We introduce new types of distance Fibonacci numbers which are closely related with number decompositions. Using special decompositions of the number  $n$  we give a sequence of identities for them. Moreover, we give matrix generators for distance Fibonacci numbers and their direct formulas.

## 1. Introduction

The  $n$ th Fibonacci numbers  $F_n$  are defined by recurrence relation  $F_n = F_{n-1} + F_{n-2}$ ,  $n \geq 2$  with the initial conditions  $F_0 = F_1 = 1$ . There are many generalizations of the Fibonacci numbers  $F_n$  with respect to one or more parameters; see for example [1–3]. In [1] the distance Fibonacci numbers  $Fd^{(1)}(k, n)$  were introduced and studied. We recall this definition.

Let  $k \geq 2$ ,  $n \geq 0$  be integers. The distance Fibonacci numbers of the first kind  $Fd^{(1)}(k, n)$  are defined recursively in the following way:

$$Fd^{(1)}(k, n) = Fd^{(1)}(k, n - k + 1) + Fd^{(1)}(k, n - k) \quad \text{for } n \geq k, \quad (1)$$

and  $Fd^{(1)}(k, n) = 1$  for  $n = 0, \dots, k - 1$ .

We will call the numbers  $Fd^{(1)}(k, n)$  the distance Fibonacci numbers of the first kind. The number  $Fd^{(1)}(k, n)$  is closely related to the special quasi  $k$ -decomposition of the number  $n$ ; see [1].

In this paper we define other three types of distance Fibonacci numbers which are also related to the special number decomposition. Moreover we shall show relations between all three types of distance Fibonacci numbers. Next we study their matrix generators and direct formulas.

## 2. Distance Fibonacci Numbers

### $Fd^{(2)}(k, n)$ and $Fd^{(3)}(k, n)$

In this section we introduce two kinds of distance Fibonacci numbers. Some relations between numbers  $Fd^{(i)}(k, n)$  for  $i = 1, 2, 3$  will be studied.

Let  $k \geq 2$ ,  $n \geq 0$  be integers. We define the  $n$ th distance Fibonacci numbers of the second kind  $Fd^{(2)}(k, n)$  by the  $k$ th order linear recurrence relation of the form

$$Fd^{(2)}(k, n) = Fd^{(2)}(k, n - k + 1) + Fd^{(2)}(k, n - k) \quad \text{for } n \geq k, \quad (2)$$

with the initial conditions

$$Fd^{(2)}(k, n) = 0 \quad \text{for } n = 0, \dots, k - 2,$$

$$Fd^{(2)}(k, k - 1) = 1,$$

$$Fd^{(2)}(1, 1) = 1,$$

$$Fd^{(2)}(2, 2) = 2,$$

$$Fd^{(2)}(k, k) = 1, \quad \text{for } k \geq 3.$$

If  $k = 2$ ,  $n \geq 1$ , then  $Fd^{(2)}(k, n)$  gives the Fibonacci numbers  $F_n$ .

Let  $k \geq 2, n \geq 0$  be integers. We define the  $n$ th distance Fibonacci numbers of the third kind  $Fd^{(3)}(k, n)$  by the  $k$ th order linear recurrence relation of the form

$$Fd^{(3)}(k, n) = Fd^{(3)}(k, n - k + 1) + Fd^{(3)}(k, n - k) \quad \text{for } n \geq 2k - 1, \tag{3}$$

with the initial conditions

$$Fd^{(3)}(k, n) = 1 \text{ for } n = 0, \dots, k - 1,$$

$$Fd^{(3)}(2, 2) = 2,$$

$$\text{for } k \geq 3 \quad Fd^{(3)}(k, k) = 3 = Fd^{(3)}(k, 2k - 2),$$

$$\text{for } k + 1 \leq n \leq 2k - 3 \quad Fd^{(3)}(k, n) = 4.$$

If  $k = 2$ , then  $Fd^{(3)}(k, n)$  gives the classical Fibonacci numbers.

Now we give an interpretation of the numbers  $Fd^{(1)}(k, n)$ ,  $Fd^{(2)}(k, n)$ , and  $Fd^{(3)}(k, n)$  with respect to special decompositions of the number  $n$ .

By a decomposition of a number  $n, n \geq 1$ , we mean an ordered number partition of it. For example for  $n = 3$  we have the following four decompositions:  $1 + 1 + 1, 2 + 1, 1 + 2$ , and  $3$ . In this paper we study special decompositions of a number  $n$  which are closely related to distance Fibonacci numbers  $Fd^{(i)}(k, n)$ , for  $i = 1, 2, 3$ .

