ABSTRACT. The main result we obtain is that given $\pi : N \rightarrow M$ a T^s -subbundle of the generalized Hopf fibration $\bar{\pi} : H^{2n+s} \rightarrow \mathbb{C}P^n$ over a Cauchy-Riemann product $i : M \subseteq \mathbb{C}P^n$, i.e. $j : N \subseteq H^{2n+s}$ is a diffeomorphism on fibres and $\bar{\pi} \circ j = i \circ \pi$, if s is even and N is a closed submanifold tangent to the structure vectors of the canonical \mathcal{R} -structure on H^{2n+s} then N is a Cauchy-Riemann submanifold whose Chen class is non-vanishing.

KEY WORDS AND PHRASES. Principal toroidal bundle, \mathcal{R} -manifold, generalized Hopf fibration, framed C.R. submanifold, characteristic form.

1980 MATHEMATICS SUBJECT CLASSIFICATION CODE: 53C40,53C55

1.- INTRODUCTION AND STATEMENT OF RESULTS.

As a tentative of unifying the concepts of complex and anti-invariant submanifolds of an almost Hermitian manifold, A. BEJANCU, [1], has introduced the notion of Cauchy-Riemann (C.R.) submanifold. This has soon proved to possess a largely rich number of geometrical properties; e.g. by a result of D.E.BLAIR & B. Y.CHEN, [2], any C.R. submanifold of a Hermitian manifold is a Cauchy-Riemann manifold, in the sense of A.ANDREOTTI & C.D.HILL, [3]. Let M^{2n+s} be a real $(2n+s)$ -dimensional manifold carrying a metrical f -structure $(f, \xi_a, \eta_a, \mathcal{O})$, $1 \leq a \leq s$, with complemented frames, cf. [4]. A submanifold $j : N \rightarrow M^{2n+s}$ is said to be a *framed C.R. submanifold* if it is tangent to each structure vector ξ_a of M^{2n+s} and it carries a pair of complementary (with respect to $G = j^* \mathcal{O}$) smooth distributions $\mathcal{D}, \mathcal{D}^\perp$ such that $f_x(\mathcal{D}_x) \subseteq \mathcal{D}_x$, $f_x(\mathcal{D}_x^\perp) \subseteq T_x(N)^\perp$, for all $x \in N$, where $T(N)^\perp \rightarrow N$ stands for the normal bundle of j . Cf. I.MIHAI, [5], L.ORNEA, [6]. Since f -structures are known to generalize both almost complex ($s=0$) structures and almost contact ($s=1$) structures, the notion of framed C.R. submanifold contains those of a C.R. submanifold (see e.g. [7], p.83) of an almost Hermitian manifold and of a

contact C.R. submanifold (see e.g. [7], p.48) of an almost contact metrical manifold.

Let $\bar{\pi} : H^{2n+s} \rightarrow \mathbb{C}P^n$ be the generalized Hopf fibration, as given by D.E.BLAIR, [8]. Leaving definitions momentarily aside we may formulate the following:

THEOREM A

- i) Let N be a framed C.R. submanifold of an \mathcal{S} -manifold M^{2n+s} . Then the f -anti-invariant distribution \mathcal{D}^\perp of N is completely integrable.
- ii) Any framed C.R. submanifold of H^{2n+s} , (carrying the standard \mathcal{S} -structure) is either a C.R. submanifold (s even) or a contact C.R. submanifold (s odd). The converse holds.
- iii) Let N be an f -invariant (i.e. $\mathcal{D}^\perp = (0)$) submanifold of H^{2n+s} . Then N is totally-geodesic if and only if it is an \mathcal{S} -manifold of constant f -sectional curvature $1 - \frac{3}{4}s$.
- iv) Any f -invariant submanifold of H^{2n+s} having a parallel second fundamental form is totally-geodesic.

It is known that compact regular contact manifolds are S^1 - principal fibre bundles over symplectic manifolds, cf. W.M. BOOTHBY & H.C.WANG, [9]. Eversince this (today classical) paper has been published, several "Boothby-Wang type" theorems have been established, cf. e.g. A.MORIMOTO, [10], for the case of normal almost contact manifolds, S.TANNO, [11], for contact manifolds in the non-compact case; more recently, we may cite a result of I.VAISMAN, [12], asserting that compact generalized Hopf manifolds with a regular Lee field may be fibred over Sasakian manifolds, etc.

There exists today a large literature, cf. K.YANO & M.KON, [7], concerned with the study of the geometry (of the second fundamental form) of a C.R. submanifold of a Kaehlerian ambient space. In particular, following the method of Riemannian fibre bundles (such as introduced by H.B.LAWSON, [13], towards studying submanifolds of complex space-forms, and developed successively by Y.MAEDA, [14], M.OKUMURA, [15]), K.YANO & M.KON, [16], have taken under study contact C.R. submanifolds of a Sasakian manifold M^{2n+1} (where M^{2n+1} is previously fibred over a Kaehlerian manifold M^{2n}) which are themselves S^1 -fibrations over C.R. submanifolds of M^{2n} .

