This paper investigates the adaptive stabilization problem for a class of stochastic nonholonomic systems with strong drifts. By using input-state-scaling technique, backstepping recursive approach, and a parameter separation technique, we design an adaptive state feedback controller. Based on the switching strategy to eliminate the phenomenon of uncontrollability, the proposed controller can guarantee that the states of closed-loop system are global bounded in probability.

1. Introduction

The nonholonomic systems cannot be stabilized by stationary continuous state feedback, although it is controllable, due to Brockett's theorem [1]. So the well-developed smooth nonlinear control theory and the method cannot be directly used in these systems. Many researchers have studied the control and stabilization of nonholonomic systems in the nonlinear control field and obtained some success [2–6]. It should be mentioned that many literatures consider the asymptotic stabilization of nonholonomic systems; the exponential convergence is also an important topic theme, which is demanded in many practical applications. However, the exponential regulation problem, particularly the systems with parameterization, has received less attention. Recently, [3] firstly introduced a class of nonholonomic systems with strong nonlinear uncertainties and obtained global exponential regulation. References [4, 5] studied a class of nonholonomic systems with output feedback control. Reference [6] combined the idea of combined input-state-scaling and backstepping technology, achieving the asymptotic stabilization for nonholonomic systems with nonlinear parameterization.

It is well known that when the backstepping designs were firstly introduced, the stochastic nonlinear control had obtained a breakthrough [7]. Based on quartic Lyapunov

functions, the asymptotical stabilization control in the large of the open-loop system was discussed in [8]. Further research was developed by the recent work [9–16]. [17–19] studied a class of nonholonomic systems with stochastic unknown covariance disturbance. Since stochastic signals are very prevalent in practical engineering, the study of nonholonomic systems with stochastic disturbances is very significant. So, there exists a natural problem that is how to design an adaptive exponential stabilization for a class of nonholonomic systems with stochastic drift and diffusion terms. Inspired by these papers, we will study the exponential regulation problem with nonlinear parameterization for a class of stochastic nonholonomic systems. We use the input-state-scaling, the backstepping technique, and the switching scheme to design a dynamic state-feedback controller with $\sum^T \sum \neq I$; the closed-loop system is globally exponentially regulated to zero in probability.

This paper is organized as follows. In Section 2, we give the mathematical preliminaries. In Section 3, we construct the new controller and offer the main result. In the last section, we present the conclusions.

2. Problem Statement and Preliminaries

In this paper, we consider a class of stochastic nonholonomic systems as follows:

$$\begin{aligned}
dx_0 &= d_0(t) u_0 dt + f_0(t, x_0) dt \\
dx_i &= d_i(t) x_{i+1} u_0 dt + f_i(t, x_0, \bar{x}_i) dt + \varphi_i(\bar{x}_i) \sum (t) d\omega, \\
&\quad i = 1, \dots, n-1, \\
dx_n &= d_n(t) u_1 dt + f_n(t, x_0, x) dt + \varphi_n(\bar{x}) \sum (t) d\omega,
\end{aligned} \tag{1}$$

where $x_0 \in R$ and $x = [x_1, \dots, x_n]^T \in R^n$ are the system states and $u_0 \in R$ and $u_1 \in R$ are the control inputs, respectively. $\bar{x}_i = [x_1, x_2, \dots, x_i]^T \in R^i$, ($i = 1, 2, \dots, n$), and $\bar{x}_n = x$; $\omega \in R^r$ is an r -dimensional standard Wiener process defined on the complete probability space (Ω, F, P) with Ω being a sample space, F being a filtration, and P being measure. The drift and diffusion terms $f_i(\cdot)$, $\varphi_i(\cdot)$ are assumed to be smooth, vanishing at the origin $(x_1, x_2, \dots, x_i) = (0, 0, \dots, 0)$; $\sum(t) : R_+ \rightarrow R^{r \times r}$ is the Borel bounded measurable functions and is nonnegative definite for each $t \geq 0$. $d_i(t)$ are disturbed virtual control coefficients, where $i = 0, 1 \dots n$.

Next we introduce several technical lemmas which will play an important role in our later control design.