Let  $1 \leq r \leq k - 2$  be a fixed integer. A decomposition of the number  $n \geq k - 1$  of the form  $r + n_1 + n_2 + \dots + n_p$  (resp.,  $n_1 + n_2 + \dots + n_p + r$ ) where  $n_i \in \{k, k - 1\}, i = 1, \dots, p$  is called an  $r_-k$ -decomposition (resp.,  $r_+k$ -decomposition). We denote the number of all  $r_-k$ -decompositions (resp.,  $r_+k$ -decompositions) by  $\sigma_{-r}(k, n)$  (resp.,  $\sigma_{+r}(k, n)$ ). Clearly

$$\sigma_{-r}(k, n) = \sigma_{+r}(k, n). \tag{4}$$

A decomposition of the number  $n \geq k - 1$  of the form  $n_1 + n_2 + \dots + n_p$ , where  $n_i \in \{k, k - 1\}, i = 1, \dots, p$ , is called a  $k$ -decomposition. We denote the number of all  $k$ -decompositions by  $\sigma_0(k, n)$ .

Let  $0 \leq r_0 \leq k - 2$  be a fixed integer. A decomposition of the number  $n \geq k - 1$  of the form  $r_0 + n_1 + n_2 + \dots + n_p$  (resp.,  $n_1 + n_2 + \dots + n_p + r_0$ ) where  $n_i \in \{k, k - 1\}, i = 1, \dots, p$  is called an  $r_0_-k$ -decomposition (resp.,  $r_0_+k$ -decomposition). Consequently as the above we denote the number of all  $r_0_-k$ -decompositions (resp.,  $r_0_+k$ -decompositions) by  $\sigma_{-r_0}(k, n)$  (resp.,  $\sigma_{+r_0}(k, n)$ ). Clearly for  $r_0 = 0$  a  $0_-k$ -decomposition of  $n$  is a  $k$ -decomposition and for  $r_0 \geq 1$  an  $r_0_-k$ -decomposition (resp.,  $r_0_+k$ -decompositions) is an  $r_-k$ -decompositions (resp.,  $r_+k$ -decompositions). From the above definitions immediately follow relations between

numbers  $\sigma_{-r}(k, n), \sigma_{-r_0}(k, n)$ , and  $\sigma_0(k, n)$  (resp.,  $\sigma_{+r}(k, n), \sigma_{+r_0}(k, n)$ , and  $\sigma_0(k, n)$ ):

$$\sigma_{-r_0}(k, n) = \sum_{r=1}^{k-2} \sigma_{-r}(k, n) + \sigma_0(k, n), \tag{5}$$

$$\sigma_{+r_0}(k, n) = \sum_{r=1}^{k-2} \sigma_{+r}(k, n) + \sigma_0(k, n), \tag{6}$$

$$\sigma(k, n) = \sum_{j=-(k-2)}^{k-2} \sigma_j(k, n). \tag{7}$$

**Theorem 1** (see [1]). *Let  $k \geq 2, n \geq k - 1$  be integers. Then  $\sigma_{+r_0}(k, n) = Fd^{(1)}(k, n)$ .*

For the proof of the next theorem we will need the following lemma.

**Lemma 2.** *Let  $k \geq 2, n \geq k - 1$  be integers. Then*

$$2Fd^{(1)}(k, n) - Fd^{(2)}(k, n) = Fd^{(3)}(k, n), \tag{8}$$

for  $n \geq k - 1$ .

*Proof.* If  $n = k - 1$ , then the equality immediately follows. Assume that the lemma is true for an arbitrary  $t < n$  and we prove it for  $n$ . Using the definitions of numbers  $Fd^{(1)}(k, n)$  and  $Fd^{(2)}(k, n)$  we obtain that  $2Fd^{(1)}(k, n) - Fd^{(2)}(k, n) = 2Fd^{(1)}(k, n - k) + 2Fd^{(1)}(k, n - k + 1) - Fd^{(2)}(k, n - k) - Fd^{(2)}(k, n - k + 1) = Fd^{(3)}(k, n)$  by the induction's hypothesis.  $\square$

We can write the above lemma also in the following form.

**Corollary 3.** *Let  $k \geq 2, n \geq k - 1$  be integers. Then*

$$Fd^{(1)}(k, n) - Fd^{(2)}(k, n) = Fd^{(3)}(k, n) - Fd^{(1)}(k, n). \tag{9}$$

**Theorem 4.** *Let  $k \geq 2, n \geq 1, 1 \leq r \leq k - 2$  be integers. Then*

$$(i) \quad \sigma_{-r_0}(k, n) = \sigma_{+r_0}(k, n) = Fd^{(1)}(k, n),$$

$$(ii) \quad \sigma_0(k, n) = Fd^{(2)}(k, n),$$

$$(iii) \quad \sigma(k, n) = Fd^{(3)}(k, n).$$

*Proof.* The equality (i) follows immediately by Theorem 1 and (4).

