## The gestural misinformation effect: skewing eyewitness testimony through gesture

### Abstract

The susceptibility of eyewitnesses to verbal suggestion has been well-documented, though little attention has been paid to the role of nonverbal communication in misinformation. Three experiments are reported; in each, participants watched footage of a crime scene before being questioned about what they had observed. In Experiments 1 and 2, an on-screen interviewer accompanied identically-worded questions either with gestures that conveyed accurate information about the scene or that conveyed false, misleading information. The misleading gestures significantly influenced recall and participants' responses were consistent with the gestured information. In Experiment 3, a live interview was conducted and the gestural misinformation effect was found to be robust; participants were influenced by misleading gestures performed by the interviewer during questioning. These findings provide compelling evidence for the gestural misinformation effect, whereby subtle hand gestures can implant information and distort the testimony of eyewitnesses. The practical and legal implications of these findings are discussed.

## The gestural misinformation effect: skewing eyewitness testimony through gesture

The susceptibility of eyewitnesses' memory has been a key issue in forensic research, and a wealth of studies have highlighted eyewitnesses' sensitivity to misleading post-event information. Most notably, studies have shown that a witness's responses can be influenced by manipulation of a question's wording (Loftus, 1975; Loftus & Zanni, 1975). Witnesses can be directed to give a particular response when presented with a biased answer set (Loftus, 1975; Tversky & Kahneman, 1974) or a descriptive verb which insinuates details of an event (Harris, 1973; Loftus & Palmer, 1974). The *misinformation effect* (Loftus & Hoffman, 1989) proposed that witnesses are sensitive to post-event information which can alter their perception of the original event: Based on this theory, witnesses' memories of events are constructed from information that is available to them, and the introduction of inaccurate post-event information during questioning becomes integrated with the original encoded memory. As a result of this process, witnesses can form an inaccurate representation of what they observed and many studies cite cases where false post-event information has skewed eyewitness testimony as a result of this process (see Loftus, 2005, for a review).

Misinformation is not limited to biased questioning, but can also be presented through visual, pictorial cues, such as doctored photographs and advertisements. Braun, Ellis, & Loftus (2002) found that when participants were presented with visual evidence that contradicted details of their holiday experience they were found to alter their reported memory to coincide with this new information. Similarly, participants have also been found to report historic events inaccurately when presented with visual evidence that contradicts the original event (Sacchi, Agnoli, & Loftus, 2007). As with verbal information, post-event visual details can become integrated into the eyewitnesses' memory and lead them to believe that this is what was originally observed. Whilst the susceptibility of eyewitness memory to these manipulations is well researched, less attention has been paid to how other, nonverbal cues can influence eyewitnesses. Far less is known about how a witness's memory can be skewed by post-event information conveyed nonverbally, in particular; through hand gestures. Thus,

we propose the gestural misinformation effect and investigate how information conveyed in gestures acts as a form of misinformation and influences an eyewitness's responses.

Gestures are ubiquitous in human communication. They can expand on information that is communicated verbally (Langton, O'Malley, & Bruce, 1996; Sacchi, et al., 2007), add clarity to speech (Goldin-Meadow, 1993; Kendon, 1980) and make communication between a speaker and listener more effective (Beattie & Shovelton, 1999; Graham & Argyle, 1975). Gestures can also communicate information that is difficult to articulate in speech (Church & Goldin-Meadow, 1986), such as complex shapes or ambiguous line drawings (Goldin-Meadow, 1999; Graham & Argyle, 1975). Listeners may also depend on gestures for information, particularly in situations when the verbal source is ambiguous (Thompson & Massaro, 1986) or inaudible (Rogers, 1978). Whilst gestures can build on information in speech, they can also provide critical semantic details that are absent from speech. Kendon (1980) describes a speaker talking about a 'large cake' and making a large circular movement of the index finger, portraying its round shape. When asked about the shape of the cake, listeners remember it as round even though this was not mentioned in speech.