Consider the following stochastic nonlinear system:

$$dx = f(x, t) dt + g(x, t) d\omega, \quad x(0) = x_0 \in R^n, \tag{2}$$

where $x \in R^n$ is the state of system (2), the Borel measurable functions: $f : R^{n+1} \rightarrow R^n$ and $g : R^{n+1} \rightarrow R^{n \times r}$ are assumed to be C^1 in their arguments, and $\omega \in R^r$ is an r -dimensional standard Wiener process defined on the complete probability space (Ω, F, P) .

Definition 1 (see [8]). Given any $V(x, t) \in C^{1,2}$, for stochastic nonlinear system (2), the differential operator L is defined as follows:

$$LV(x, t) = \frac{\partial V}{\partial t} + \frac{\partial V}{\partial x} f + \frac{1}{2} \text{tr} \left(g^T \frac{\partial^2 V}{\partial x^2} g \right), \tag{3}$$

where $C^{1,2}(R^n \times R_+; R_+)$ denotes all nonnegative functions $V(x, t)$ on $R^n \times R_+$, which are C^1 in t and C^2 in x , and for simplicity, the smooth function $f(\cdot)$ is denoted by f .

Lemma 2 (see [8]). Let x and y be real variables. Then, for any positive integers m, n , and any real number $\varepsilon > 0$, the following inequality holds:

$$\begin{aligned}
\alpha(\cdot) x^m y^n &\leq \varepsilon |x|^{m+n} + \frac{n}{m+n} \left(\frac{m+n}{m} \right)^{-m/n} \\
&\quad \times \alpha(\cdot)^{(m+n)/n} \varepsilon^{-m/n} |y|^{m+n}.
\end{aligned} \tag{4}$$

Lemma 3 (see [7]). Considering the stochastic nonlinear system (2), if there exist a $C^{1,2}$ function $V(x, t)$, K_∞ class functions α and $\bar{\alpha}$, constant \bar{c} , and a nonnegative functions $W(x, t)$ such that

$$\underline{\alpha}(|x|) \leq V(x) \leq \bar{\alpha}(|x|), \quad LV(x) \leq -W(x, t) + \bar{c}, \tag{5}$$

then for each $x_0 \in R^n$. (1) For (2), there exists an almost surely unique solution on $[0, \infty]$. (2) When $\bar{c} = 0$, $f(0, t) = 0$, $g(0, t) = 0$, and $W(x, t) = W(x)$ is continuous, the equilibrium $x = 0$ is globally stable in probability, and the solution $x(t)$ satisfies $P\{\lim_{t \rightarrow \infty} W(x(t)) = 0\} = 1$. (3) For any given $\varepsilon > 0$, there exist a class KL function $\beta_c(\cdot, \cdot)$ and K function $\gamma(\cdot)$ such that $P\{|x(t)| < \beta_c(|x_0|, t) + \gamma(c)\} \geq 1 - \varepsilon$ for any $t \geq 0$, $x_0 \in R^n \setminus \{0\}$.

Lemma 4 (see [20]). For any real-valued continuous function $f(x, y)$, $x \in R^m$, $y \in R^n$, there exist smooth scalar-value functions $a(x) \geq 0$, $b(y) \geq 0$, $c(x) > 1$, and $d(y) \geq 1$, such that $|f(x, y)| \leq a(x) + b(y)$, and $|f(x, y)| \leq c(x)d(y)$.

3. Controller Design and Analysis

The purpose of this paper is to construct a smooth state-feedback control law such that the solution process of system (1) is bounded in probability. For clarity, the case that $x_0(t_0) \neq 0$ is firstly considered. Then, the case where the initial $x_0(t_0) = 0$ is dealt with later. The triangular structure of system (1) suggests that we should design the control inputs u_0 and u_1 in two separate stages.

To design the controller for system (1), the following assumptions are needed.

Assumption 5. For $0 \leq i \leq n$, there are some positive constants λ_{i1} and λ_{i2} that satisfy the inequality $\lambda_{i1} \leq d_i(t) \leq \lambda_{i2}$.

Assumption 6. For $f_0(t, x_0)$, there exists a nonnegative smooth function $\gamma_0(t, x_0)$, such that $|f_0(t, x_0)| \leq |x_0| \gamma_0(t, x_0)$.

For each $f_i(t, x_0, \bar{x}_i)$, $\varphi_i(\bar{x}_i)$, there exist nonnegative smooth functions $\gamma_i(t, x_0, \bar{x}_i)$ and $\rho_i(\bar{x}_i)$, such that $|f_i(t, x_0, \bar{x}_i)| \leq (\sum_{k=1}^i |x_k|) \gamma_i(t, x_0, \bar{x}_i)$, $|\varphi_i(\bar{x}_i)| \leq (\sum_{k=1}^i |x_k|) \rho_i(\bar{x}_i)$.