We shall show that  $\sigma_0(k, n) = Fd^{(2)}(k, n)$ . If  $n = 1, 2, \dots, k - 2$ , then there is no  $k$ -decomposition of the number  $n$  into parts  $k - 1$  and  $k$ . So  $\sigma_0(k, n) = 0 = Fd^{(2)}(k, n)$ . If  $n = k - 1, k$ , then there is a unique  $k$ -decomposition of the number  $n$ ; hence  $\sigma_0(k, n) = 1 = Fd^{(2)}(k, n)$ . Let  $n \geq k + 1$ . Assume that the equality holds for an arbitrary  $t < n$ . We shall show that  $\sigma_0(k, n) = Fd^{(2)}(k, n)$ . Let  $n = n_1 + n_2 + \dots + n_p$  be a  $k$ -decomposition of the number  $n$  into parts  $k$  and  $k - 1$ . If  $n_p = k$ , then  $n = n_1 + n_2 + \dots + n_{p-1} + k$  so  $n - k = n_1 + n_2 + \dots + n_{p-1}$ . By induction's hypothesis there are  $Fd^{(2)}(k, n - k)$   $k$ -decompositions in this case. If  $n_p = k - 1$  then proving analogously we obtain  $Fd^{(2)}(k, n - k + 1)$   $k$ -decompositions

of the form  $n = n_1 + n_2 + \dots + n_{p-1} + k - 1$ . From the above we have  $Fd^{(2)}(k, n - k) + Fd^{(2)}(k, n - k + 1)$   $k$ -decompositions of the number  $n$  into parts  $k$  and  $k - 1$ , and by the definition of  $Fd^{(2)}(k, n)$  it follows that  $\sigma_0(k, n) = Fd^{(2)}(k, n)$ .

Now we shall prove that  $\sigma(k, n) = Fd^{(3)}(k, n)$ . From the definition of  $\sigma(k, n)$  we obtain that

$$\begin{aligned} \sigma(k, n) &= \sum_{j=-(k-2)}^{k-2} \sigma_j(k, n) \\ &= 2 \sum_{r=1}^{k-2} \sigma_{+r}(k, n) + \sigma_0(k, n) \\ &= Fd^{(1)}(k, n) \\ &\quad + \sum_{r=1}^{k-2} \sigma_{+r}(k, n) + \sigma_0(k, n) - \sigma_0(k, n) \\ &= 2Fd^{(1)}(k, n) - Fd^{(2)}(k, n), \end{aligned} \tag{10}$$

by the statements (i) and (ii) of this theorem.

Then the statement (iii) follows immediately by Lemma 2, which ends the proof.  $\square$

**Theorem 5.** Let  $k \geq 2, n \geq k - 1$  and  $1 \leq r \leq k - 2$  be integers. Then

$$\sigma_{-r}(k, pk + i) = 2^p, \tag{11}$$

for natural  $p$  and  $i = 1, 2, \dots, k - (p + 2)$ .

*Proof.* Let  $p$  be natural and  $i = 1, 2, \dots, k - (p + 2)$ . The number  $pk + i$  is equal to  $(i + l) + l \cdot (k - 1) + (p - l) \cdot k$ , for  $l = 0, 1, \dots, p$ , and all  $r$ - $k$ -decompositions of  $pk + i$  have the form  $(i + l) + n_1 + \dots + n_p$ . We can put  $k - 1$  on  $l$  positions, so we have  $\binom{p}{l}$  possibilities. The sum  $\sum_{l=0}^p \binom{p}{l}$  is equal to  $2^p$  which ends the proof.  $\square$

Now we give applications of distance Fibonacci numbers for counting of the number of other special decompositions of the number  $n$ .

Let  $k \geq 2, n \geq k$  be integers and let  $\sigma_{\pm r_0}(k, n)$  be the numbers of all decomposition of the number  $n = n_1 + n_2 + \dots + n_p$ , where  $n_i \in \{k, k - 1\}$ , for  $i = 2, \dots, p - 1$  and  $n_1, n_p \in \{1, \dots, k\}$ .

**Theorem 6.** Let  $k \geq 2, n \geq k$  be integers. Then

$$\sigma_{\pm r_0}(k, n) = \sum_{r=1}^k Fd^{(1)}(k, n - r). \tag{12}$$

*Proof.* Let  $n = n_1 + n_2 + \dots + n_p$  be a decomposition of the number  $n$ , where  $n_i \in \{k, k - 1\}$ , for  $i = 2, \dots, p - 1$  and  $n_1, n_p \in \{1, \dots, k\}$ . Then  $n - n_p = n_1 + n_2 + \dots + n_{p-1}$ , where  $n_1 + n_2 + \dots + n_{p-1}$  is either a  $r$ - $k$ -decomposition or a  $k$ -decomposition of the number  $n - n_p$ . Since  $n_p \in \{1, \dots, k\}$  by Theorem 4(i) it follows that  $\sigma_{\pm r_0}(k, n) = \sum_{r=1}^k Fd^{(1)}(k, n - r)$ , which ends the proof.  $\square$

**Theorem 7.** Let  $k \geq 3, n \geq k$  be integers. Then

$$\begin{aligned} &\sum_{i=1}^{k-2} \sum_{j=1}^{k-2} Fd^{(2)}(k, n - (i + j)) \\ &= \sum_{i=1}^{k-2} (Fd^{(1)}(k, n - i) - Fd^{(2)}(k, n - i)), \end{aligned} \tag{13}$$

for natural  $p$  and  $i = 1, 2, \dots, k - (p + 2)$ .