Gestures play a critical role in the way information is communicated. Kelly, Barr, Church, & Lynch (1999) showed how additional semantic information about a story could be gleaned from gesture and reported by listeners afterwards: Participants watched a video of a woman saying "*my brother went to the gym*" in one of two conditions; 'speech' (no gesture) or 'speech and gesture' (the woman accompanied her speech with a 'shooting a basketball' gesture). Participants in the latter condition reported that her brother had gone to play basketball, even though this was not stated in speech. In addition, some participants falsely recalled the woman as saying "*my brother went to play basketball*". This demonstrates that gestures can convey semantic content and can also influence the comprehension and memory of pragmatic information.

Further support for this notion comes from Cassel, McNeill & McCullough (1999). In their study, participants watched a video narration of a 'Sylvester & Tweetie' cartoon showing a narrator accompanying his speech with either supplementary (matched) hand gestures or contradictory

(mismatched) hand gestures. For instance, for the phrase "*Granny whacks Sylvester*", the narrator either performed a (matched) 'slapping' gesture or a (mismatched) 'punching' gesture. The authors reported a marked difference in how the two groups retold the story. The mismatched gesture group reported more of the incorrect details conveyed than the matched gesture group (40% and 5% respectively). To further this, the authors report one participant as saying "*...and granny like punches him or something*". Together, these studies suggest that gestures form an integral part of communication with information conveyed in gesture becoming integrated into the listeners' memory representation.

Sensitivity to misleading information in gestures has been demonstrated in children. In the study by Broaders & Goldin-Meadow (2010), thirty nine children were asked open-ended questions, accompanied by the interviewer gesturing specific information (e.g., asking "*what else did he do?*" while gesturing '*playing a whistle*'). They found that conveying misleading information in this way altered the children's representation of the event and led them to give inaccurate information that was consistent with the gesture. Children however are known to be more susceptible to suggestions and memory encoding errors than adults (Bruck & Ceci, 1999; Poole & Lindsay, 2002) therefore it is an open question as to whether adults' testimony would be similarly influenced. Replicating this effect in adults would lend support to the notion that gestured information can alter memory representation and subsequently skew eyewitness testimony.

In light of the substantive support for verbal misinformation, and evidence that gestures play an important role in communication, this study explores whether gestures may also act as a form of misinformation during the questioning of eyewitnesses. Three experiments examined whether participants' responses to questions about a crime scene could be manipulated by a 'police' interviewer portraying misleading information through his hand gestures. It was predicted that gestures would serve as a form of misinformation and that participants would incorporate gestured information into their testimony.

## Experiment 1

Participants first watched footage of a crime scene, followed by a questioning phase on video, where a 'police' interviewer asked participants questions about the crime. By presenting the questioning phase on video it was possible to ensure that the verbal questions were identical for all groups; careful video editing allowed for manipulation of the interviewer's gestures whilst keeping the verbal questions constant. During questioning, participants saw the interviewer accompany the questions with a gesture that either conveyed accurate information about the scene (an 'accurate' gesture) or inaccurate information (a 'misleading' gesture). To establish what responses would be elicited in the absence of any visual information a control group was included, comprising participants who only heard the audio of the interviewer's questions but did not see the questioner.

Therefore, all groups heard identical verbal questions and any differences in their testimonies could be attributed to non-verbal factors. It was predicted that their responses would concur with the information conveyed to them in the interviewer's gesture.

## Method

### *Design*

A between subjects design was used, with three conditions: 'accurate gesture', 'misleading gesture' and control (no gesture). The dependent variable was the response participants gave to the critical question.

### *Participants*

Sixty six undergraduate psychology students (13 male, 53 female) from the University of Hertfordshire ranging in age from 18-48 ( $M = 21.24$ ,  $SD = 4.51$ ) were allocated randomly to one of the three groups ( $N = 22$  for each). Participants were awarded course credit for taking part.

## *Materials*

The stimuli presented to participants included a CCTV-style video of a confrontation between two individuals in a dark alleyway. The video had no sound and lasted approximately 45 seconds.

