On the Burau representation modulo a small prime

D COOPER
 D D LONG

Abstract We discuss techniques for analysing the structure of the group obtained by reducing the image of the Burau representation of the braid group modulo a prime. The main tools are a certain sesquilinear form first introduced by Squier and consideration of the action of the group on a Euclidean building.

AMS Classification 20F36; 57M07 57M25

Keywords Burau representation, braid group, Euclidean building, Squier form

1 Introduction

Despite the work of many authors, the group theoretic image of linear representations of the braid groups remains mysterious in most cases. The first nontrivial example, the *Burau representation* is not at all well understood. This representation

$$\beta_n: B_n \rightarrow GL(n-1, \mathbf{Z}[t, t^{-1}])$$

is known not to be faithful for $n \geq 6$ ([5] and [6]) but the nature of the image group and in particular, a presentation for the image group has not been found. In [3], we simplified the problem by composing β_n with the map which reduces coefficients modulo 2. In this way, we were able to give a presentation for the image of the simplified representation $\beta_4 \otimes \mathbf{Z}_2$. (Throughout this paper we use the notation \mathbf{Z}_p for the finite field with p elements.) Of course, the motivation for this approach comes from the classical problem of whether the representation β_4 is faithful and to this end we pose the question:

Question 1.1 Is there any prime p for which the representation

$$\beta_4 \otimes \mathbf{Z}_p: B_4 \rightarrow GL(3, \mathbf{Z}_p[t, t^{-1}])$$

is faithful?

It is a consequence of some results of this note that the representation is not faithful in the case $p = 3$, (below we exhibit a braid word in the kernel) however the program for attacking the problem runs into difficulty at the final stage when $p = 5$. This case remains open and has some features which suggest it may be different to the first two primes.

In order to describe our approach, we recall that the group $GL(3, \mathbf{Z}_p[t, t^{-1}])$ acts on a certain contractible two dimensional simplicial complex, $\Delta = \Delta(p)$ a so-called *Euclidean building* (see [2]). This is defined by embedding

$$GL(3, \mathbf{Z}_p[t, t^{-1}]) \longrightarrow GL(3, \mathbf{Z}_p(t))$$

where $\mathbf{Z}_p(t)$ is the field of fractions of the ring $\mathbf{Z}_p[t, t^{-1}]$. This target group admits a discrete rank one valuation defined by $\nu(p/q) = \text{degree}(q) - \text{degree}(p)$. A standard construction now yields the complex Δ . We briefly outline how this building and action are defined, restricting our attention to the case $n = 4$, since this is the only case in which we shall subsequently be interested. This will serve the additional purpose of establishing notation. Standard properties of ν imply that

$$\mathcal{O} = \{x \in \mathbf{Z}_p(t) \mid \nu(x) \geq 0\}$$

is a subring of $\mathbf{Z}_p(t)$, the *valuation ring* associated to ν . This is a local ring and the unique maximal ideal is easily seen to be $\mathcal{M} = \{x \in \mathbf{Z}_p(t) \mid \nu(x) > 0\}$, a principal ideal. Choose some generator π for this ideal. This element is called a *uniformizing parameter* and by construction we have that $\nu(\pi) = 1$. Since \mathcal{M} is maximal, the quotient $k = \mathbf{Z}_p(t)/\mathcal{M}$ is a field, the *residue class field*. One sees easily that in this case, the residue class field is \mathbf{Z}_p .

Now let V be the vector space $\mathbf{Z}_p(t)^3$. By a *lattice* in V we shall mean an \mathcal{O} -submodule, L , of the form $L = \mathcal{O}x_1 \oplus \mathcal{O}x_2 \oplus \mathcal{O}x_3$ where $\{x_1, x_2, x_3\}$ is some basis for V . Thus the columns of a non-singular 3×3 matrix with entries in $\mathbf{Z}_p(t)$ defines a lattice. The standard lattice is the one corresponding to the identity matrix. We define two lattices L and L' to be equivalent, if for some $\lambda \in \mathbf{Z}_p(t)^*$ we have $L = \lambda L'$. We denote equivalence class by $[L]$. The building Δ is defined as a flag complex in the following way. The points are equivalence classes of lattices, and $[L_0], \dots, [L_k]$ span a k -simplex (in our situation $k = 0, 1, 2$ are the only possibilities) if and only if one can find representatives so that $\pi L_0 \subset L_1 \subset \dots \subset L_k \subset L_0$.