*Proof.* Let  $k \geq 2, n \geq k$  be integers. Let  $n = n_1 + n_2 + \dots + n_p$  be a decomposition  $\eta$  of the number  $n$ , where  $n_i \in \{k, k - 1\}$ , for  $i = 2, \dots, p - 1$  and  $n_1, n_p \in \{1, \dots, k - 2\}$ . Then the number of such decomposition is equal to the number of  $k$ -decomposition of the number  $n - (n_1 + n_p)$ . By Theorem 4(ii) we obtain that we have  $Fd^{(2)}(k, n - (n_1 + n_p))$  decompositions  $\eta$ . Since  $n_1, n_p \in \{1, \dots, k - 2\}$  it is clear that totally we have

$$\sum_{i=1}^{k-2} \sum_{j=1}^{k-2} Fd^{(2)}(k, n - (i + j)) \tag{14}$$

decompositions of the number  $n$ .

On the other hand, we have that the total number of decompositions  $\eta$  is equal to the number of  $r$ - $k$ -decompositions of the number  $n - n_p$ . Since  $n_p \in \{1, \dots, k - 2\}$  by formula (5) and Theorem 4 we obtain

$$\sum_{i=1}^{k-2} (Fd^{(1)}(k, n - i) - Fd^{(2)}(k, n - i)). \tag{15}$$

From the above it immediately follows that

$$\begin{aligned} &\sum_{i=1}^{k-2} \sum_{j=1}^{k-2} Fd^{(2)}(n - (i + j)) \\ &= \sum_{i=1}^{k-2} (Fd^{(1)}(k, n - i) - Fd^{(2)}(k, n - i)), \end{aligned} \tag{16}$$

which ends the proof.  $\square$

### 3. Identities for $Fd^{(1)}(k, n)$ , $Fd^{(2)}(k, n)$ , and $Fd^{(3)}(k, n)$

In this section we give some identities for distance Fibonacci numbers:  $Fd^{(i)}(k, n)$ , for  $i = 1, 2, 3$ .

**Theorem 8.** Let  $k \geq 2, n \geq k$  be integers. Then

$$\begin{aligned} &\sum_{j=1}^3 a_j Fd^{(j)}(k, n) \\ &= \sum_{i=0}^p \binom{p}{i} \left( \sum_{j=1}^3 a_j Fd^{(j)}(k, n - pk + i) \right). \end{aligned} \tag{17}$$

*Proof (by induction on n).* For  $n = k$  we have  $p = 1$  and

$$\begin{aligned}
 & \sum_{j=1}^3 a_j Fd^{(j)}(k, k) \\
 &= \sum_{j=1}^3 a_j (Fd^{(j)}(k, k-k) + Fd^{(j)}(k, k-k+1)) \\
 &= \sum_{j=1}^3 a_j (Fd^{(j)}(k, 0) + Fd^{(j)}(k, 1)) \\
 &= \sum_{j=1}^3 a_j (Fd^{(j)}(k, k-1 \cdot k+0) \\
 & \quad + Fd^{(j)}(k, k-1 \cdot k+1)) \\
 &= \sum_{i=0}^1 \binom{1}{i} \sum_{j=1}^3 a_j Fd^{(j)}(k, i).
 \end{aligned} \tag{18}$$

Let  $n > k$ . Assume that (17) is true for arbitrary  $t < n$  and we prove it for  $n$ . Using induction's assumption for  $t = n - k$  and  $t = n - k + 1$  we have

$$\begin{aligned}
 & Fd^{(j)}(k, n) \\
 &= Fd^{(j)}(k, n-k) + Fd^{(j)}(k, n-k+1) \\
 &= \sum_{i=0}^p \binom{p}{i} Fd^{(j)}(k, n-k-pk+i) \\
 & \quad + \sum_{i=0}^p \binom{p}{i} Fd^{(j)}(k, n-k+1-pk+i) \\
 &= \sum_{i=0}^p \binom{p}{i} [Fd^{(j)}(k, n-k-pk+i) \\
 & \quad + Fd^{(j)}(k, n-k+1-pk+i)] \\
 &= \sum_{i=0}^p \binom{p}{i} [Fd^{(j)}(k, n-pk+i-k) \\
 & \quad + Fd^{(j)}(k, n-pk+i-k+1)] \\
 &= \sum_{i=0}^p \binom{p}{i} Fd^{(j)}(k, n-pk+i),
 \end{aligned}$$

which ends the proof.