3.1. Designing u_0 for x_0 -Subsystem. For x_0 -subsystem, the control u_0 can be chosen as

$$u_0 = -\lambda_0 x_0, \tag{6}$$

where $\lambda_0 = (k_0 + \gamma_0)/\lambda_{01}$ and k_0 is a positive design parameter.

Consider the Lyapunov function candidate $V_0 = x_0^2/2$. From (6) and Assumptions 5 and 6, we have

$$\begin{aligned}
LV_0 &= x_0 (d_0 u_0 + f_0(t, x_0)) \\
&\leq d_0 u_0 x_0 + x_0^2 \gamma_0 \leq -k_0 x_0^2 = -2k_0 V_0.
\end{aligned} \tag{7}$$

So, we obtain the first result of this paper.

Theorem 7. The x_0 -subsystem, under the control law (6) with an appropriate choice of the parameters k_0 , λ_{01} , λ_{02} , is globally exponentially stable.

Proof. Clearly, from (7), $LV_0 \leq 0$, which implies that $|x_0(t)| \leq |x_0(t_0)| e^{-k_0(t-t_0)}$. Therefore, x_0 is globally exponentially convergent. Consequently, x_0 can be zero only at $t = t_0$, when

$x(t_0) = 0$ or $t = \infty$. It is concluded that x_0 does not cross zero for all $t \in (t_0, \infty)$ provided that $x(t_0) \neq 0$. \square

Remark 8. If $x(t_0) \neq 0$, u_0 exists and does not cross zero for all $t \in (t_0, \infty)$ independent of the x -subsystem from (6).

3.2. Backstepping Design for u_1 . From the above analysis, the x_0 -state in (1) can be globally exponentially regulated to zero as $t \rightarrow \infty$, obviously. In this subsection, we consider the control law u_1 for the x -subsystem by using backstepping technique. To design a state-feedback controller, one first introduces the following discontinuous input-state-scaling transformation:

$$\eta_i = \frac{e^{\alpha t} x_i}{u_0^{n-i}}, \quad i = 1, \dots, n, \quad u = e^{\alpha t} u_1. \quad (8)$$

Under the new x -coordinates, x -subsystems is transformed into

$$\begin{aligned} d\eta_i &= d_i \eta_{i+1} dt + \bar{f}_i dt + \phi_i^T \sum_{t=0}^T (t) d\omega, \quad i = 1, \dots, n-1, \\ d\eta_n &= d_n u dt + \bar{f}_n dt + \phi_n^T \sum_{t=0}^T (t) d\omega, \end{aligned} \quad (9)$$

where

$$\begin{aligned} \bar{f}_i &= \alpha \eta_i + \frac{e^{\alpha t} f_i}{u_0^{n-i}} - \frac{(n-i) \eta_i}{u_0} \frac{\partial u_0}{\partial x_0} (d_0 u_0 + f_0), \\ \phi_i &= \frac{e^{\alpha t} \phi_i}{u_0^{n-i}}. \end{aligned} \quad (10)$$

In order to obtain the estimations for the nonlinear functions \bar{f}_i and ϕ_i , the following Lemma can be derived by Assumption 6.

Lemma 9. For $i = 1, 2, \dots, n$, there exist nonnegative smooth functions $\bar{\gamma}_i(\cdot)$, $\bar{\rho}_i(\cdot)$, such that

$$|\bar{f}_i| \leq \left(\sum_{k=1}^i |\eta_k| \right) \bar{\gamma}_i(x_0, \bar{x}_i), \quad (11)$$

$$|\phi_i| \leq \left(\sum_{k=1}^i |\eta_k| \right) \bar{\rho}_i(\bar{x}_i). \quad (12)$$