All 2-simplices are of the form $\{[x_1, x_2, x_3], [x_1, x_2, \pi x_3], [x_1, \pi x_2, \pi x_3]\}$; this is usually referred to as a *chamber* and denoted by C . Clearly the group $GL_3(\mathbf{Z}_p(t))$ acts on lattices and one sees easily that incidence is preserved, so that the group acts simplicially on Δ . It is shown in [2] that this building

is a so-called *Euclidean building*, in particular, it is contractible and can be equipped with a metric which makes it into a $CAT(0)$ space and for which $GL_3(\mathbf{Z}_p(t))$ acts as a group of isometries. The metric is such that each 2 dimensional simplex is isometric to a unit Euclidean equilateral triangle.

We now return to our situation. One of the difficulties of dealing with representations of braid groups is that it is extremely difficult to determine exactly which matrices are in the image. We bypass this by dealing with a group which contains $im(\beta_4 \otimes \mathbf{Z}_p)$. To define this group, we recall that it was shown by Squier [7] that the Burau representation is unitary in the sense that there is a matrix

$$J = \begin{pmatrix} -(s + 1/s) & 1/s & 0 \\ s & -(s + 1/s) & 1/s \\ 0 & s & -(s + 1/s) \end{pmatrix}$$

with the property that $A^*JA = J$ for all $A \in im(\beta_n)$. Here the involution $*$ comes from extending the involution of $\mathbf{Z}_p[t, t^{-1}]$ generated by $t \rightarrow 1/t$ to the matrix group by $(a_{i,j})^* = (a_{j,i}^*)$, where $s^2 = t$.

We define the subgroup $Isom_J(\Delta)$ of $GL(3, \mathbf{Z}_p(t))$ to be those matrices with Laurent polynomial entries which are unitary for the form J . The advantage of dealing with this subgroup is that the condition that a matrix lies inside $Isom_J(\Delta)$ is easily used.

The strategy now is to examine the action of $Isom_J(\Delta)$ on Δ . This is interesting in its own right. Moreover, the greater ease of dealing with this subgroup means that we are able to compute the complex $\Delta/Isom_J(\Delta)$ together with all vertex, edge and 2-simplex stabilisers. We then appeal to results of Haefliger [4] to compute a presentation for the group $Isom_J(\Delta)$.

Now recall that homotheties act trivially on Δ so that the presentation for $Isom_J(\Delta)$ is to be compared with the following presentation of $B_4/centre(B_4)$:

Lemma 1.2 *The group $B_4/centre(B_4)$ is presented as*

$$\langle x, y \mid x^4 = y^3 = 1 \quad [x^2, yxy] = 1 \rangle$$

where $x = \sigma_1\sigma_2\sigma_3$ and $y = x\sigma_1$.

This is presumably well known to the experts—it is derived in [3]. The starting point for this work is:

Lemma 1.3 *The group $stab_J(I)$ acts on Δ as a finite group.*

Sketch of proof If $A \in \text{stab}_J(I)$, then its action on Δ is unchanged by homothety and it's easily seen that we can adjust any such A by applying $\pm t^k$ so that $A \in SL(3, \mathcal{O})$. Rewriting the unitary condition as $A^* = JA^{-1}J^{-1}$ and noting that $J \in GL(3, \mathcal{O})$, we see that $A^* \in SL(3, \mathcal{O})$. However the only matrices with Laurent polynomial entries for which A and A^* have all entries valuing positively are the constant matrices.