**Corollary 9.** Let  $k \geq 2, n \geq k$  be integers. Then

- (iv)  $Fd^{(1)}(k, n) = \sum_{i=0}^p \binom{p}{i} Fd^{(1)}(k, n-pk+i)$ ,
- (v)  $Fd^{(2)}(k, n) = \sum_{i=0}^p \binom{p}{i} Fd^{(2)}(k, n-pk+i)$ ,
- (vi)  $Fd^{(3)}(k, n) = \sum_{i=0}^p \binom{p}{i} Fd^{(3)}(k, n-pk+i)$ .

*Proof.* (iv) This formula directly follows from Theorem 8 putting  $a_1 = 1$  and  $a_2 = a_3 = 0$ . For (v) and (vi) analogously.  $\square$

**Theorem 10.** Let  $k \geq 3, n \geq k$  be integers. Then

$$Fd^{(1)}(k, n) = \sum_{i=0}^{k-2} Fd^{(2)}(k, n-i). \tag{20}$$

*Proof (by induction on n).* For  $n = k$  we have  $Fd^{(1)}(k, k) = Fd^{(1)}(k, 0) + Fd^{(1)}(k, 1) = 1 + 1 = 2$ . The right side of (20) has the form  $\sum_{i=0}^{k-2} Fd^{(2)}(k, k-i) = Fd^{(2)}(k, k-0) + Fd^{(2)}(k, k-1) + Fd^{(2)}(k, k-2) + \dots + Fd^{(2)}(k, k-(k-2)) = Fd^{(2)}(k, k) + Fd^{(2)}(k, k-1) + Fd^{(2)}(k, k-2) + \dots + Fd^{(2)}(k, 2) = 1 + 1 + 0 + \dots + 0 = 2$ .

Let  $n > k$ . Assume that (20) is true for arbitrary  $t < n$  and we prove it for  $n$ . Using induction's assumption for  $t = n - k$  and  $t = n - k + 1$  we have

$$\begin{aligned}
 & Fd^{(1)}(k, n) \\
 &= Fd^{(1)}(k, n-k) + Fd^{(1)}(k, n-k+1) \\
 &= \sum_{i=0}^{k-2} Fd^{(2)}(k, n-k-i) \\
 & \quad + \sum_{i=0}^{k-2} Fd^{(2)}(k, n-k+1-i) \\
 &= \sum_{i=0}^{k-2} [Fd^{(2)}(k, n-k-i) \\
 & \quad + Fd^{(2)}(k, n-k+1-i)] \\
 &= \sum_{i=0}^{k-2} [Fd^{(2)}(k, n-i-k) \\
 & \quad + Fd^{(2)}(k, n-i-k+1)] \\
 &= \sum_{i=0}^{k-2} Fd^{(2)}(k, n-i),
 \end{aligned} \tag{21}$$

which ends the proof.  $\square$

**4. Matrix Generators and Combinatorial Formulas for  $Fd^{(1)}(k, n)$ ,  $Fd^{(2)}(k, n)$ , and  $Fd^{(3)}(k, n)$**

$\square$  Matrix methods are important in recurrence relations. In the last decades some mathematicians have studied to find miscellaneous affinities between matrices and linear recurrences. Using matrix methods different identities and algebraic representations of considered sequences can be obtained, for instance [1, 2, 4-6]. Theory of Fibonacci numbers was previously complemented by the theory of so-called the Fibonacci Q-matrix or the golden matrix. It is worth mentioning that

the American mathematician V. Hoggat was one of the first mathematicians who paid the attention to the  $Q$ -matrix. For the classical Fibonacci sequence the matrix generators, named as the golden matrix, have the form  $Q = \begin{bmatrix} 1 & 1 \\ 1 & 0 \end{bmatrix}$  and  $Q^n = \begin{bmatrix} F_{n+1} & F_n \\ F_n & F_{n-1} \end{bmatrix}$ , for  $n \geq 1$ .

Golden number and golden section have many interesting applications in different areas of science (physics, chemistry, and mechanics); see for example [7, 8]. In this section we give the matrix generators for distance Fibonacci numbers  $Fd^{(i)}(k, n)$ , where  $i = 1, 2, 3$ . The matrix generator of the distance Fibonacci numbers of the first kind  $Fd^{(1)}(k, n)$  was introduced in [1] and in this paper we apply this method for all kinds of distance Fibonacci numbers.