For the questioning phase of the experiment, a video was constructed where an actor played the role of a police interviewer. The video was filmed at the University of Hertfordshire's Observation Laboratory and showed the interviewer sitting at a desk with a folder to resemble a police interview scenario. During filming, one camera was positioned in front of the interviewer, whilst a second was positioned over his shoulder to capture his hand gestures. In order that all participants heard the same verbal questions, the filming of the question was only recorded once and the accompanying gestures were recorded separately afterwards.

The first critical question was "*you may have noticed some jewellery worn by the victim, please write down what jewellery you think he was wearing*" and was spoken directly to camera. For the two corresponding 'over-shoulder' videos, the interviewer either gestured to a finger on his opposing hand (to depict a "ring") or grasped his wrist (to depict a "watch"). These two 'over-shoulder' shots of the gesture were each edited into the video sequence in full screen (during the word "*jewellery*") to produce two versions of the video for the two experimental conditions. The video in each condition thus comprised of the same footage of the interviewer talking directly to camera, but with the camera angle changing briefly to show either an accurate gesture of a "ring", or a misleading gesture of a "watch". (In the crime scene the man wore a ring, but no watch.) Therefore, both groups heard exactly the same question but each group saw it accompanied by a different gesture.

In addition to the critical question, three distracter questions (how tall was the man? / how old was the man? / what colour jacket was he was wearing?) and an introductory video (showing the interviewer writing at a desk) were filmed. All videos were directed in the same manner, with occasional camera angle changes so to not make participants suspicious of the camera angle changes in the critical question videos. A series of black screen videos were presented to participants in the control group as they listened to the audio questions.

## *Procedure*

All participants watched the same crime scene video followed by the questioning phase. The presentation of the videos for the questioning phase varied by condition: Those in the 'accurate' condition saw the interviewer performing the accurate (ring) gesture for the critical question, and those in the 'misleading' condition saw the misleading (watch) gesture. Participants in the control group saw no video (only a black screen) and heard only the audio from the interviewer's questions. An introductory video of the 'police' interviewer was shown accompanied by a voiceover instructing participants to watch the crime scene carefully so they could answer questions about it afterwards. The questioning phase followed with two distracter questions, the critical question then the distracter question, each separated by a 12-second segment of black screen to enable participants to write down their answer to the question. Controls saw a black screen throughout this phase of the experiment.

## **Results**

Participants wrote down their responses to the interviewer's critical question concerning the man's jewellery. 'Ring' and 'watch' were the target responses for each of the "ring" and "watch" categories, though other items of jewellery worn on the wrist (such as a bracelet) were also counted as valid responses to the watch gesture. Other items of jewellery including 'earring', 'chain' or 'necklace' were logged as "other" responses. If participants failed to give an answer in the accurate ( $N = 2$ ), misleading ( $N = 4$ ) and control ( $N = 6$ ) groups their data was excluded from the analysis.

More correct (ring) responses were given by participants that saw the 'accurate' (ring) gesture (95%,  $N = 19$ ) compared to those who saw the 'misleading' (watch) (67%,  $N = 12$ ) gesture and control (no gesture) (63%,  $N = 10$ ) group. Subsequently, more incorrect responses of 'watch' were given by those who saw the misleading watch gesture (30%,  $N = 6$ ) compared to the accurate (5%,  $N = 1$ ) or control (19%,  $N = 3$ ) groups. The association between condition (gesture: accurate, misleading, and control) and response (ring, watch, other) was examined in a chi-square test and was found to be significant,

$\chi^2(4, N = 54) = 12.10, p = .016$ . The incorrect responses revealed that no participants in the accurate (ring) condition answered 'watch', but 'watch' made up all ( $N = 6$ ) of the incorrect responses in the misleading (watch) group and 50% ( $N = 3$ ) of the incorrect responses from controls. The responses of the control group appeared to be more varied as the remainder of their answers were made up of more miscellaneous ("other") responses ('earring' and necklace). Thus, the gesture performed to participants appeared to affect the responses they gave.