Thus we have shown that the only such A have constant entries up to homothety. In particular, they are unchanged by setting $t = 1$, so that $\text{stab}_J(I)$ can be regarded as a subgroup of the finite group $GL(3, \mathbf{Z}_p)$, completing the proof. \square

This has the immediate corollary:

Corollary 1.4 *For every vertex $v \in \Delta$, $\text{stab}_J(v)$ is a finite group.*

Proof The building Δ is locally finite, in fact the link of every vertex is the flag manifold in the vector space \mathbf{Z}_p^3 . The stabiliser of any vertex acts on this set as a group of permutations, so by passing to a subgroup of finite index in $\text{stab}_J(v)$ we obtain a subgroup which acts as the identity on all vertices in the link. Since every vertex is connected to I by some chain of vertices, we see that for every v , there is a subgroup of finite index which lies inside $\text{stab}_J(I)$, a finite group. \square

We now focus on the case $p = 3$. In this case one finds by calculation:

Theorem 1.5 *At the prime 3, group $\text{stab}_J(I)$ acts on Δ as $\mathbf{Z}_4 \cong \langle x \rangle$.*

Remark 1.6 For $p = 2, 3, 5$, the group $\text{stab}_J(I)$ acts as the cyclic group \mathbf{Z}_4 . For $p = 7$ it is cyclic of order 8 and for $p = 11$, cyclic of order 12.

One important difference between the case $p = 2$ and that of the larger primes is that it is one of the consequences of the results of [3] that $\text{Isom}_J(\Delta(2)) \cong \text{im}(\beta_4 \otimes \mathbf{Z}_2)$, this is not so for (at least some and conjecturally all) primes $p \geq 3$. In particular, for $p = 3$, we are able to construct (see below) an element $u \in \text{Isom}_J(\Delta(3))$ which has order 6; it is easy to see that this element does not lie in the subgroup $\text{im}(\beta_4 \otimes \mathbf{Z}_3)$. Its matrix is given by:

$$u = \begin{pmatrix} 2+t+t^2 & 2+t^2 & 2+2t+2t^2 \\ 2+2t^2 & 2+t+2t^2 & 2+t+t^2 \\ 2+t & 2+t & 2+2t \end{pmatrix}$$

However, having noted this difference, the qualitative picture of the quotient complex is very similar to the case $p = 2$; the complex consists of a compact piece coming from behaviour of groups close to the identity lattice, together with a single annular end. Application of Haefliger's methods yields the following group theoretic result:

Theorem 1.7 *When $p = 3$, the group $Isom_J(\Delta)$ is presented as:*

Generators: x, y, u

Relations:

- (1) $x^4 = y^3 = u^6 = 1$
- (2) $[x^2, yxy] = 1$
- (3) $[x, u^{-1}x^{-1}y^{-1}xyxy] = 1$
- (4) $[yxy, u^{-1}x^{-1}y^{-1}xyxy] = 1$
- (5) $[xyx, u^2] = 1$
- (6) $[x^2yx, u^3] = 1$
- (7) $(u^2x^2yx)^2 = (x^2yxu^2)^2$
- (8) *Infinitely many other relations to do with nilpotence.*

Of course the verification that these relations hold is a trivial matter of multiplying matrices modulo 3. We remark that the relations contained in (8) are explicitly known.

We claim that a computer application of the Reidemeister–Schreier algorithm contained in the computer program *GAP* applied to the presentation involving the first seven relations proves:

Corollary 1.8 *The index $[Isom_J(\Delta) : \langle x, y \rangle]$ is finite.*

This index is a divisor of 162. The corollary already implies that $im(\beta_4 \otimes \mathbf{Z}_3)$ is not faithful. One way to see this is that one sees easily (for example from the matrix representation) that the element $w = u^{-1}x^{-1}y^{-1}xyxy$ has infinite order. The presentation implies that it commutes with x . However, since $[Isom_J(\Delta) : \langle x, y \rangle]$ is finite, some power of w lies in the subgroup generated by x and y and this gives an unexpected element commuting with x . Alternatively, in the course of the proof, one discovers that $Isom_J(\Delta)$ contains arbitrarily large soluble subgroups and this can also be used to show that the representation is not faithful. In fact, one can be more specific; the computer can be used to