Proof. We only prove (11). The proof of (12) is similar to that of (11). In view of (6), (8), (10) and Assumption 6, one obtains

$$\begin{aligned} |\bar{f}_i| &= \left| \alpha \eta_i + \frac{e^{\alpha t} f_i}{u_0^{n-i}} - \frac{(n-i) \eta_i}{u_0} \frac{\partial u_0}{\partial x_0} (d_0 x_0 + f_0) \right| \\ &\leq |\alpha \eta_i| + \left(\sum_{k=1}^i \frac{e^{\alpha t} |x_k|}{u_0^{n-k}} |u_0^{i-k}| \right) \gamma_i \\ &\quad + (n-i) (\lambda_0 \lambda_{02} + \gamma_0) |\eta_i| \end{aligned}$$

$$\begin{aligned} &\leq |\alpha| |\eta_i| + \left(\sum_{k=1}^i |\eta_k| \lambda_0^{i-k} |x_0^{i-k}| \right) \gamma_i \\ &\quad + (n-i) (\lambda_0 \lambda_{02} + \gamma_0) |\eta_i| \\ &\leq \left(\sum_{k=1}^i |\eta_k| \right) (|\alpha| + |\lambda_0^{i-k}| |x_0^{i-k}| \gamma_i + (n-i) (\lambda_0 \lambda_{02} + \gamma_0)) \\ &\leq \left(\sum_{k=1}^i |\eta_k| \right) \bar{\gamma}_i(x_0, \bar{x}_i), \end{aligned} \quad (13)$$

where $\bar{\gamma}_i(x_0, \bar{x}_i) \geq |\alpha| + |\lambda_0^{i-k}| |x_0^{i-k}| \gamma_i + (n-i) (\lambda_0 \lambda_{02} + \gamma_0)$.

To design a state-feedback controller, one introduces the coordinate transformation

$$z_1 = \eta_1, \quad (14)$$

$$z_i = \eta_i - \alpha_i(\bar{z}_{i-1}), \quad i = 1, 2, \dots, n,$$

where $\alpha_2, \dots, \alpha_n$ are smooth virtual control laws and will be designed later and $\alpha_1 = 0$. $\hat{\theta}$ denotes the estimate of θ , where

$$\theta = \sup_{t \geq 0} \left\{ \max \left\{ \left\| \sum_{t=0}^T (t) \sum_{t=0}^T (t) \right\|^2, \left\| \sum_{t=0}^T (t) \sum_{t=0}^T (t) \right\|^{4/3}, \left\| \sum_{t=0}^T (t) \sum_{t=0}^T (t) \right\| \right\} \right\}. \quad (15)$$

Then using (9), (10), (14) and Itô differentiation rule, one has

$$\begin{aligned} dz_i &= d(\eta_i - \alpha_i) \\ &= \left(d_i \eta_{i+1} + F_i(\bar{z}_i, x_0) - \frac{\partial \alpha_i}{\partial \theta} \dot{\theta} \right) dt + G_i^T(\bar{z}_i) \sum_{t=0}^T (t) d\omega \\ &\quad - \frac{1}{2} \sum_{k,m=1}^{i-1} \frac{\partial^2 \alpha_i}{\partial z_k \partial z_m} \phi_k^T(\bar{z}_k) \sum_{t=0}^T (t) \sum_{t=0}^T (t) \phi_m(\bar{z}_m) dt, \end{aligned} \quad (16)$$

where $\eta_{n+1} = u$, $F_i(\bar{z}_i, x_0) = \bar{f}_i + \sum_{k=1}^{i-1} (\partial \alpha_i / \partial z_k) (d_k \eta_{k+1} + \bar{f}_k)$, and $G_i(\bar{z}_i, x_0) = \phi_i + \sum_{k=1}^{i-1} (\partial \alpha_i / \partial z_k) \phi_k$, where $i = 1, 2, \dots, n$. Using Lemmas 2, 4, and 9 and (14), we easily obtain the following lemma. \square

Lemma 10. For $1 \leq i \leq n$, there exist nonnegative smooth functions $\gamma_{i1}(\bar{z}_i, x_0)$, $p_{i1}(\bar{z}_i)$, and $\bar{p}_i(\bar{z}_i)$, such that

$$\begin{aligned} |F_i| &\leq \left(\sum_{k=1}^i |z_k| \right) \gamma_{i1}(\bar{z}_i, x_0), \\ |G_i| &\leq \left(\sum_{k=1}^i |z_k| \right) p_{i1}(\bar{z}_i), \\ |\Phi_i| &\leq \left(\sum_{k=1}^i |z_k| \right) \bar{p}_i(\bar{z}_i). \end{aligned} \quad (17)$$

The proof of Lemma 10 is similar to that of Lemma 9, so we omitted it.

We now give the design process of the controller.