## Discussion

The results of experiment 1 suggest that participants' responses were largely consistent with the information conveyed to them in gesture. Participants' memory of some of the detail in the scene appeared to have been aided by the accurate gesture and distorted by the false information from the misleading gesture. These results are consistent with previous research which found that verbal questioning can distort a participant's existing memory of events (Loftus & Hoffman, 1989; Loftus & Palmer, 1974). Noteworthy is how some participants that gave the incorrect response of 'watch' (or bracelet) in the misleading condition elaborated their report with additional details of the item, such as it being 'gold' or 'silver', despite it being absent from the scene. (In comparison, no participants in the control that gave the same incorrect answer elaborated on their responses.) These results provide preliminary support for the gestural misinformation effect and suggest that nonverbal, as well as verbal, information can influence what an eyewitness remembers.

While this experiment revealed that gestures could lead participants to both a correct and incorrect response, the questioning made it clear that jewellery was present in the scene. Rather than suggesting the presence of jewellery, it is possible that the gesture may only have altered perceptions of what jewellery this was. An outstanding question is whether gestures can suggest the presence of objects that were absent from the crime scene. This is explored in the next study which involves suggesting to participants, via gesture, the presence of an object that was in fact absent from the scene they witnessed.

## Experiment 2

Research into the misinformation effect provides evidence that leading questions can not only distort memories (Loftus & Hoffman, 1989; Loftus & Palmer, 1974) but can also prompt the creation of entirely new memories (Garry, Manning, Loftus, & Sherman, 1996; Loftus & Pickrell, 1995), even if they would have been impossible to observe (Braun, et al., 2002). Experiment 1 provided support that gestures could distort a memory, though it is not possible to conclude at this stage that gestures can also *implant* memories. Experiment 2 addressed this by exploring whether gestures could suggest the presence of objects that did not appear in the video participants witnessed. Two groups were exposed to misleading gestures during questioning, with each gesture suggesting the presence of a different absent feature. For this experiment, a new stimulus video of an office theft was used, and three critical questions were developed; concerning the man's physical characteristics. These questions concerned the man's facial features and whether he was wearing any jewellery. A question regarding jewellery was also used. However, as the man wore no jewellery in this scene, both the "ring" and "watch" gestures were misleading. Therefore, this experiment explored whether multiple misleading gestures could implant a memory of an object into the participant's representation of the scene. Further methodological changes included the introduction of multiple choice answer sets to ensure a cleaner data set. A short distracter task was also introduced between the stimulus and recall videos of the experiment to help reduce memory trace of the video.

## Method

### *Design*

A between subjects design with participants randomly allocated to three conditions; gesture group 1, gesture group 2 and control/no gestures.) The dependent variable was the responses participants gave to each of the critical questions.

## *Participants*

The 72 participants were adults (20 males, 52 females), ranging in age from 18-81 ( $M = 30.31$ ,  $SD = 17.93$ ) (24 in each condition). Participants were predominantly psychology undergraduates who were awarded participation credit for taking part.

## *Materials*

A 30-second stimulus video was created. It depicted a thief entering an office, placing a stolen item in his jacket pocket and then exiting the room. The clip had no sound.

As in experiment 1, a series of interviewer videos were prepared for the questioning part of the experiment. As before, participants were asked "*was the man wearing any [jewellery]?*" with a full-screen over-shoulder camera cutaway edited in the sequence of the interviewer gesturing either a 'ring' (gesture group 1) or 'watch' (gesture group 2) gesture on the word "jewellery". As the man was not wearing any jewellery, both gestures in this experiment were misleading.

Videos for another two critical questions were prepared. In these videos, the interviewer performed the critical gesture while asking the question directly to camera without any 'over-shoulder' cutaways. Therefore, two versions of these critical questions were recorded separately to correspond to each gesture condition. The 'additional clothing' critical question asked "*did you notice [anything else] he was wearing?*" with misleading gestures "gloves" (grasping opposing hand) and "hat" (touching head) occurring on the words "*anything else*" for gesture groups 1 and 2 respectively. The 'facial features' critical question asked "*you got a glimpse of his [face] in the video. Do you remember any distinguishing features?*" with the interviewer performing either a "beard" (stroking chin) or "glasses" (touching nose bridge) gesture on the word "*face*" for gesture groups 1 and 2 respectively. Three distracter questions were included, (how tall was the man? / how old was the man? / what did he take as he left?) which also featured naturalistic gestures. The audio in the blank (black screen) video for the control group was selected from one of these videos at random for each critical question.