The last piece of the mosaic we are going to mend is the concept of canonical cohomology class (here after referred to as the *Chen class*) of a C.R. submanifold. Cf. B.Y.CHEN, [17], with any C.R. submanifold M of a Kaehlerian manifold there may be associated a cohomology class $c(M) \in H^{2p}(M; \mathbb{R})$, where p stands for the complex dimension of the holomorphic distribution of M . Although the canonical Hermitian structure (cf. [18]) of H^{2n+s} is never Kaehlerian (cf. [8], p.174) we show that the Chen class of a C.R. submanifold may be constructed as well and obtain the following :

THEOREM B

Let $j : N \rightarrow H^{2n+s}$ be a closed (i.e. compact, orientable) submanifold tangent to the vector fields ξ_a , $1 \leq a \leq s$, of the canonical \mathcal{S} -structure on H^{2n+s} and assume there exists a T^s - principal bundle $\pi : N \rightarrow M$ over a Cauchy-

Riemann product $(M, \mathcal{D}, \mathcal{D}^\perp)$, $i : M \rightarrow \mathbb{C}P^n$, (\mathcal{D} is the holomorphic distribution), such that $\bar{\pi} \circ j = i \circ \pi$ and j is a diffeomorphism on fibres. If s is even then N is a C.R. submanifold whose totally-real foliation is normal to the characteristic field of H^{2n+s} and whose Chen class $c(N) \in H^{2p+s}(N; \mathbb{R})$, $p = \dim_{\mathbb{C}} \mathcal{D}$, is non-vanishing.

2.- NOTATIONS, CONVENTIONS AND BASIC FORMULAE.

Let M^{2n+s} be a real $(2n+s)$ -dimensional C^∞ -differentiable connected manifold. Let \underline{f} be an f -structure on M^{2n+s} , i.e. a $(1,1)$ -tensor field such that $\underline{f}^3 + \underline{f} = 0$ and $\text{rank}(\underline{f}) = 2n$ everywhere on M^{2n+s} , cf. K.YANO, [19]. Assume that \underline{f} has complemented frames, i.e. there exist the differential 1-forms η'_a and the dual vector fields ξ'_a on M^{2n+s} , i.e. $\eta'_a(\xi'_b) = \delta_{ab}$, $1 \leq a, b \leq s$, such that the following formulae hold:

$$\eta'_a \circ \underline{f} = 0, \quad \underline{f}(\xi'_a) = 0, \quad \underline{f}^2 = -I + \eta'_a \otimes \xi'^a. \tag{2.1}$$

Throughout, one adopts the convention $\eta'_a = \eta'^a$, $\xi'_a = \xi'^a$. The f -structure is normal if $[\underline{f}, \underline{f}] + (d\eta'_a) \otimes \xi'^a = 0$, where $[\underline{f}, \underline{f}]$ denotes the Nijenhuis torsion of \underline{f} , see e.g. H.NAKAGAWA, [20]. Let \mathcal{G} be a compatible Riemannian metric on M^{2n+s} , i.e. one satisfying:

$$\mathcal{G}(\underline{f}X, \underline{f}Y) = \mathcal{G}(X, Y) - \eta'_a(X) \eta'^a(Y). \tag{2.2}$$

Compatible metrics always exist, cf. D.E.BLAIR, [4]. Such $(\underline{f}, \xi'_a, \eta'_a, \mathcal{G})$ has often been called a *metrical f-structure with complemented frames*. Let $\underline{F}(X, Y) = \mathcal{G}(X, \underline{f}Y)$ be its *fundamental 2-form*. Throughout we assume M^{2n+s} to be an \mathcal{R} -manifold, cf. the terminology in [4], i.e. the given f -structure is

normal, its fundamental 2-form is closed and there exist s smooth real-valued functions $\alpha_a \in C^\infty(M^{2n+s})$, $1 \leq a \leq s$, such that:

$$d \eta'_a = \alpha_a \underline{F}. \tag{2.3}$$

We shall need, cf. [4], [21], the following result. Let M^{2n+s} , $n > 1$, be a connected manifold carrying the \mathcal{R} -structure $(\underline{f}, \xi'_a, \eta'_a, \mathcal{G})$, $1 \leq a \leq s$. Then α_a are real constants, ξ'_a are Killing vector fields (with respect to \mathcal{G}) and the following relations hold:

$$\underline{D}_X \xi'_a = -\frac{1}{2} \alpha_a \underline{f} X \tag{2.4}$$

$(\underline{D}_X \underline{f}) Y = \frac{1}{2} \alpha^a \{ [\mathcal{G}(X, Y) - \eta'_b(X) \eta'^b(Y)] \xi'_a - [X - \eta'_b(X) \xi'^b] \eta'_a(Y) \}$ (2.5) for any tangent vector fields X, Y on M^{2n+s} . Here \underline{D} denotes the Riemannian connection of (M^{2n+s}, \mathcal{G}) , and $\alpha^a = \alpha_a$, $1 \leq a \leq s$.

Let M^{2n+s} be an \mathcal{R} -manifold with the structure tensors $(\underline{f}, \xi'_a, \eta'_a, \mathcal{G})$. Let \mathcal{L} be the smooth s -distribution on M^{2n+s} spanned by ξ'_a , $1 \leq a \leq s$. By normality one has $[\xi'_a, \xi'_b] = 0$, i.e. \mathcal{L} is involutive. If both \mathcal{L} and the structure vector fields ξ'_a are regular (in the sense of R.PALAIS, [22]) then the \mathcal{R} -structure itself is termed *regular*. We shall need the main result of D.E. BLAIR & G.D.LUDDEN & K.YANO, ([21], p.175). That is, let M^{2n+s} be a compact connected $(2n+s)$ -dimensional, $n > 1$, \mathcal{R} -manifold; then there is a T^s -principal fibre bundle $\bar{\pi} : M^{2n+s} \rightarrow M^{2n} = M^{2n+s} / \mathcal{L}$ and M^{2n} is a Kachlerian

manifold. Here M^{2n} denotes the leaf space of the s -dimensional foliation $\tilde{\pi}$ and T^s is the s -torus. Also, cf. ([21], p.178), $\gamma = (\eta'_1, \dots, \eta'_s)$ is a connection 1-form in $M^{2n+s}(M^{2n}, \tilde{\pi}, T^s)$. If X is a tangent vector field on M^{2n} , let X^H denote its horizontal lift with respect to γ . The Kaehlerian structure (J, g) of M^{2n} is expressed by:

$$J X = \tilde{\pi}_* \underline{f} X^H \tag{2.6}$$

$$\tilde{g}(X, Y) = \mathcal{G}(X^H, Y^H). \tag{2.7}$$

Let \mathcal{L} be the smooth $2n$ -distribution on M^{2n+s} defined by the Pfaffian equations $\eta'_a = 0, 1 \leq a \leq s$. Then \mathcal{L} is precisely the horizontal distribution of γ . Since $\eta'_a \circ \underline{f} = 0$, the f -structure preserves the horizontal distribution.