give a presentation for the subgroup generated by $\langle x, y \rangle$; one finds for example, that there is a relation (where $\bar{x} = x^{-1}$ and $\bar{y} = y^{-1}$):

$$\begin{aligned} &\bar{x}.\bar{y}.\bar{x}.y.x.\bar{y}.x.y.x.\bar{y}.x.\bar{y}.\bar{x}.y.x.y.\bar{x}.\bar{y}.\bar{x}.\bar{y}.\bar{x}.y.x.\bar{y}.\bar{x}.\bar{y}.\bar{x}.y.x.\bar{y}.x.y.x.\bar{y}.x.\bar{y}. \\ &\bar{x}.y.x.y.x.\bar{y}.\bar{x}.\bar{y}.x.y.x.\bar{y}.\bar{x}.\bar{y}.\bar{x}.y.x.\bar{y}.x.y.x.\bar{y}.\bar{x}.\bar{y}.y.x.y.x.\bar{y}.\bar{x}.\bar{y}.x.y.x.\bar{y} \end{aligned}$$

That this relation does not hold in the braid group is easily checked by computing the integral Burau matrix.

2 Outline of the proof for $p = 3$

In spirit, if not in detail, the proof follows the ideas introduced in [3], to which we refer the reader. We work outwards from the identity lattice, successively identifying point stabilisers. This enables us to find representatives for each orbit and hence build the quotient complex. The compact part alluded to above comes from the action of the group on vertices fairly close to the orbit of the identity; as one moves farther away there is a certain amount of stabilisation and it is this which gives rise to the single annular end.

We refer to the orbit of the lattice I as the *group points*. The result Lemma 1.3 shows that every group point has stabiliser \mathbf{Z}_4 . We recall the link of any vertex may be considered as the flag geometry of the vector space \mathbf{Z}_3^3 , so that every vertex has 26 points in its link, and each vertex in the link is adjacent to four other vertices in the link.

We need to recall the notation introduced in [3]. We make a (noncanonical) choice of representative lattices for each of the 26 vertices by writing down matrices whose columns define the lattice. Subsequent vertices are coded by using these matrices, regarded as elements of $GL(3, \mathbf{Z}_3[t, t^{-1}])$ as acting on Δ . As an example, denoting the matrix representative chosen for the thirteenth vertex by M_{13} , then the representative elements in the link of the the thirteenth vertex are chosen to be $M_{13}.M_j$ for $1 \leq j \leq 26$. Of course, one vertex has several names in this notation, for example the identity vertex appears in the link of each of its vertices.

The first task is to examine how many group points lie in the link of the identity.

Lemma 2.1 *Link(I) contains precisely 18 group points:*

$$\begin{aligned} &y, \quad y^2, \quad x.y, \quad x.y^2, \quad x^2.y, \quad x^2.y^2, \\ &x^3.y, \quad x^3.y^2, \quad y.x.y, \quad (y.x.y)^{-1}, \quad x.y.x.y, \quad x.(y.x.y)^{-1}, \\ w, \quad w^{-1}, \quad (y.x.y)^{-1}.w, \quad x.(y.x.y)^{-1}.w, \quad y.x.y.w^{-1}, \quad x.y.x.y.w^{-1}, \end{aligned}$$

where w is the element introduced at the end of section 1.

Of course the fact that these are all group points is immediate and the fact that they are distance one from I is a calculation. The content of the lemma is that there are no more group points. This proved by noting that the lattice

$$M_{19} = \begin{pmatrix} 1 & 0 & t \\ 0 & t & 0 \\ 0 & 0 & t \end{pmatrix}$$

is in the link of the identity and is stabilised by the element u . Thus it cannot be a group point as its stabiliser contains an element of order 6. The action of known group elements now accounts for all the other elements in $Link(I)$.