Answer booklets with multiple choice answers were provided. The responses in all answer sets included the 'answer' portrayed through the gesture in both conditions, as well as a further two distracter answers and an "other" (none) response.

### *Procedure*

Participants watched the crime scene stimulus video and completed a short distracter task (lasting approximately 5 minutes) before progressing to the recall phase of the experiment. The gestures participants saw was dependent on condition. Those in gesture group 1 saw the "ring", "gloves" and "beard" gestures, and those in gesture group 2 saw the "watch", "hat", and "glasses" gestures for the critical 'jewellery', 'additional clothing' and 'facial features' questions respectively. Participants in the control group saw a black screen video and heard only the audio from the questions.

The questions were presented in a designated order (two distracter questions, critical question, distracter, critical, distracter, critical). Each question was separated by a 12-second segment of black screen to enable participants time to select an answer from a list of multiple choices for all questions. Participants were instructed to choose one response from those in the answer booklet, and to select 'other' if they believed the response was not listed.

### Results

Participants gave an answer to the three critical questions asked by the questioner (concerning the man's jewellery, additional clothing and facial features) by choosing one item from a given answer set. Thus, all responses were categorical. Any positive response was considered to be incorrect (the man was wearing no jewellery, no additional clothing, and had none of the distinguishing facial features listed).

While there were no correct responses, the majority of responses given by the control group consisted of the "other" (or none) response (53%). In contrast, the majority of responses for the two misleading gesture groups were made up of other incorrect responses (68% and 54% in the two gesture groups respectively) including both target and miscellaneous responses. A summary of the target responses are provided in figures 1, 2 and 3.

*Insert figures 1a, 1b and 1c about here.*

The "ring" and "watch" gestures generated more of each response in their respective gesture conditions (60%,  $N = 6$  and 100%,  $N = 10$  respectively). Similarly, the "gloves" and "hat" gestures prompted more of those answers in each condition (75%,  $N = 6$  and 56%,  $N = 5$ ). For the 'facial features' question, the "beard" gesture did result in a greater number of 'beard' responses (93%,  $N = 14$ ), though remained a frequent answer across both the 'glasses' (90%,  $N = 9$ ) and control conditions (71%,  $N = 5$ ). The "glasses" gestures did not appear to exert an influence (10%,  $N = 1$ ).

The effect of the gestures were first analysed by comparing the frequency of the responses consistent with the misleading gesture with the frequency with which the same response occurred in the absence of the gesture (control condition). Overall, of the participants that saw a misleading gesture, 29% gave the response conveyed by it. Comparatively, 15% of participants gave the response when they did not see the gesture. This data was submitted to a 2x2 chi-square analysis testing an association between gesture (saw gesture / not) and response (gave target response / not) and retrieved a significant effect;  $\chi^2 (1, N = 282) = 7.90, p = .005$ . Thus, participants' responses were associated with the gesture performed to them.

To further this analysis, a Mann-Whitney U test was performed. As participants in the experimental groups saw three misleading gestures, the data were scored according to how many target responses

they gave (ranging from 0 to 3). The test revealed that those in gesture group 1 gave significantly more target responses than controls,  $U = 165.5$ ,  $n_1 = 24$ ,  $n_2 = 24$ ,  $p = .006$ . Similarly, those in gesture group 2 gave more target responses than controls, though this did not reach significance;  $U = 229.0$ ,  $n_1 = 24$ ,  $n_2 = 24$ ,  $p = .170$ .

## Discussion

The results of experiment 2 provide further support that hand gestures may act as a form of misinformation and skew eyewitness' responses. Across the three critical questions, participants' responses concurred with the information that was conveyed to them through gesture. While some responses remained popular across all conditions ('gloves' and 'watch'), and may reflect guesses, it still remains that more of that response in those responses arose in their respective conditions. Although the 'glasses' gesture had comparatively little effect (and in fact prompted more 'beard' responses) this result could be explained by the gesture's ambiguity. For this gesture the interviewer simply touched the bridge of his nose, a movement that may have conveyed little information.