Therefore (2.6) may be also written $(J X)^H = \underline{f} X^H$. Let $\bar{\nabla}$ be the Riemannian connection of (M^{2n}, \tilde{g}) . By ([21], p.179) one has:

$$\underline{D}_{X^H} Y^H = (\nabla_X Y)^H + \frac{1}{2} \alpha^a \mathcal{G}(\underline{f} X^H, Y^H) \xi'_a. \tag{2.8}$$

REMARK

Let $\pi : N \rightarrow M$ be a Riemannian submersion, cf. B.O'NEILL, [23]. Then $\text{Ker}(\pi_*)$ is the *vertical distribution*, while its complement (with respect to the Riemannian metric of N) is the *horizontal distribution* of the Riemannian submersion. As to our $\tilde{\pi}: M^{2n+s} \rightarrow M^{2n}$ a number of important coincidences occur. Firstly, if M^{2n} is assigned the Riemannian metric (2.7), then $M^{2n+s} \rightarrow M^{2n}$ is a Riemannian submersion. Moreover $\tilde{\pi} = \text{Ker}(\tilde{\pi}_*)$ and therefore the horizontal distribution of the Riemannian submersion is precisely \mathcal{L} .

Let N be an $(m+s)$ -dimensional submanifold of M^{2n+s} , and M an m -dimensional submanifold of M^{2n} , such that there exists a fibering $\pi : N \rightarrow M$ such that $\tilde{\pi} \circ j = i \circ \pi$ and j is a diffeomorphism on fibres. Both $i : M \rightarrow M^{2n}, j : N \rightarrow M^{2n+s}$ stand for canonical inclusions. Let $g = i^* \tilde{g}, G = j^* \mathcal{G}$ be the induced metrics on M and N , respectively. Also we denote by ∇, D the corresponding Riemannian connections of (M, g) and (N, G) , respectively. Let B (resp. h) be the second fundamental form of i (resp. j) and denote by A (resp. W) the Weingarten forms. Let $T(M)^\perp \rightarrow M$ (resp. $T(N)^\perp \rightarrow N$) be the normal bundle of i (resp. j). We put $\xi'_a = \tan(\xi'_a), \xi'^\perp_a = \text{nor}(\xi'_a)$, where \tan_x, nor_x stand for the projections associated with the direct sum decomposition $T_x(M^{2n+s}) = T_x(N) \oplus T_x(N)^\perp, x \in N$. Then the Gauss and Weingarten formulae, (cf. e.g. [24], p.39-40), of i, j and our (2.8) lead to:

$$D_{X^H} Y^H = (\nabla_X Y)^H + \frac{1}{2} \alpha^a \mathcal{G}(\underline{f} X^H, Y^H) \xi'_a \tag{2.9}$$

$$h(X^H, Y^H) = B(X, Y)^H + \frac{1}{2} \alpha^a \mathcal{G}(\underline{f} X^H, Y^H) \xi'_a \tag{2.10}$$

$$W_{V^H} Y^H = (A_{\nabla_X} Y)^H - \frac{1}{2} \alpha^a \mathcal{G}(\underline{f} X^H, V^H) \xi'_a \tag{2.11}$$

$$D^\perp_{X^H} V^H = (\nabla^\perp_X V)^H + \frac{1}{2} \alpha^a \mathcal{G}(\underline{f} X^H, V^H) \xi'^\perp_a \tag{2.12}$$

for any tangent vector fields X, Y on M , respectively any cross-section V in $T(M)^\perp \rightarrow M$. Here ∇^\perp, D^\perp stand for the normal connections of i, j . Of course, towards obtaining our (2.9) - (2.12) one exploits the fact that $(i_* X)^H$ is tangent to N , while V^H is a cross-section in $T(N)^\perp \rightarrow N$.

REMARKS

1) Let $H(i) = \frac{1}{m} \text{Trace} (B)$ (resp. $H(j) = \frac{1}{m+s} \text{Trace}(h)$) be the mean curvature vector of i (resp. j). As an application of our (2.9) - (2.12) one may derive:

$$(m+s) H(j) = m H(i)^H + \sum_{a=1}^s [\frac{1}{2} \alpha_a \text{nor}(f \xi_a^\perp) - D_{\xi_a}^\perp \xi_a^\perp] \tag{2.13}$$

provided that $\{\xi_a: 1 \leq a \leq s\}$ consists of mutually orthogonal unit vector fields. In particular, if N is tangent to each structure vector ξ_a' , $1 \leq a \leq s$, then N is minimal if and only if M is minimal. Indeed, if X is tangent to N , then (2.4) and the Gauss - Weingarten formulae lead to:

$$D_X \xi_a = W_{\xi_a}^\perp X - \frac{1}{2} \alpha_a \text{tan}(f X) \tag{2.14}$$

$$h(X, \xi_a) + D_X^\perp \xi_a^\perp = - \frac{1}{2} \alpha_a \text{nor}(f X). \tag{2.15}$$

Now, if $\{\xi_a: 1 \leq a \leq s\}$ are orthonormal, one uses a frame $\{X_i, \xi_a^H\}$ (where $\{X_i: 1 \leq i \leq m\}$ is an orthonormal tangential frame of M) such as to compute $H(j)$.