We indicate briefly how one can construct any isometries which may exist in the stabiliser of M_{19} , in particular, how one can find the element u . This involves an elaboration of the method used in Lemma 1.3.

Suppose that $g \in Isom_J(\Delta)$ has $g[M_{19}] = [M_{19}]$. The definition shows that this is the same as the existence of an element $\alpha \in GL_3(\mathcal{O})$ with $g.M_{19} = M_{19}.\alpha$. The form of the elements M_{19} and g means that α has Laurent polynomial entries. Then

$$\alpha^*(M_{19}^*JM_{19})\alpha = (M_{19}\alpha)^*.J.(M_{19}\alpha) = (g.M_{19})^*.J.(g.M_{19}) = M_{19}^*JM_{19}$$

since g is an isometry. It follows that α is an isometry of the form $M_{19}^*JM_{19}$ and although unlike Lemma 1.3, this form does not have its matrix lying in $GL_3(\mathcal{O})$, we have a bound on the valuations of its entries, so that exactly as in the lemma, we have a bound on the valuations possible for the entries of α . Since we are dealing with a fixed finite field, it follows that there are only a finite number of possibilities for the entries of α and one can check by direct enumeration which of these make $M_{19}\alpha M_{19}^{-1}$ into a J isometry. (In fact sharper, more practical methods exist, but this would take us too far afield.)

We now give some indication of how one can give complete descriptions of all vertex stabilisers. The idea is to work outwards from the identity; it turns out that we need no more elements than those we have already introduced.

Recalling the notation defined above, a calculation shows that that action of u on its link is given by the permutation

$$(7^*)(11^*)(18^*)(23^*)(3^*13^*)(6^*8^*)(14^*24^*26^*)(17^*21^*20^*) \\ (1^*5^*12^*22^*19^*10^*)(4^*16^*25^*15^*2^*9^*)$$

where x^* is shorthand for $M_{19}.x$. The two six cycles consist of 12 group points, ($I = 2^*$), there are 14 points in the orbit of M_{19} and two remaining, as yet

unidentified points, 7^* and 11^* . Points in the orbit of M_{19} we refer to as n -points. Observe that neither of the unidentified points can be group points as they contain an element of order 6 in their stabiliser.

Using this information we now show:

Lemma 2.2 *The group $stab_J(M_{19})$ acts on Δ as a finite group $\mathbf{Z}_6 \cong \langle u \rangle$.*

Sketch of Proof First consider the map $i_0: stab_J(M_{19}) \rightarrow Aut(Link(M_{19}))$. We begin by noting that this map is injective, for any element of the kernel must fix every vertex in $Link(M_{19})$, in particular the vertex I , so that the kernel can only consist of powers of the element x . However, one checks that no element of the group $\langle x \rangle$ other than the identity fixes M_{19} proving the assertion.

We refer to the above permutation, where we recall the vertex 2^* is the identity vertex. Pick an element $\gamma \in stab_J(M_{19})$; it is type-preserving so that it must map the group points in $Link(M_{19})$ which correspond to lines back to lines, and those which correspond to planes to planes. Since u acts transitively on this orbit, we can find some power of u so that $u^k \cdot \gamma$ fixes the vertex 2^* . Now exactly as in the previous paragraph, we deduce that $u^k \cdot \gamma = I$, so that γ is a power of u as required. \square

We now analyse the two new points 7^* and 11^* . We have already shown that these are not group points; we now show that they are not n -points.

Firstly, one finds that $xyx(7^*) = 11^*$, so that this is only one orbit of point and moreover that u acts as an element of order two on $Link(7^*)$. Moreover, we can construct a potentially new element in $stab_J(7^*)$ namely $u_1 = (xyx)^{-1} \cdot u \cdot xyx$. A calculation reveals that the action of the group $\langle u, u_1 \rangle$ on $Link(7^*)$ is the dihedral group D_3 . It now follows from 1.5 and 2.2 that the orbit of 7^* is distinct from that of the group and n -points.