Building on the findings from experiment 1, these results further suggest that gestures may influence participants to give a particular response. In this experiment, the 'ring' gesture conveyed misleading information, and generated a higher number of 'ring' responses. Noteworthy also is how three of the participants that gave the 'ring' response also reported the man wearing 'gloves' after seeing the gloves gesture; incompatible answers that would have been impossible to observe.

While these findings provide further insight into gestural misinformation, some considerations about the methodology should be made. Participants in experiments 1 and 2 were questioned over video and were not able to interact with the interviewer. While this ensured the questioning was rigorously controlled, it could be argued that ecological validity was compromised. Previous research indicates a decrease in communicative value when a speaker's gestures are presented through video rather than live (Holler, Shovelton, & Beattie, 2009) and visual attention to speaker's gestures differs between

video and live conversations (Gullberg & Holmqvist, 2002, 2006). As the form of gesture presentation varies, so may the effects of gestural misinformation. To assess how effective misleading gestures can be in a real interview situation, the methodology was developed to accommodate these discussion points.

### Experiment 3

Experiments 1 and 2 found that gestures could distort and create participants' memories when presented through video. These results provide considerable support for the existence of gestural misinformation. In light of these observations, it is important to investigate whether the effects of gestural misinformation are replicated in a live, face-to-face, interview. Testing gestural misinformation in a live interview is an important progression; the cognitive interview technique widely used today is conducted live and designed to ease social interaction between the witness and interviewer (Fisher & Geiselman, 1992). In addition, gestures performed by speakers live are more likely to draw attention from the listener (Gullberg & Holmqvist, 2002, 2006) and be processed for information intuitively (Gullberg & Kita, 2009). Thus, exploring gestural misinformation in a more naturalistic, live interview, would provide considerably more insight into whether gestures can skew eyewitness testimony under questioning.

In experiment 3, participants were questioned on the stimulus video by a interviewer face-to-face who again performed misleading gestures while asking his questions. Participants were able to interact with the interviewer and responded freely to his questions after providing a statement on what they had witnessed. This method ensured participants were more engaged with the interviewer and gesture presentation was more natural. Thus, this experiment provided an environment more representative of a police interview.

As in experiment 2, the interviewer performed one of either two sets of misleading gestures (or no gestures, for the control condition). Further methodological improvements were made in this

experiment. Firstly, gestures that confounded with another (i.e. "ring" and "gloves") were arranged so they did not appear in the same condition and one gesture ("glasses") was modified so it conveyed information less ambiguously. In addition, another critical question (concerning which pocket the man put an item in) was introduced.

## Method

### *Design*

As in experiment 2, a between subjects design allocated participants randomly to three groups; the first were presented with one set of misleading gestures (gesture group 1), the second with another set of misleading gestures (gesture group 2) and a third, control group, saw no gestures. The dependent variable was the responses that participants gave to each of the critical questions in the interview. All dependent variables were measured as categorical responses.

### *Participants*

A sample of 90 participants (16 male, 74 female) were recruited opportunistically for the experiment, ranging in age from 18-32 ( $M = 19.75$ ,  $SD = 2.37$ ). The majority of participants were undergraduate or postgraduate psychology students from the University of Hertfordshire who were awarded participation credit for taking part.

### *Materials*

The same stimulus video (showing a theft in an office) as in experiment 2 was used here. A funnel debrief questionnaire was also prepared for this experiment and asked "*did you feel influenced by the in the interviewer in any way?*" and "*which of his hand gestures do you remember seeing?*"

### *Procedure*

Participants watched the stimulus video and completed a short distracter task before proceeding through to the 'interview room' containing a table with 2 chairs facing each other, placed approximately 1 metre apart. When seated, the participants completed a short distracter task and wrote a statement of what they saw in the video before the interview commenced.