2) Generally, if N is a submanifold of the \mathcal{R} -manifold M^{2n+s} and N is normal to some ξ_a' with $\alpha_a = 0$ then tangent spaces at points of N are f -anti-invariant, i.e. $f_x(T_x(N)) \subseteq T_x(N)^\perp$, $x \in N$. Indeed, by (2.4) and the Weingarten formula of N in M^{2n+s} , one has $\mathcal{G}(\alpha_a f X, Y) = -2 \mathcal{G}(D_X \xi_a', Y) = 2 \mathcal{G}(W_{\xi_a}^\perp X, Y)$ where from $W_{\xi_a}^\perp = 0$ and $f X$ is normal to N .

3. \mathcal{R} -MANIFOLDS AS HERMITIAN OR NORMAL ALMOST CONTACT

METRICAL MANIFOLDS.

We denote by $\mathbb{C}P^n$ the complex projective space with constant holomorphic sectional curvature 1 (with Fubini - Study metric) and complex dimension n , and by S^{2n+1} the $(2n+1)$ -dimensional unit sphere carrying the standard Sasakian structure. Let $\pi^1: S^{2n+1} \rightarrow \mathbb{C}P^n$ be the Hopf fibration and set $H^{2n+s} = \{(p_1, \dots, p_s) \in S^{2n+1} \times \dots \times S^{2n+1} \mid \pi^1(p_1) = \dots = \pi^1(p_s)\}$. We define a principal toroidal bundle by the commutative diagram:

$$\begin{array}{ccc} H^{2n+s} & \xrightarrow{\hat{\Delta}} & S^{2n+1} \times \dots \times S^{2n+1} \\ \bar{\pi} \downarrow & & \downarrow \pi^1 \times \dots \times \pi^1 \\ \mathbb{C}P^n & \xrightarrow{\Delta} & \mathbb{C}P^n \times \dots \times \mathbb{C}P^n \end{array}$$

where Δ denotes the diagonal map, while $\hat{\Delta}$ stands for the canonical inclusion. Let η' be the standard contact 1-form on S^{2n+1} . We put $\eta_a' = \hat{\Delta}^* \Delta_a^* \eta'$, $1 \leq a \leq s$ where $\Delta_a: S^{2n+1} \times \dots \times S^{2n+1} \rightarrow S^{2n+1}$ are natural projections. Let Ω be the Kaehler 2-form of $\mathbb{C}P^n$. Then on one hand $\gamma = (\eta_1', \dots, \eta_s')$ is a connection 1-form in $H^{2n+s}(\mathbb{C}P^n, \bar{\pi}, T^s)$, and on the other $d\eta_a' = \bar{\pi}^* \Omega$, such that one may apply theorem 3.1 of [8], (p.163) such as to yield a natural \mathcal{R} -structure on H^{2n+s} . (Cf also [4], p.173). Let $(f, \xi_a, \eta_a, \mathcal{G})$ be the canonical \mathcal{R} -structure

of H^{2n+s} : If s is even one sets:

$$\mathcal{J} = \underline{f} + \sum_{i=1}^s \{ \eta_i \otimes \xi_{i\cdot} - \eta_{i\cdot} \otimes \xi_i \} \tag{3.1}$$

where $i\cdot = i + \frac{s}{2}$, $1 \leq i \leq \frac{s}{2}$. If s is odd, one labels the 1-forms η_a as follows: $\eta_0, \eta_i, \eta_{i\cdot}$, $i\cdot = i+r$, $1 \leq i \leq r$, $s = 2r+1$, and similarly for the tangent vector fields ξ_a . We consider:

$$\varphi = \underline{f} + \sum_{i=1}^r \{ \eta_i \otimes \xi_{i\cdot} - \eta_{i\cdot} \otimes \xi_i \}. \tag{3.2}$$

The characteristic 1-form of H^{2n+s} , s even, is defined by:

$$\omega = 2 \sum_{i=1}^{s/2} \{ \eta_i - \eta_{i\cdot} \}. \tag{3.3}$$

Let $B = \omega^\dagger$ be the characteristic field, where \dagger means raising of indices by \mathcal{G} .

REMARKS

1) If s is even then $(H^{2n+s}, \mathcal{J}, \mathcal{G})$ is a Hermitian non-Kaehlerian manifold and its characteristic form is parallel. Indeed, if s is even, then \mathcal{J} given by (3.1) is a complex structure and $(H^{2n+s}, \mathcal{J}, \mathcal{G})$ turns to be a Hermitian manifold, (cf. prop.4.1 in [8], p.174). Let $\tilde{F}(X, Y) = \mathcal{G}(X, \mathcal{J} Y)$ be its Kaehler 2-form. By (3.1) it follows that $\tilde{F} = F - 2 \sum_{i=1}^{s/2} \eta_i \wedge \eta_{i\cdot}$; consequently (3.3) leads to

$$dF = \omega \wedge F \tag{3.4}$$

i.e. \mathcal{G} is not a Kaehler metric. Now our (2.4) yields $\underline{D} \omega = \frac{1}{2} \sum_{i=1}^{s/2} (\alpha_i - \bar{\alpha}_{i\cdot}) F$ on an arbitrary \mathcal{R} -manifold, provided s is even. Yet for H^{2n+s} one has $\alpha_1 - \dots - \alpha_s$, (cf.[8],p.173), i.e. ω is parallel.