Step 1. Consider the first Lyapunov function $V_1(z_1, \hat{\theta}) = (1/4)z_1^4 + (1/2)(\hat{\theta} - \theta)^2$. By (14), (15), and (16), we have

$$LV_1 = z_1^3(d_1\eta_2 + F_1) + \frac{3}{2}z_1^2 \text{Tr} \left(G_1^T \sum (t) \sum (t) G_1 \right) + (\hat{\theta} - \theta) \dot{\hat{\theta}}. \quad (18)$$

Using Lemma 10 and Lemma 4, we have

$$\begin{aligned} |z_1^3 F_1| &\leq z_1^4 \gamma_{11}(z_1, x_0) \\ \left| \frac{3}{2} z_1^2 \text{Tr} \left(G_1^T \sum (t) \sum (t) G_1 \right) \right| &\leq z_1^4 p_{11}^2(z_1, x_0) \theta. \end{aligned} \quad (19)$$

Substituting (19) into (18) and using (14), we have

$$\begin{aligned} LV_1 &\leq d_1 z_1^3(\eta_2 - \alpha_2) + d_1 z_1^3 \alpha_2 + z_1^4 p_{11}^2(z_1, x_0) \theta \\ &\quad + z_1^4 \gamma_{11}(z_1, x_0) + (\hat{\theta} - \theta) \dot{\hat{\theta}} \\ &\leq d_1 z_1^3 z_2 + d_1 z_1^3 \alpha_2 + z_1^4 p_{11}^2(z_1, x_0) \theta \\ &\quad + z_1^4 \gamma_{11}(z_1, x_0) + (\hat{\theta} - \theta) \dot{\hat{\theta}}, \end{aligned} \quad (20)$$

where $\alpha_2 = -z_1 \beta_1 = -z_1((c_1 + \gamma_{11} + p_{11}^2 \hat{\theta})/\lambda_{11})$. Substituting α_2 into (20), we have

$$LV_1 \leq d_1 z_1^3 z_2 - c_1 z_1^4 + (\hat{\theta} - \theta) (\dot{\hat{\theta}} - \tau_1), \quad (21)$$

where $\tau_1 = z_1^4 p_{11}^2$.

Step i. ($2 \leq i \leq n$). Assume that at step $i - 1$, there exists a smooth state-feedback virtual control $\alpha_i = -z_{i-1} \beta_{i-1}(\bar{z}_{i-1}, \hat{\theta}) = -z_{i-1}((c_{i-1} + \hat{\theta} \sqrt{1 + (\psi_{i-12} + \psi_{i-13})^2} + b_{i-1} + \psi_{i-11} + \psi_{i-14})/\lambda_{i-11})$, such that

$$\begin{aligned} LV_{i-1} &\leq -\sum_{j=1}^{i-2} (c_j - \varepsilon_j - e_j) z_j^4 - c_{i-1} z_{i-1}^4 + d_{i-1} z_{i-1}^3 z_i \\ &\quad + \left(\hat{\theta} - \theta - \sum_{k=2}^{i-1} z_k^3 \frac{\partial \alpha_k}{\partial \hat{\theta}} \right) (\dot{\hat{\theta}} - \tau_{i-1}), \end{aligned} \quad (22)$$

where $V_{i-1} = \sum_{j=1}^{i-1} (1/4)z_j^4 + (1/2)(\hat{\theta} - \theta)^2$, $\tau_{i-1} = \tau_1 + \sum_{k=2}^{i-1} z_k^4 (\psi_{i-12} + \psi_{i-13})$, and $\varepsilon_j = \sum_{k=1}^j (\varepsilon_{k1} + \varepsilon_{k2} + \varepsilon_{k3} + \varepsilon_{k4})$, where $j = 1, \dots, n$.