Let  $k \geq 2$  be a fixed integer. Let  $Q_k = [q_{ij}]$  be a square matrix of size  $k$ . For a fixed  $1 \leq t \leq k$  an element  $q_{t1}$  is equal to the coefficient of  $Fd^{(i)}(k, n - t)$  in the recurrence formula for the distance Fibonacci numbers  $Fd^{(i)}(k, n)$ ,  $i = 1, 2, 3$ . For  $j \geq 2$  we define  $q_{ij}$  as follows:

$$q_{ij} = \begin{cases} 1 & \text{if } j = t + 1 \\ 0 & \text{otherwise.} \end{cases} \quad (22)$$

In other words,

$$Q_2 = \begin{bmatrix} 1 & 1 \\ 1 & 0 \end{bmatrix},$$

$$Q_3 = \begin{bmatrix} 0 & 1 & 0 \\ 1 & 0 & 1 \\ 1 & 0 & 0 \end{bmatrix}, \dots, Q_k = \begin{bmatrix} 0 & 1 & 0 & \dots & 0 \\ 0 & 0 & 1 & \dots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & 0 & 0 & \dots & 1 \\ 1 & 0 & 0 & \dots & 0 \end{bmatrix}, \quad (23)$$

and the matrix  $Q_k$  is named as the distance Fibonacci matrix or the generator of the distance Fibonacci numbers  $Fd^{(i)}(k, n)$ ,  $i = 1, 2, 3$ .

For a fixed  $1 \leq i \leq 3$  we define the square matrix  $A_k^{(i)}$  of size  $k$  named as the matrix of initial conditions of the form

$$A_k^{(i)} = \begin{bmatrix} Fd^{(i)}(k, 2k - 2 + u(i)) & Fd^{(i)}(k, 2k - 3 + u(i)) & \dots & Fd^{(i)}(k, k - 1 + u(i)) \\ Fd^{(i)}(k, 2k - 3 + u(i)) & Fd^{(i)}(k, 2k - 4 + u(i)) & \dots & Fd^{(i)}(k, k - 2 + u(i)) \\ \vdots & \vdots & \ddots & \vdots \\ Fd^{(i)}(k, k + u(i)) & Fd^{(i)}(k, k - 1 + u(i)) & \dots & Fd^{(i)}(k, 1 + u(i)) \\ Fd^{(i)}(k, k - 1 + u(i)) & Fd^{(i)}(k, k - 2 + u(i)) & \dots & Fd^{(i)}(k, 0 + u(i)) \end{bmatrix}, \quad (24)$$

where

$$u(i) = \begin{cases} i - 1 & \text{for } i = 1, 2 \\ k - 1 & \text{for } i = 3. \end{cases} \quad (25)$$

**Theorem 11.** Let  $k \geq 2$ ,  $n \geq k$  be integer. Then for a fixed  $1 \leq i \leq 3$  holds

$$A_k^{(i)} Q_k^n = \begin{bmatrix} Fd^{(i)}(k, n + 2k - 2 + u(i)) & Fd^{(i)}(k, n + 2k - 3 + u(i)) & \dots & Fd^{(i)}(k, n + k - 1 + u(i)) \\ Fd^{(i)}(k, n + 2k - 3 + u(i)) & Fd^{(i)}(k, n + 2k - 4 + u(i)) & \dots & Fd^{(i)}(k, n + k - 2 + u(i)) \\ \vdots & \vdots & \ddots & \vdots \\ Fd^{(i)}(k, n + k + u(i)) & Fd^{(i)}(k, n + k - 1 + u(i)) & \dots & Fd^{(i)}(k, n + 1 + u(i)) \\ Fd^{(i)}(k, n + k - 1 + u(i)) & Fd^{(i)}(k, n + k + u(i)) & \dots & Fd^{(i)}(k, n + 0 + u(i)) \end{bmatrix}. \quad (26)$$

Since the proof is analogous as in [1] we omit it. To obtain other matrix generators apart distance Fibonacci numbers  $Fd^{(i)}(k, n)$ ,  $i = 1, 2, 3$ , we define a collection of special sequences which are given by the same  $k$ th order linear recurrence relations as  $Fd^{(i)}(k, n)$ ,  $i = 1, 2, 3$ . These sequences give auxiliary tools for other matrix generators of  $Fd^{(i)}(k, n)$ ,  $i = 1, 2, 3$  and their explicit formulas.

Let  $k \geq 2$ ,  $n \geq 0$  be integers. Let  $\mathcal{F}_k = \{Fd_l^{(4)}(k, n), l = 0, 1, \dots, k - 1\}$ , where  $\{Fd_l^{(4)}(k, n)\}$  is the sequence defined as follows:

$$Fd_l^{(4)}(k, n) = Fd_l^{(4)}(k, n - k + 1) + Fd_l^{(4)}(k, n - k), \quad (27)$$

for  $n \geq k$ ,

with the initial conditions  $Fd_l^{(4)}(k, l) = 1$  and  $Fd_l^{(4)}(k, j) = 0$  for  $j \neq l$ .