2) Since $d\eta^a = \tilde{\pi}^a \Omega$, $1 \leq a \leq s$, it follows that ω is closed. Therefore H^{2n+s} , s even, admits the canonical foliation \mathcal{F} defined by the Pfaffian equation $\omega = 0$. Each leaf of \mathcal{F} is a totally-geodesic real hypersurface normal to the characteristic field of H^{2n+s} .

3) Consider the submanifolds $i : M \rightarrow \mathbb{C}P^n$ and $j : N \rightarrow H^{2n+s}$ and assume that a T^s -subbundle $\pi : N \rightarrow M$ of the generalized Hopf fibration, i.e. $\tilde{\pi} \circ j = i \circ \pi$ and j is a diffeomorphism on fibres. Suppose N is tangent to the structure vectors ξ_a of the \mathcal{R} -manifold H^{2n+s} . Then M is a C.R. submanifold of $\mathbb{C}P^n$ if and only if N is either a C.R. submanifold of $(H^{2n+s}, \mathcal{J}, \mathcal{G})$ or a contact C.R. submanifold of $(H^{2n+s}, \varphi, \xi_0, \eta_0, \mathcal{G})$. Note firstly that, if s is odd, then $(\varphi, \xi_0, \eta_0, \mathcal{G})$ is a normal almost contact metrical (a. ct. m.) structure on H^{2n+s} , (cf. [8], p.175). If $\xi_a^\perp = 0$, $1 \leq a \leq s$, and s is even then:

$$\mathcal{J} \xi_i = \xi_{i\cdot}, \quad \mathcal{J} \xi_{i\cdot} = -\xi_i, \quad \mathcal{J} X^H = (J X)^H \tag{3.5}$$

for any tangent vector field X on M , cf.(2.6). Let us define $\mathcal{P} Y = \tan(\mathcal{J} Y)$, $\mathcal{P}^\perp Y = \text{nor}(\mathcal{J} Y)$, for any tangent vector field Y on N . Then:

$$\mathcal{P}^\perp \mathcal{P} \xi_i = 0, \quad \mathcal{P}^\perp \mathcal{P} \xi_{i\cdot} = 0, \quad \mathcal{P}^\perp \mathcal{P} X^H = (F P X)^H \tag{3.6}$$

where F, P are defined by (1.1) in [7] (p.76). Suppose for instance that $(M, \mathcal{D}, \mathcal{D}^\perp)$ is a C.R. submanifold of $\mathbb{C}P^n$. Then P is \mathcal{D} -valued, while F vanishes on

\mathcal{D} , i.e. $FP = 0$. By (3.6) one has $\mathcal{D}^\perp \mathcal{D} = 0$, and thus one may apply theor. 3.1 in [7] (p.87), such as to conclude that N is a C.R. submanifold of $(H^{2n+1}, \mathcal{G}, \mathcal{D})$. Note that, although stated for submanifolds in Kaehlerian manifolds, theor.3.1 of [7] (p.87) actually holds for the general case of an arbitrary almost Hermitian ambient space. The case s odd follows similarly from theor. 2.1 of [7] (p.55) which may be easily refined from the Sasakian case to the general case of a. ct. m. structures.

4) Let $(M, \mathcal{D}, \mathcal{D}^\perp)$ be a C.R. submanifold of CP^n , where \mathcal{D} (resp. \mathcal{D}^\perp) denotes the holomorphic (resp. totally-real) distribution. Let $\pi : N \rightarrow M$ be a T^s -bundle as in Remark 3). Let $\mathcal{D}_N, \mathcal{D}_N^\perp$ be the holomorphic and totally-real (resp. the ϕ -invariant and ϕ -anti-invariant) distributions of N , provided that s is even (resp. s is odd). Let $\ell_{N,x}$ the natural projection on the first term of the direct sum decomposition $T_x(N) = \mathcal{D}_{N,x} \oplus \mathcal{D}_{N,x}^\perp, x \in N$. Cf. (3.7) in [7] (p.86), (resp. cf. (2.10) in [7] (p.53)) if s is even (resp. if s is odd) then ℓ_N is expressed by $\ell_N = -\mathcal{D}^2$ (resp. by $\ell_N = -\mathcal{D}^2 + \eta_0 \otimes \xi_0$) where $\mathcal{D}Y = \tan(\mathcal{G}Y)$, (resp. $\mathcal{D}Y = \tan(\phi Y)$). In both cases one has:

$$\ell_N \xi_a = \xi_a, \quad 1 \leq a \leq s, \quad \ell_N X^H = (\ell X)^H \tag{3.7}$$

where $\ell = -P^2$. As the sum $\mathcal{D}_x^H + \mathcal{D}_x^\perp, x \in N$, is direct one obtains $\mathcal{D}_{N,x}^H = \mathcal{D}_x^H \oplus \mathcal{D}_x^\perp, x \in N$. Indeed, one inclusion follows from (3.7). Conversely, let $X' \in \mathcal{D}_N^H$, then $X' = (\ell X)^H + (\ell^\perp X)^H + \lambda^a \xi_a, \lambda^a \in C^\infty(N), \ell^\perp = I - \ell$. By applying ℓ_N to both members one proves $X' \in \mathcal{D}^H \oplus \mathcal{D}^\perp$. It is also straightforward that $(\mathcal{D}^\perp)^H = \mathcal{D}_N^\perp$.