In fact, the stabiliser is larger than this and one finds that there is an element $h \in \langle x, y, u \rangle$ of order 3 which commutes with this dihedral group.

$$h = \begin{pmatrix} 1 + t^4 & 1 + t^2 + t^4 & 1 + t + 2t^2 + 2t^3 \\ 2t + 2t^2 + 2t^4 & 2 + t^2 + 2t^4 & 2 + 2t + t^2 + t^3 \\ 0 & 0 & 2t^2 \end{pmatrix}$$

We omit the arguments which identify the stabilisers of these two points, as this is slightly special, however the results are that one shows successively:

Lemma 2.3 *The map $i_1: stab_J(7^*) \rightarrow Aut(Link(7^*))$ has $im(i_1) \cong \mathbf{Z}_3 \times D_3$.*

Corollary 2.4 *The group $stab_J(7^*)$ has order 54 with structure given by the nonsplit central extension:*

$$1 \rightarrow \langle u^2 \rangle \cong \mathbf{Z}_3 \rightarrow stab_J(7^*) \rightarrow \mathbf{Z}_3 \times D_3 \rightarrow 1$$

The orbit type for the action of $stab_J(7^*)$ acting on its stabiliser is $\{9, 9, 3, 3, 1, 1\}$ where the orbits of size 9 are n -points, the orbits of size 3 are of type 7^* and there are two points as yet unaccounted for, namely $M_{19}.M_7.M_7$ and $M_{19}.M_7.M_{11}$ for which we adopt the notational shorthand $7^{(2)}$ and $11^{(2)}$. As above, $xyx(7^{(2)}) = 11^{(2)}$.

This is the point at which the behaviour stabilises. For later use, it is more convenient to define for $i \geq 0$, a sequence of elements $\alpha_{i+1} = (xyx)^{-i}u.u_1(xy x)^i$. Then we have:

Theorem 2.5 *For $k \geq 2$, the map $i_k: stab_J(7^{(k)}) \rightarrow Aut(Link(7^{(k)}))$ has image of order 54.*

Moreover, $stab_J(7^{(k)})$ is generated by the elements $u, h, \alpha_1, \dots, \alpha_k$.

Sketch Proof The argument is inductive; we explain the step $k = 2$ which contains all the essential ingredients. We set $H(2) = \langle u, \alpha_1, \alpha_2 \rangle \leq stab_J(7^{(2)})$. Note that every element of $H(2)$ stabilises $7^{(3)}$ and $11^{(3)}$. We refer to Figure 1, which shows the hexagon $Link(7^{(2)})/H(2)$. Our claim is that no element of $\eta \in stab_J(7^{(2)})$ can move $7^{(3)}$.

Figure 1

We argue as follows. Note that since elements in vertex stabilisers are type preserving, the only possibilities for $\eta(7^{(3)})$ (assuming that it is moved) are the $H(2)$ orbit of $1^{(3)}$ or the $H(2)$ orbit of $3^{(3)}$.

However, the former orbit contains 9 elements and the latter 3, so that in any case, η must move some element in the $H(2)$ orbit of $1^{(3)}$ back into this orbit. By composing with an element of $H(2)$, we see that this implies the existence of an element moving $7^{(3)}$ lying in $stab_J(k^{(3)}) \cap im(i_2)$ where $k^{(3)}$ lies in the $H(2)$ orbit of $1^{(3)}$. After conjugating by an element of $H(2)$, we may assume that this element lies in $stab_J(1^{(3)}) = (xyx)^{-1}stab_J(2^{(3)})xyx$. But $2^{(3)} = 7^*$, so that $stab_J(1^{(3)}) = (xyx)^{-1}stab_J(7^*)xyx$. An examination of the generating elements shows that no element of this latter group moves $7^{(3)}$, a contradiction. A similar argument establishes that $stab_J(7^{(2)})$ stabilises $11^{(3)}$.