The number  $Fd_1^{(4)}(k, n)$  will be also denoted shortly by  $Fd^{(4)}(k, n)$  and named as the  $n$ th distance Fibonacci number of the fourth kind. If  $k = 2$  and  $n \geq 1$ , then  $Fd^{(4)}(2, n) = F_{n-1}$ .

By simple observation we obtain the following relations between numbers  $Fd_l^{(4)}(k, n)$ , for  $l = 0, 1, \dots, k - 1$ :

$$Fd_0^{(4)}(k, n) = Fd^{(4)}(k, n - k + 1), \tag{28}$$

$$Fd_l^{(4)}(k, n) = Fd^{(4)}(k, n - l + 1) \quad \text{for } 2 \leq l \leq k - 1.$$

Using sequences from the collection  $\mathcal{F}_k$  we can generate the distance Fibonacci numbers  $Fd^{(i)}(k, n)$ ,  $i = 1, 2, 3$ :

$$Fd^{(1)}(k, n) = \sum_{l=0}^{k-1} Fd^{(1)}(k, l) Fd_l^{(4)}(k, n) = \sum_{l=0}^{k-1} Fd_l^{(4)}(k, n),$$

$$Fd^{(2)}(k, n) = \sum_{l=k-1}^k Fd^{(2)}(k, l) Fd_{l-1}^{(4)}(k, n - 1)$$

$$= \sum_{l=k-1}^k Fd_{l-1}^{(4)}(k, n - 1) \quad \text{for } n \geq 1,$$

$$Fd^{(3)}(k, n)$$

$$= \sum_{l=0}^{k-1} Fd^{(3)}(k, k - 1 + l) Fd_l^{(4)}(k, n - (k - 1))$$

$$\text{for } n \geq k - 1. \tag{29}$$

**Theorem 12.** Let  $k \geq 2$  be integer. Then

- (i)  $Fd^{(1)}(k, n) = \sum_{t=0}^{k-1} Fd^{(4)}(k, n - t)$  for  $n \geq k$ ,
- (ii)  $Fd^{(2)}(k, n) = Fd^{(4)}(k, n - (k - 2)) + Fd^{(4)}(k, n - (k - 1))$  for  $n \geq k$ ,
- (iii)  $Fd^{(3)}(k, n) = Fd^{(4)}(k, n - 2(k - 1)) + 3Fd^{(4)}(k, n - (k - 1)) + 4 \sum_{t=2}^{k-2} Fd^{(4)}(k, n - (k - 1) - t + 1) + 3Fd^{(4)}(k, n - 2(k - 1) + 1)$  for  $n \geq 2k - 1$ .

*Proof.* Let  $Fd_l^{(1)}(k, n)$  denote a sequence defined by the same recurrence as  $Fd^{(1)}(k, n)$  with initial conditions

$$Fd_l^{(1)}(k, n) = \begin{cases} Fd^{(1)}(k, l) & \text{if } n = l \\ 0 & \text{if } n \neq l \end{cases} \quad \text{for } n \leq k - 1. \tag{30}$$

Then

$$Fd_l^{(1)}(k, n)$$

$$= Fd_0^{(1)}(k, n) + \dots + Fd_{k-1}^{(1)}(k, n)$$

$$= Fd^{(1)}(k, 0) Fd_0^{(1)}(k, n)$$

$$+ \dots + Fd^{(1)}(k, -1) Fd_{k-1}^{(1)}(k, n) \tag{31}$$

$$= 1 Fd_0^{(1)}(k, n) + \dots + 1 Fd_{k-1}^{(1)}(k, n)$$

$$= \sum_{t=0}^{k-1} Fd^{(4)}(k, n - t).$$

We prove analogously formulas (ii) and (iii). □

Using the above theorem we obtain a new matrix generator for distance Fibonacci numbers  $Fd^{(i)}(k, n)$ ,  $i = 1, 2, 3$ .

**Corollary 13.** For the distance Fibonacci numbers  $Fd^{(i)}(k, n)$ ,  $i = 1, 2, 3$ , Theorem 12 gives its matrix generator, respectively:

- (1)  $\sum_{t=0}^{k-1} Q_k^{n-t}$  for  $n \geq k$ ,
- (2)  $Q_k^{n-(k-2)} + Q_k^{n-(k-1)}$  for  $n \geq k$ ,
- (3)  $Q_k^{n-2(k-1)} + 3Q_k^{n-(k-1)} + 4 \sum_{t=2}^{k-2} Q_k^{n-(k-1)-t+1} + Q_k^{n-2(k-1)+1}$  for  $n \geq 2k - 1$ .

**Theorem 14.** Let  $k \geq 2, n \geq k$  be integer. Then

$$Fd^{(4)}(k, n + 1) = \sum_{\substack{k_1, k_2 \\ k_1 + k_2 = (k-1) = n}} \binom{k_1 + k_2}{k_1}. \tag{32}$$

*Proof.* We consider a digraph  $D_k$  represented by adjacency matrix  $Q_k$  auxiliary (Figure 1).