4.- FRAMED CAUCHY-RIEMANN SUBMANIFOLDS

S. GOLDBERG, [25], has inaugurated a program of unifying the treatment of the cases s even, and s odd, and studied f -invariant submanifolds of codimension 2 of an \mathcal{R} -manifold. To make the terminology precise, let $(N, \mathcal{D}, \mathcal{D}^\perp)$ be a framed C.R. submanifold of M^{2n+1} ; we call N an f -invariant (resp. f -anti-invariant) submanifold if $\mathcal{D}_x^\perp = (0)$, (resp. if $\mathcal{D}_x = (0)$), for any $x \in N$.

Let M^{2n+1} be an \mathcal{R} -manifold; let $x \in M^{2n+1}$ and $p \subseteq T_x(M^{2n+1})$ a 2-plane. (Cf.[8], p.159), p is an f -section if it is spanned by $\{X, f X_x\}$ for some unit tangent vector $X \in \mathcal{D}_x$. The Riemannian sectional curvature of (M^{2n+1}, \mathcal{D}) restricted to f -sections is referred to as the f -sectional curvature of the \mathcal{R} -manifold. (Cf. also [21], p.183).

At this point we may establish i) of theor. A. Let X, V be respectively a tangent vector field on N and a cross-section in $T(N)^\perp \rightarrow N$. We set $PX = \tan(f X), FX = \text{nor}(f V)$ and $fV = \text{nor}(f V)$. The following identities hold as direct consequences of definitions:

$$\begin{aligned} P^2 + tF &= -I + \eta_a \otimes \xi^a, & FP + fF &= 0, & Pt + tf &= 0, \\ Ft + f^2 &= -I, & f\ell &= P\ell, & F\ell &= 0, \\ f\ell^\perp &= F\ell^\perp, & P\ell^\perp &= 0. \end{aligned} \tag{4.1}$$

Using (2.5) and the Gauss - Weingarten formulae of N in M^{2n+1} one obtains:

$$\begin{aligned} (D_X P)Y &= W_{FY}X + t h(X, Y) + \\ &+ \frac{1}{2}\alpha^a \{[G(X, Y) - \eta_b(X) \eta^b(Y)] \xi_a - [X - \eta_b(X) \xi^b] \eta_a(Y)\} \end{aligned} \tag{4.2}$$

for any tangent vector fields X, Y on N . Let $X, Y \in \mathcal{D}^\perp$. As D is torsion-free

and by (4.2) one obtains:

$$P[X, Y] = W_{FX} Y - W_{FY} X + \alpha^a \left\{ \frac{1}{2} (X \wedge Y) \xi_a + (\eta_a \wedge \eta_b) (X, Y) \xi^b \right\} \quad (4.3)$$

At this point we may establish the following:

LEMMA

Let $(N, \mathcal{D}, \mathcal{D}^\perp)$ be a framed C.R. submanifold of the \mathcal{S} -manifold M^{2n+s} . Then:

$$W_{FX} Y = W_{FY} X + \frac{1}{2} \alpha^a \{ \eta_a(X) Y - \eta_a(Y) X - [\eta_a(X) \eta_a(Y) - \eta_a(Y) \eta_a(X)] \xi^b \} \quad (4.4)$$

for any $X, Y \in \mathcal{D}^\perp$.

Proof. By (4.1), P vanishes on \mathcal{D}^\perp . Using (4.2), for any $X, Y \in \mathcal{D}^\perp, Z \in T(N)$, one has:

$$0 = G((D_Z P)X, Y) = G(W_{FX} Z, Y) + G(t h(Z, X), Y) + \frac{1}{2} \alpha^a \{ G(Z, X) \eta_a(Y) - G(Z, Y) \eta_a(X) + [\eta_a(X) \eta^b(Y) - \eta_a(Y) \eta^b(X)] \eta_b(Z) \}$$

and finally $G(t h(Z, X), Y) = -G(W_{FY} X, Z)$ leads to (4.4).

By (4.3) and the above lemma we conclude $P[X, Y] = 0$, i.e. \mathcal{D}^\perp is involutive.

Let us prove now ii) in theor. A. We analyse for instance the case s even. Let N a framed C.R. submanifold of H^{2n+s} . Let

$$\mathcal{F} = P + \sum_{i=1}^{s/2} \eta_i \otimes \xi_{i^*} - \eta_{i^*} \otimes \xi_i, \quad \mathcal{F}^\perp = F \quad (4.5)$$

Next $\mathcal{F}^\perp \mathcal{F} = F P = 0$, and one applies theor.3.1 of [7], p.87. The case s odd being similar is left as an exercise to the reader. To prove the converse of ii) in theor.A we need to characterize framed C.R. submanifolds as follows. Let N be a framed C.R. submanifold of an \mathcal{S} -manifold M^{2n+s} . Then (4.1) leads to $P \mathcal{L} = P, F P = 0, f F = 0$, etc. One obtains the following statement. *Let N be a submanifold of the \mathcal{S} -manifold M^{2n+s} such that N is tangent to the structure vectors ξ_a . Then N is a framed C.R. submanifold of M^{2n+s} if and only if $F P = 0$. We have proved the necessity already. Viceversa, let us put by definition $\mathcal{L} = -P^2 + \eta_a \otimes \xi^a, \mathcal{L}^\perp = I - \mathcal{L}$. Since $F P = 0$, the projections $\mathcal{L}, \mathcal{L}^\perp$ make N into a framed C.R. submanifold, Q.E.D. Now the converse of ii) in theor. A is easily seen to hold, i.e. both C.R. submanifolds of $(H^{2n+s}, \mathcal{L}, \mathcal{G})$, s even, and contact C.R. submanifolds of $(H^{2n+s}, \varphi, \xi_0, \eta_0, \mathcal{G})$, s odd, are framed C.R. submanifolds.*

REMARKS

1) Let $(N, \mathcal{D}, \mathcal{D}^\perp)$ be a framed C.R. submanifold of H^{2n+s} . By (4.5) one obtains:

$$\mathcal{F}^2 = P^2 - \eta^a \otimes \xi^a. \quad (4.6)$$

Now the notion of framed C.R. submanifold appears to be essentially on old concept. For not only N becomes a C.R. submanifold of the Hermitian manifold H^{2n+s} , if for instance s is even, but its holomorphic and totally-real distributions are precisely $\mathcal{D}, \mathcal{D}^\perp$. Indeed, by (4.6) one has $\mathcal{L}_N = \mathcal{L}$, Q.E.D.