The interviewer followed a transcript to ask the questions. During the interview for the experimental conditions, he performed the critical gestures whilst summarising the events of the video. For instance, for the facial features question, the interviewer explained "*at one point in the video the man turned around and you got a glimpse of his face*" with the critical "*beard*" or "*glasses*" gesture occurring on the phrase "*his face*". The interviewer then asked "*were there any distinguishing features you think he may have had?*"

As before, distracter questions were prepared (how old was the man? / what colour was his jacket? / which drawer did he take the item from?) and were sandwiched between the critical gesture and question. The interview continued to follow this pattern of 'critical gesture, distracter question, critical question' for the 'jewellery' and 'additional clothing' questions. A further critical question was "*which jacket pocket do you think he put the item in?*" following a critical gesture of either "left inside pocket" (gesture group 1) or "right outside pocket" (gesture group 2).

The interviewer performed the same gestures as in experiment 2, though the "glasses" gesture was changed to a gesture of two imaginary circles around his eyes. The interviewer performed other, non-critical gestures when discussing the events of the video so to not draw attention exclusively to the critical gestures. The interviewer also avoided deictic expressions (i.e. "*[like this]*") and did not fixate any of his gestures. Care was taken to avoid deviating from the transcript if participants interrupted or answered prematurely

In the control group, the interviewer asked the same standardised questions but did not perform any accompanying gestures. This method allowed for a more naturalistic control group in contrast to the black screen videos used in experiments 1 and 2.

The interviewer avoided asking leading questions. For instance, participants were asked "*did you notice any additional clothing?*" as opposed to "*what additional clothing was he wearing?*" If a participant claimed they did not know, they were asked if they were sure before moving into the next question. After questioning, the interviewer clarified the answers with the participant during a summary of the interview to ensure they were happy with the responses given.

## Results

Participants answered freely to the interviewer's questions by giving their responses verbally, which were then written down by the interviewer. In this experiment, four critical questions were asked (concerning the man's jewellery, what other clothing he was wearing and what facial features he had). The fourth critical question asked which jacket pocket he put an item in. Responses that were congruent with the interviewer's gesture were counted as target responses. As before, 'bracelet' was also accepted as a target response for "watch" (for the jewellery question) and 'facial hair' or 'stubble' was accepted as a target response for "beard" (for the facial features question). Figures 4, 5 and 6 summarise the responses given by gesture groups.

*Insert figures 2a, 2b and 2c about here*

More of the responses given in the control group correctly identified no target responses (86%) compared to those in the two misleading gesture conditions (72% and 77% respectively). The "ring", "watch", "gloves" and "beard" gestures prompted more of each response in their respective conditions (56%,  $N = 5$ ; 100%,  $N = 10$ ; 67%,  $N = 2$ , 100%,  $N = 10$ ) while the "glasses" and "hat" gestures did not yield the majority of responses in their respective conditions (50%,  $N = 2$ ; 29%,  $N = 2$ ). To analyse the effect of the gestures, the frequency of target responses and the frequency with which the same

response occurred without a gesture (control group) were compared for the three critical questions together. Participants that saw a misleading gesture were more likely to give the target response (17%), compared to those who did not see the gesture (7%). A significant association was found between response and gesture condition,  $\chi^2(1, N = 77) = 4.19, p = .041$ . Thus, participants that saw the interviewer accompanying the question with a hand gesture were more likely to give the response conveyed by this gesture.

A further Mann-Whitney U test considered the number of target responses participants gave between those that saw misleading gestures and controls. Participants could have given either 0, 1, 2 or 3 target responses to the previous three critical questions. The test revealed that those in gesture group 1 gave significantly more of the target responses than controls;  $U = 307, n_1 = 30, n_2 = 30, p = .007$ , as did those in gesture group 2;  $U = 340, n_1 = 30, n_2 = 30, p = .038$ .