Then, define the i th Lyapunov candidate function $V_i(\bar{z}_i, \hat{\theta}) = V_{i-1} + (1/4)z_i^4$. From (16) and (22), it follows that

$$\begin{aligned} LV_i &\leq -\sum_{j=1}^{i-2} (c_j - \varepsilon_j - e_j) z_j^4 - c_{i-1} z_{i-1}^4 + d_{i-1} z_{i-1}^3 z_i \\ &\quad + z_i^3 \left(d_i \eta_{i+1} + F_i(\bar{z}_i, x_0) - \frac{\partial \alpha_i}{\partial \hat{\theta}} \dot{\hat{\theta}} \right. \\ &\quad \left. - \frac{1}{2} \sum_{k,m=1}^{i-1} \frac{\partial^2 \alpha_i}{\partial z_k \partial z_m} \phi_k^T(\bar{z}_k) \sum (t) \sum (t) \phi_m(\bar{z}_m) \right) \\ &\quad + \frac{3}{2} z_i^2 \text{Tr} \left(G_i^T(\bar{z}_i) \sum (t) \sum (t) G_i(\bar{z}_i) \right) \\ &\quad + \left(\hat{\theta} - \theta - \sum_{k=2}^{i-1} z_k^3 \frac{\partial \alpha_k}{\partial \hat{\theta}} \right) (\dot{\hat{\theta}} - \tau_{i-1}). \end{aligned} \quad (23)$$

Using Lemmas 9 and 4, there are always known nonnegative smooth functions $\psi_{i1}(\bar{z}_i)$, $\psi_{i2}(\bar{z}_i)$, $\psi_{i3}(\bar{z}_i)$, $\psi_{i4}(\bar{z}_i)$ and constant $\varepsilon_i > 0$, $\varepsilon_{ij} > 0$, where $i = 1, \dots, n$ and $j = 1, 2, 3, 4$.

Consider

$$\begin{aligned} z_i^3 F_i &\leq |z_i^3| \left(\sum_{k=1}^{i-1} |z_k| \right) \gamma_{i1}(\bar{z}_i, x_0) \\ &\leq \gamma_{i1} z_i^4 + \sum_{k=1}^{i-1} \left(\varepsilon_{k1} z_k^4 + \frac{3}{4} (4\varepsilon_{k1})^{-1/3} \gamma_{i1}^{4/3} z_i^4 \right) \\ &\leq \sum_{k=1}^{i-1} \varepsilon_{k1} z_k^4 + \psi_{i1} z_i^4, \end{aligned} \quad (24)$$

where $\psi_{i1} \geq \gamma_{i1} + \sum_{k=1}^{i-1} (3/4)(4\varepsilon_{k1})^{-1/3} \gamma_{i1}^{4/3}$.

$$\begin{aligned} &-\frac{1}{2} z_i^3 \sum_{k,m=1}^{i-1} \frac{\partial^2 \alpha_i}{\partial z_k \partial z_m} \phi_k^T \sum (t) \sum (t) \phi_m \\ &\leq \frac{1}{2} z_i^3 \sum_{k,m=1}^{i-1} \left| \frac{\partial^2 \alpha_i}{\partial z_k \partial z_m} \right| \left(\sum_{j=1}^k |z_j| \right) \bar{p}_k(\bar{z}_k) \\ &\quad \times \left(\sum_{j=1}^m |z_j| \right) \bar{p}_m(\bar{z}_m) \left| \sum (t) \sum (t) \right| \\ &\leq z_i^3 \left(\sum_{k=1}^{i-1} z_k^2 \right) \bar{p}_i(\bar{z}_i) \left| \sum (t) \sum (t) \right| \\ &\leq z_i^4 \psi_{i2}(\bar{z}_i) \theta + \sum_{k=1}^{i-1} \varepsilon_{k2} z_k^4, \end{aligned} \quad (25)$$

where $\psi_{i2} \geq \sum_{k=1}^{i-1} (3/4)(4\varepsilon_{k2})^{-1/3} (\bar{p}_i(\bar{z}_i))^{3/4}$.

$$\begin{aligned} &\frac{3}{2} z_i^2 \text{Tr} \left(G_i^T \sum (t) \sum (t) G_i \right) \\ &\leq \frac{3}{2} z_i^2 p_{i2}^2(\bar{z}_i) \left(\sum_{k=1}^i |z_k| \right)^2 \left| \sum (t) \sum (t) \right| \end{aligned}$$

$$\begin{aligned}
& \leq \frac{3}{2} z_i^2 p_{i2}^2 (\bar{z}_i) \left(\sum_{k=1}^i z_k^2 \right) \left| \sum^T (t) \sum (t) \right| \\
& \leq \frac{3}{2} z_i^4 p_{i2}^2 (\bar{z}_i) \theta + \sum_{k=1}^{i-1} \varepsilon_{k3} z_k^4 + \sum_{k=1}^{i-1} \frac{1}{4\varepsilon_{k3}} \left(\frac{3}{2} i p_{i2}^2 \right)^2 z_i^4 \theta \\
& \leq \sum_{k=1}^{i-1} \varepsilon_{k3} z_k^4 + \psi_{i3} z_i^4 \theta,
\end{aligned} \tag{26}$$

where $\psi_{i3} \geq (3/2) i p_{i2}^2 + \sum_{k=1}^{i-1} (1/4\varepsilon_{k3}) ((3/2) i p_{i2}^2)^2$.