2) Due to (3.4) there is a certain similarity between \mathcal{S} -manifolds and locally conformal Kaehler manifolds, cf. P.LIBERMANN, [26]. See also [12]. For instance, we may use the ideas in [2] (cf. also theor. 3.4 of [7], p.89) to

give an other proof of the integrability of the f -anti-invariant distribution of a framed C.R. submanifold. Indeed, let N be a framed C.R. submanifold of H^{2n+s} , s even. Let $X \in \mathcal{D}$, $Z, W \in \mathcal{D}^\perp$. By (3.4) one has $0 = 3(d\tilde{F})(X, Y, W) = -G([Z, W], JX)$. Hence $[Z, W] \in \mathcal{D}^\perp$. Note that, although N is C.R. in the usual sense one could not apply theor.3.4 or theor.4.1 of [7] (p.89-90) since H^{2n+s} is neither locally conformal Kaehler nor Kaehler.

To establish iii) let N be an f -invariant submanifold of H^{2n+s} . As a consequence of (2.5), for any tangent vector fields X, Y on N one has:

$$(D_X \mathfrak{f}) Y = \frac{1}{2} \alpha^s \{ [G(X, Y) - \eta_b(X) \eta^b(Y)] \xi_a - [X - \eta_b(X) \xi^b] \eta_a(Y) \} \tag{4.7}$$

$$h(X, \mathfrak{f} Y) = \mathfrak{f} h(X, Y). \tag{4.8}$$

Let $k(X, Y)$ be the Riemannian sectional curvature of the 2-plane spanned by the orthonormal pair $\{X, Y\}$ on N ; using the Gauss equation, i.e. equation (2.6) in [24], (p.45), and the notations in [4], (p.161), i.e. $H(X) = k(X, fX)$, $X \in \mathcal{D}$, one obtains:

$$1 - \frac{3}{4} s = H(X) + 2 \| h(X, X) \|^2 \tag{4.9}$$

as H^{2n+s} has constant f -sectional curvature, (cf.[8], p.173). By (2.15) and f -invariance one has $h(X, \xi_a) = -\frac{1}{2} \alpha_a$ nor $(\mathfrak{f} X) = 0$; a standard argument based on (4.8) leads to the proof.

To prove iv) one uses $D h = 0$, (2.15) and f -invariance, i.e. one has $h((D_X \xi_a), Y) = 0$. Thus $\alpha_a h(\mathfrak{f} X, Y) = 0$, by (2.14). For some $\alpha_a = 0$ one uses (4.7). Finally, apply once more \mathfrak{f} and notice that η'_a vanish on normal vectors. Thus $h = 0$.

REMARK

Let \mathcal{F} be the canonical foliation of H^{2n+s} . Let N be a framed C.R. submanifold of H^{2n+s} , as above. Then $\mathcal{D}^\perp \subseteq \mathcal{F}$, i.e. the totally-real foliation of N (regarded as a C.R. submanifold, s even) is normal to the characteristic field $2 \sum_{i=1}^{s/2} (\xi_i - \xi_{i+s})$ of H^{2n+s} . Indeed, since $\xi_a \in \mathcal{D}^\perp$, the η_a vanish on \mathcal{D}^\perp . Thus $\omega \circ \mathcal{L}^\perp = 0$.

5.- THE CHEN CLASS OF A CAUCHY-RIEMANN SUBMANIFOLD.

Let M be a C.R. submanifold of CP^n . Let $\pi : N \rightarrow M$ be a T^s -fibration, as in theor. B. Assume s is even. Then N is a C.R.submanifold of H^{2n+s} and its totally-real distribution is integrable. We shall need the following:

LEMMA

The holomorphic distribution of N is minimal.

Proof.

Note that we may not use lemma 4. in [17] (p.169) since its proof makes essential use of the Kaehler property. Neither could one use corollary 2.3 of [27] (p.291), (although $\mathcal{D}^\perp_N \subseteq \mathcal{F}$) since $(\mathcal{L}, \mathcal{D})$ fails to be locally conformal Kaehler. Now (2.4) - (2.5), (3.1) lead to:

$$(D_X \mathcal{D}) Y = \frac{1}{2} \{ [\mathcal{D}(X, Y) - \eta_b(X) \eta^b(Y)] \xi - [X - \eta_b(X) \xi^b] \eta(Y) \} - \frac{1}{4} \{ \mathfrak{F}(X, Y) B + \omega(Y) \mathfrak{f} X \} \tag{5.1}$$

where $\eta = \sum_{a=1}^s \eta_a$, $\xi = \eta^\dagger$. Let $X \in \mathcal{D}_N$, $Z \in \mathcal{D}_N^\perp$. Using (5.1) we have:

$$(Z, \mathcal{D}_X X) = \mathcal{G}(\mathcal{L} Z, \mathcal{L} \mathcal{D}_X X) = \mathcal{G}(\mathcal{L} Z, \mathcal{D}_X \mathcal{L} X) = \mathcal{G}(\mathcal{L} X, \mathcal{L} X).$$

