carbon nanotubes have attracted a great interest of world scientists. Nowadays researchers study their properties, perform the experiment in the laboratories and develop a set of theories about their practical application.

Carbon nanotube is an elongated cylindrical structure with a diameter of one to several tens nanometers and a length of several centimeters, consisting of one or more rolled up into hexagonal graphite planes with generally hemispherical head. Nanotubes are members of the [fullerene](#) structural family. Their name is derived from their long, hollow structure with the walls formed by one-atom-thick sheets of carbon, called [graphene](#). These sheets are rolled at specific and discrete ("[chiral](#)") angles, and the combination of the rolling angle and radius decides the nanotube properties; for example, whether the individual nanotube shell is a [metal](#) or [semiconductor](#).

The intrinsic mechanical and transport properties of carbon nanotubes make them the ultimate carbon fibers. Thermal and electrical conductivity are also very high, and comparable to other conductive materials. Overall, carbon nanotubes show a unique combination of stiffness, strength, and tenacity compared to other fiber materials which usually lack one or more of these properties.

For example, scientists are trying to develop a theory about the construction of a cable for a space elevator: nanotubes can hold tremendous weight up to a ton per square millimeter. However, they can't receive long enough carbon tubes with a wall thickness of one atom. The filaments, woven from the relatively short nanotubes can be used, but they reduce the final strength.

One of the interesting applications of carbon nanotubes in future is the idea of creating the nonvolatile random access memory (NRAM). The silicon substrate is applied to thin insulating membrane of silicon oxide. The conductive electrodes (130 nm),

separated by insulating layers, are placed along the width of the membrane. Over electrodes are arranged nanotube arrays which are closed on both sides of the conductive contacts. In the normal state (state OFF) nanotubes do not touch the electrodes and are above them at a height of about 13 nm. If the voltage is applied to the lower electrode, the nanotube under the influence of an electric field will bend and touch the lower electrode. However, this state (state ON) is stable due to the balance between mechanical stress and Van der Waals forces. Thus, by varying the voltage on the electrode we will obtain two stable mechanical states of nanotubes, one of which has a contact with the electrode, and the other - no. One of these states will respond to a logical zero and the other - the logic unit. In order to read the contents of the memory cell it will be necessary to analyze its state. If the memory cell is in the state OFF, the electrical circuit is open and the voltage will be high, which corresponds to a logic one. If the memory cell is in the ON, i.e. there is contact between the nanotube and the lower electrode, the circuit is closed and the voltage is low, corresponding to logic zero.

In comparison with traditional memory types, NRAM memory has several advantages. First, despite the fact that this RAM-memory, it is volatile. Secondly, according to the company Nantero, the information recording density in the devices can reach NRAM 5 billion bits per square centimeter (several times greater than the current memory chips), and the memory operating frequency - to 2GHz.

The small dimensions, strength and the remarkable physical properties of these structures make carbon nanotube a very unique material with a whole range of promising applications in different areas. The usefulness of nanotubes is evident. However, the development and introduction of nanotubes into everyday life is complicated by a lack of knowledge, complexity and high cost of production.

Соціально-гуманітарні аспекти розвитку сучасного суспільства : матеріали IV Всеукраїнської наукової конференції викладачів, аспірантів, співробітників та студентів факультету іноземної філології та соціальних комунікацій, м.