$$\begin{aligned}
d_{i-1} z_{i-1}^3 z_i & \leq \lambda_{i-12} |z_{i-1}^3 z_i| \\
& \leq e_{i-1} z_{i-1}^4 + \frac{1}{4} \left(\frac{4}{3} e_{i-1} \right)^{-3} z_i^4 \lambda_{i2}^4 \\
& \leq e_{i-1} z_{i-1}^4 + b_i z_i^4,
\end{aligned} \tag{27}$$

where $b_i \geq (1/4) ((4/3) e_{i-1})^{-3} \lambda_{i2}^4$, $\tau_{i-1} = z_1^4 p_{11}^2 + \sum_{k=2}^{i-1} z_k^4 (\psi_{k2} + \psi_{k3})$, and $\tau_i = \tau_{i-1} + (\psi_{i2} + \psi_{i3}) z_i^4$.

$$\begin{aligned}
& -z_i^3 \frac{\partial \alpha_i}{\partial \hat{\theta}} \tau_i \\
& \leq z_i^3 \left| \frac{\partial \alpha_i}{\partial \hat{\theta}} \right| (\tau_{i-1} + z_i^4 (\psi_{i2} + \psi_{i3})) \\
& \leq z_i^4 \sqrt{1 + \left(z_i^3 \frac{\partial \alpha_i}{\partial \hat{\theta}} \right)^2} (\psi_{i2} + \psi_{i3}) \\
& + z_i^3 \left| \frac{\partial \alpha_i}{\partial \hat{\theta}} \right| \left(z_1^4 p_{11}^2 + \sum_{k=2}^{i-1} z_k^4 (\psi_{k2} + \psi_{k3}) \right) \\
& + \frac{3}{4} (4)^{-1/3} \left(\left| \frac{\partial \alpha_i}{\partial \hat{\theta}} \right| z_1^3 p_{11}^2 \right)^{4/3} \varepsilon_{i4}^{-1/3} z_i^4 \\
& \leq \varepsilon_{i4} z_1^4 + \frac{3}{4} (4)^{-1/3} \sqrt{1 + \left(\frac{\partial \alpha_i}{\partial \hat{\theta}} z_1^3 p_{11}^2 \right)^2} \varepsilon_{i4}^{-1/3} z_i^4 \\
& + \sum_{k=2}^{i-1} \varepsilon_{k4} z_k^4 \\
& + \sum_{k=2}^{i-1} \frac{3}{4} (4)^{-1/3} \sqrt{1 + \left(\frac{\partial \alpha_i}{\partial \hat{\theta}} z_k^3 (\psi_{k2} + \psi_{k3}) \right)^2} \varepsilon_{k4}^{-1/3} z_i^4 \\
& \leq \sum_{k=1}^{i-1} \varepsilon_{k4} z_k^4 + \psi_{i4} z_i^4,
\end{aligned} \tag{28}$$

where $\psi_{i4} \geq (3/4) (4\varepsilon_{i4})^{-1/3} \sqrt{1 + ((\partial \alpha_i / \partial \hat{\theta}) z_1^3 p_{11}^2)^2}^{4/3} + \sum_{k=2}^{i-1} (3/4) (4\varepsilon_{k4})^{-1/3} \sqrt{1 + ((\partial \alpha_i / \partial \hat{\theta}) z_k^3 (\psi_{k2} + \psi_{k3}))^2}^{4/3}$.

$$\begin{aligned}
\alpha_{i+1} (\bar{z}_i, \hat{\theta}) & = -z_i \beta_i (\bar{z}_i, \hat{\theta}), \\
\beta_i (\bar{z}_i, \hat{\theta}) & = \frac{c_i + \psi_{i1} + \psi_{i4} + b_i + \sqrt{1 + (\psi_{i2} + \psi_{i3})^2 \hat{\theta}}}{\lambda_{i1}},
\end{aligned} \tag{29}$$

where $c_i > 0$ is a design parameter to be chosen.