Thus: $\mathcal{G}(Z, \mathcal{D}_X X + \mathcal{D}_{\mathcal{L} X} \mathcal{L} X) = 0$ and \mathcal{D}_N^\perp follows to be minimal. Let $p = \dim_{\mathbb{C}} \mathcal{D}$. Let $\{X_A : 1 \leq A \leq 2p\}$ be a real orthonormal frame of \mathcal{D} , where $X_{i+p} = \mathcal{L} X_i$, $1 \leq i \leq p$. Then $\{X_A^H, \xi_a\}$ is an orthonormal frame of \mathcal{D}_N . Let λ^A , $1 \leq A \leq 2p$, be differential 1-forms on N defined by $\lambda^A(X_B) = \delta_B^A$, $\lambda^A(Y) = 0$, for any $Y \in \mathcal{D}_N^\perp$. Let $\lambda = \lambda^1 \wedge \dots \wedge \lambda^{2p} \wedge \eta^1 \wedge \dots \wedge \eta^s$. Then λ is a globally defined $(2p+s)$ -form on N , as \mathcal{D}_N is orientable. We leave it as an exercise to the reader to follow the ideas in [17] (p.170) and show that since \mathcal{D}_N is minimal and \mathcal{D}_N^\perp integrable the $(2p+s)$ -form λ is closed. Thus λ determines a cohomology class $c(N) = [\lambda] \in H^{2p+s}(N; \mathbb{R})$ referred to as the *Chen class* of N .

To prove theor. B suppose M is a C.R. product, i.e. M is locally a product of a complex submanifold and a totally-real submanifold of $\mathbb{C}P^n$, see e.g. [28], (p.63). Now C.R. products have an integrable holomorphic distribution and a minimal totally-real distribution. By (2.8), for any tangent vector fields X, Y on $\mathbb{C}P^n$ one has:

$$[X^H, Y^H] = [X, Y]^H - \alpha^a F(X^H, Y^H) \xi_a. \tag{5.2}$$

Then (5.2) used for $X = X_A$, $Y = X_B$ leads to $[X_A^H, X_B^H] \in \mathcal{D}_N$. Next, as $\mathcal{D}_N^\perp X_A^H = 0$ one has

$$\mathcal{D}_N^\perp [X_A^H, \xi_a] = (\mathcal{D}_{\xi_a} \mathcal{D}_N^\perp) X_A^H - \mathcal{D}_N^\perp \mathcal{D}_X X_A^H \xi_a. \tag{5.3}$$

We need the following :

LEMMA

The covariant derivative $(\mathcal{D}_X \mathcal{D}_N^\perp) Y = \mathcal{D}_X^\perp \mathcal{D}_N^\perp Y - \mathcal{D}_N^\perp \mathcal{D}_X Y$ of \mathcal{D}_N^\perp is expressed by:

$$(\mathcal{D}_X \mathcal{D}_N^\perp) Y = -h(X, \mathcal{D}_N^\perp Y) + f h(X, Y) - \frac{1}{4} \omega(Y) F X \tag{5.4}$$

for any tangent vector fields X, Y on N . Here $f V = \text{nor}(\mathcal{L} V)$ for any cross-section V in $T(N) \rightarrow N$.

Proof.

Let also $t V = \tan(\mathcal{L} V)$. Using the Gauss and Weingarten formulae of N in H^{2n+1} one has:

$$\begin{aligned} (\mathcal{D}_X \mathcal{L}) Y &= (\mathcal{D}_X \mathcal{D}_N^\perp) Y - W \mathcal{D}_N^\perp Y X - th(X, Y) + \\ &+ (\mathcal{D}_X \mathcal{D}_N^\perp) Y + h(X, \mathcal{D}_N^\perp Y) - f h(X, Y) \end{aligned} \tag{5.5}$$

Let us use (5.1) to substitute in (5.5); a comparison between the normal components in (5.5) leads to (5.4), Q.E.D.

Now we may use the above lemma to end the proof of the involutivity of \mathcal{D}_N . Indeed, by (5.4) and (2.4) our (5.3) turns into:

$$\mathcal{D}_N^\perp [X_A^H, \xi_a] = -h(\xi_a, \mathcal{D}_N^\perp X_A^H) + f h(\xi_a, X_A^H) - \frac{1}{4} \omega(X_A^H) F \xi_a + \frac{1}{2} \alpha^a \mathcal{D}_N^\perp \xi_a X_A \tag{5.6}$$

and by (2.15) one obtains $\mathcal{D}_N^\perp [X_A^H, \xi_a] = 0$.

The last step is to establish minimality of \mathcal{D}_N^\perp . Let $q = \dim_{\mathbb{R}} \mathcal{D}_x^\perp$, $x \in M$.

If $\{E_i: 1 \leq i \leq q\}$ is an orthonormal frame of \mathcal{D}^\perp then (2.8) yields:

$$\int_N \sum_{i=1}^q \underline{D} E_i^H E_i^H = \left\{ \int_N \sum_{i=1}^q \bar{\nabla} E_i^H E_i^H \right\}. \quad (5.7)$$

But \mathcal{D}^\perp is minimal, so the right hand member of (5.7) is zero. Finally, one may follow the ideas in [17], (p.170) to show that since \mathcal{D}_N is integrable and \mathcal{D}_N^\perp minimal the $(2p+s)$ -form λ is coclosed. As N is compact, λ is harmonic. Thus $c(N) = [\lambda] \neq 0$, and our theor. B is completely proved.