We now show that $im(i_2)$ is a group of order at most 54. The reason is this: All of $im(i_2)$ stabilises $7^{(3)}$ hence permutes the four points in the link adjacent to it, however one of these points is $11^{(3)}$, which is also fixed by the whole group. Therefore by passing to a subgroup of $im(i_2)$ of index at most 3 we stabilise the point $3^{(3)}$. Arguing similarly for $3^{(3)}$, we deduce that $im(i_2)$ contains a subgroup of index at most 9 which stabilises $2^{(3)} = 7^*$. This is a group whose structure is already completely determined and one finds that $stab_J(7^*)$ acts on $Link(7^{(2)})$ as a group of order 6, proving the claim.

Now the group $H(2)$ is easily analysed; in particular, one shows easily that it acts on the link as a group of order 54. This establishes that $i_2(H(2)) = im(i_2)$ as required.

The kernel of the map $i_2: stab_J(7^{(2)}) \rightarrow Aut(Link(7^{(2)}))$ is a subgroup of $stab_J(7^*)$. Recalling that $H(2)$ is generated by u , α_1 and α_2 , it follows that u , h , α_1 and α_2 generate $stab(7^{**})$, completing the first step of the induction. \square

Given this theorem, one can now give a complete description of the groups $stab_J(7^{(k)})$ by analysing how $ker(i_k) \leq stab_J(7^{(k-1)})$ acts on $Link(7^{(k)})$. As a consequence, one proves that the group $stab_J(7^{(k)})$ has order $2 \cdot 3^{2k+1}$. It follows immediately that the orbits $7^{(k)}$ are all distinct.

We recap our progress so far. From the information that the stabiliser of the lattice I is a cyclic group of order four, we have identified the stabiliser of every vertex in the building; this information suffices to deduce that the orbits for the action of $Isom_J(\Delta)$ on Δ are precisely $I, M_{19}, 7^{(k)}$ for $k \geq 1$. Moreover, this already shows:

Corollary 2.6 *The group $Isom_J(\Delta)$ is generated by x , y and u .*

The construction of the entire complex $\Delta/Isom_J(\Delta)$ rests largely on the work set forth above and we shall not go into it in detail. Broadly it involves two steps: The identification of a candidate set of orbits of edges and triangles coming from the action of fairly short elements, followed by the proof that no further identifications are possible. This latter step is accomplished by the detailed understanding we have developed of the vertex stabilisers. This task gets easier as one moves further away from the group points, as stabilisers get larger and there are less orbits to be considered; eventually the action of stabilisers on links becomes constant. As a result, the complex has a fairly natural decomposition into two pieces; a compact part and some “tubes”. We refer the reader to [3] for details in the case $p = 2$. For example, a picture of the tube comes from the concatenation of hexagons shown in Figure 2.

Figure 2

3 The case $p = 5$

The analysis in this case follows the same outline as indicated above, though of course the details become much more complicated. Nonetheless, one obtains a presentation of the group $Isom_J(\Delta(5))$. The quotient complex has interesting features not present in the first two cases; for example in contrast to the cases $p = 2$ and $p = 3$, the complex which emerges has three annular ends.

Once again one finds extra elements in $Isom_J(\Delta(5))$ which it turns out do not

lie in the group generated by x and y . The simplest of these is the element β_2 shown below:

$$\beta_2 = \begin{pmatrix} 4 & 1 + 2t + 2t^2 & 3 + t \\ 1 + t & 4 + 2t & 2 + 2t \\ 1 & 4 + 3t + 4t^2 & 2 + 2t \end{pmatrix}$$

This is an element of order 4 and one finds that:

Theorem 3.1 *The group $Isom_J(\Delta(5))$ is generated by x , y and β_2*

In fact, we are able to complete all the analysis up until the very last step and in particular, we are able to find a presentation of the group $Isom_J(\Delta(5))$. It is rather complicated and *GAP* was unable to show that the index $[Isom_J(\Delta(5)) : \langle x, y \rangle]$ was finite. We have been unable to prove that it is infinite and unable to analyse the situation sufficiently to prove or disprove that $\langle x, y \rangle$ contains no extra relations.