With the aid of (24)–(29) and (14), (23) can be simplified as

$$\begin{aligned}
LV_i & \leq -\sum_{j=1}^{i-1} (c_j - \varepsilon_j - e_j) z_j^4 - c_i z_i^4 \\
& + d_i z_i^3 z_{i+1} + \left(\hat{\theta} - \theta - \sum_{k=2}^i \frac{\partial \alpha_k}{\partial \hat{\theta}} z_k^3 \right) (\hat{\theta} - \tau_i).
\end{aligned} \tag{30}$$

Finally, when $i = n$, $z_{n+1} = u$ is the actual control. By choosing the actual control law and the adaptive law,

$$\begin{aligned}
u (\bar{z}_n, \hat{\theta}) & = -z_n \beta_n (\bar{z}_n, \hat{\theta}), \\
\dot{\hat{\theta}} & = \tau_n = z_1^4 p_{11}^2 + \sum_{k=2}^n z_k^4 (\psi_{k2} + \psi_{k3}), \\
\beta_n (\bar{z}_n, \hat{\theta}) & = \frac{c_n + b_n + \psi_{n1} + \psi_{n4} + \sqrt{1 + (\psi_{n2} + \psi_{n3})^2 \hat{\theta}}}{\lambda_{n1}}, \\
u_1 & = e^{-\alpha t} u,
\end{aligned} \tag{31}$$

where $c_n > 0$ is a design parameter to be chosen and ψ_{ni} , $i = 1, \dots, 4$ are smooth functions; we get

$$LV_n \leq -\sum_{j=1}^n (c_j - \varepsilon_j - e_j) z_j^4, \tag{32}$$

where $V_n(z, \hat{\theta}) = \sum_{k=1}^n (1/4) z_k^4 + (1/2) (\hat{\theta} - \theta)^2$, $z = (z_1, \dots, z_n)$. We have finished the controller design procedure for $x_0(t_0) \neq 0$ and the parameter identification. Without loss of generality, we can assume that $t_0 \neq 0$.

3.3. Switching Control and Main Result. In the preceding subsection, we have given controller design for $x_0 \neq 0$. Now, we discuss how to choose the control laws u_0 and u_1 when $x_0 = 0$. We choose u_0 as $u_0 = -\lambda_0 x_0 + u_0^*$, $u_0^* > 0$. And choose the Lyapunov function $V_0 = (1/2) x_0^2$. Its time derivative is given by $LV_0 = -\lambda_0 x_0^2 + u_0^*$, which leads to the bounds of x_0 . During the time period $[0, t_s)$, using $u_0 = -\lambda_0 x_0 + u_0^*$, new control law u can be obtained by the control procedure described above to the original x -subsystem in (1). Then, we can conclude that the x -state of (1) cannot be blown up during the time period $[0, t_s)$. Since at $x(t_s) \neq 0$, we can switch the control inputs u_0 and u to (6) and (31), respectively.

Now, we state the main results as follows.

Theorem 11. Under Assumption 5, if the proposed adaptive controller (31) together with the above switching control strategy is used in (1), then for any initial condition $(x_0, x, \hat{\theta}) \in R^n$,

the closed-loop system has an almost surely unique solution on $[0, \infty)$, the solution process is bounded in probability, and $P\{\lim_{t \rightarrow \infty} \hat{\theta}(t) \text{ exists and is finite}\} = 1$.

Proof. According to the above analysis, it suffices to prove in the case $x_0(0) \neq 0$. Since we have already proven that x_0 can be globally exponentially convergent to zero in probability in Section 3.1, we only need prove that $x(t)$ is convergent to zero in probability also. In this case, we choose the Lyapunov function $V = V_n$, and $c_i > \varepsilon_i + e_i$; from (32) and Lemma 3, we know that the closed-loop system has an almost surely unique solution on $[0, \infty)$, and the solution process is bounded in probability. \square

4. Conclusions

This paper investigates the globally exponential stabilization problem for a class of stochastic nonholonomic systems in chained form. To deal with the nonlinear parametrization problem, a parameter separation technique is introduced. With the help of backstepping technique, a smooth adaptive controller is constructed which ensures that the closed-loop system is globally asymptotically stable in probability. A further work is how to design the output-feedback tracking control for more high-order stochastic nonholonomic systems.