Note that matrix  $Q_k^n$  has the following form:

$$\begin{bmatrix} Fd^{(4)}(k, n + 1) & Fd^{(4)}(k, n) & \dots & Fd^{(4)}(k, n - (k - 2)) \\ Fd^{(4)}(k, n + 2) & Fd^{(4)}(k, n + 1) & \dots & Fd^{(4)}(k, n - (k - 1)) \\ \vdots & \vdots & \ddots & \vdots \\ Fd^{(4)}(k, n + (k - 1)) & Fd^{(4)}(k, n + (k - 2)) & \dots & Fd^{(4)}(k, n) \\ Fd^{(4)}(k, n) & Fd^{(4)}(k, n - 1) & \dots & Fd^{(4)}(k, n - (k - 1)) \end{bmatrix}. \tag{33}$$

It is well known that  $q_{ij} \in Q_k^n$  is equal to the number of all distinct paths of length  $n$  between vertices  $v_i$  and  $v_j$  in the digraph  $D_k$ .

Each path  $P$  from  $v_1$  to  $v_1$  in digraph  $D_k$  has the following form:  $P : v_1 \rightsquigarrow v_{x_1} \rightarrow v_1 \rightsquigarrow v_{x_2} \rightarrow v_1 \dots v_1 \rightsquigarrow v_{x_i} \rightarrow v_1$  where  $v_1 \rightsquigarrow v_x$  denotes the unique shortest path from  $v_1$  to  $v_x$  in

TABLE 1: The  $n$ th distance Fibonacci numbers  $Fd^{(1)}(k, n)$ .

$Fd^{(2)}(8, n)$	0	0	0	0	0	0	0	1	1	0	0	0	0	0	1

FIGURE 1: A digraph  $D_k$ .

digraph  $D_k$ . Parts  $v_1 \rightarrow v_x \rightarrow v_1$  are cycles of the length  $x$ , where  $x$  is  $k$  or  $k - 1$ . Thus the length of the path  $P$  is equal to  $x_1 + x_2 + \dots + x_i$ . There exists one-to-one correspondence between the path  $P$  and a tuple  $(x_1, x_2, \dots, x_i)$ . If the path  $P$  has a length  $n$ , then the corresponding tuple is a decomposition of an integer  $n$  when  $k$  occurs  $k_1$  times and  $k - 1$  occurs  $k_2$  times and  $k_1 \cdot k + k_2 \cdot (k - 1) = n$ . The number of such tuples is equal to the binomial coefficient  $\binom{k_1+k_2}{k_1}$ . We determine analogously the number of different paths between other pairs of vertices.  $\square$

Using Theorems 14 and 12 we can prove the following.

**Theorem 15.** *Let  $k \geq 2$  be integer. Then*

$$\begin{aligned}
 Fd^{(1)}(k, n) &= \sum_{i=0}^{k-1} \sum_{k_1, k_2} \binom{k_1+k_2}{k_1}, \\
 & \quad k_1 \cdot k + k_2 \cdot (k-1) = n-i-1 \\
 & \quad n \geq k,
 \end{aligned}$$

$$\begin{aligned}
 Fd^{(2)}(k, n) &= \sum_{i=k-2}^{k-1} \sum_{k_1, k_2} \binom{k_1+k_2}{k_1}, \\
 & \quad k_1 \cdot k + k_2 \cdot (k-1) = n-i-1 \\
 & \quad n \geq k,
 \end{aligned}$$

$$\begin{aligned}
 Fd^{(3)}(k, n) &= \sum_{k_1, k_2} \binom{k_1+k_2}{k_1} \\
 & \quad k_1 \cdot k + k_2 \cdot (k-1) = n-1-2(k-1) \\
 & + 3 \sum_{k_1, k_2} \binom{k_1+k_2}{k_1} \\
 & \quad k_1 \cdot k + k_2 \cdot (k-1) = n-1-(k-1) \\
 & + 4 \sum_{i=2}^{k-2} \sum_{k_1, k_2} \binom{k_1+k_2}{k_1} \\
 & \quad k_1 \cdot k + k_2 \cdot (k-1) = n-i-(k-1) \\
 & + \sum_{k_1, k_2} \binom{k_1+k_2}{k_1}, \\
 & \quad k_1 \cdot k + k_2 \cdot (k-1) = n-2(k-1) \\
 & \quad n \geq 2k - 1.
 \end{aligned}$$

(34)

Tables 1, 2, 3, and 4 present first words of four types of distance Fibonacci numbers  $Fd^{(1)}(k, n)$ ,  $Fd^{(2)}(k, n)$ ,  $Fd^{(3)}(k, n)$ , and  $Fd^{(4)}(k, n)$ .