A further question was asked concerning which jacket pocket the intruder put an item in. For this question there was a positive answer (the intruder did put the item in a pocket, though which pocket was unclear) Participants chose either his left or right pocket, and then his inside or outside pocket. Some participants did not provide a full answer in gesture group 1 ( $N = 5$ ), gesture group 2 ( $N = 3$ ) or the control group ( $N = 4$ ) and some participants ( $N = 3$ , all in gesture group 2) gave the pocket side but not the pocket type. Participants that saw the interviewer performing a "left inside" gesture were more likely to claim the item was put in his left inside pocket (48%,  $N = 12$ ) compared to those in the other gesture (15%,  $N = 4$ ) or control (23%,  $N = 6$ ) groups. In contrast, those that saw him perform the "right outside" gesture were more likely to give the 'right outside' response (59%,  $N = 16$ ) compared to those in the alternate (24%,  $N = 6$ ) but not control group (61%,  $N = 16$ ). Thus, as the responses of the control group were closely matched to those who saw the "right outside" gesture, the "left inside" gesture directed participants away from their natural tendency. The data were submitted to a 3x4 chi-square testing an association between condition ("left inside" / "right outside" / no gesture) and response (left inside / left outside / right inside / right outside) and retrieved a significant effect,  $\chi^2(6, N = 78) = 13.47, p = .036$ . To investigate this further, another 3x2 chi-square collapsed the data by the

right / left responses and the inside / outside responses independently. An effect was present for just the right / left responses,  $\chi^2 (2, N = 81) = 6.17, p=.046$ , and the inside / outside responses,  $\chi^2 (2, N = 78) = 12.27, p=.002$ .

## Discussion

While experiments 1 and 2 established that gestures can affect participants' responses through video, this experiment revealed that gestures can also affect responses when questioned live, in a face-to-face interview. As participants were free to interact with the interviewer and gave free responses to his questions, this experiment provides a more ecologically valid representation of a police interview and provides more compelling evidence that gestures can affect eyewitness testimony.

Across experiments 2 and 3, participants that saw a misleading gesture were significantly more likely to give a target response than those who did not. The “glasses” and “hat” gestures were the only gestures not to contribute to this effect. An explanation for this could be that these gestures appeared too ambiguous to communicate their respective information. The lower proportions of positive responses from participants in general may also have prevented these differences from being observed. While research highlights that gestures may be more communicative live than through video (Holler, et al., 2009), the proportion of participants who gave a target response live was lower (17%) than through video in experiment 2 (29%). An alternative explanation for this is the methodological differences between the experiments, namely, the use of a forced-choice questionnaire in experiment 2, and further experiments could address this issue.

## General Discussion

Previous research has shown that the manipulation of verbal information can skew the memory of eyewitnesses and have an effect on the responses they give (Harris, 1973; Loftus, 1975; Loftus &

Palmer, 1974). This study demonstrates that witnesses can also be misled by information that is conveyed through hand gestures. This study builds on research that gestures can suggest additional semantic information to listeners (Cassell, et al., 1999; Kelly, et al., 1999) and that such information can affect eyewitness testimony not only in children (Broaders & Goldin-Meadow, 2010) but also in adults. In experiment 1, when the interviewer's question was accompanied by a consistent 'accurate' gesture participants were more likely to produce an accurate report. When his question was accompanied by a gesture that was inconsistent with the facts, they were more likely to report inaccurate information. Experiment 2 confirmed that two separate misleading gestures were able to manipulate responses independently under the same conditions. Since the information reported by participants in these experiments could not have been based on their observations and was largely consistent with the interviewer's gestures (while his speech remained identical across all conditions) there appears to be strong support that the interviewer's gestures influenced the participants' responses. In experiment 3, these results were replicated in a more ecologically valid interview scenario. In addition, this experiment revealed that while participants reported feeling influenced, and could identify misleading gestures when they were performed to them, they were still susceptible to information conveyed through gesture. In light of these findings, this study provides evidence for a gestural misinformation effect and indicates that misleading post-event information can mislead eyewitnesses not only through speech, as previous research has shown, but also through gesture.

This study furthers understanding of the communicative potential of gesture by demonstrating that semantic information from gestures can not only be integrated with speech, but is also salient enough to produce a robust misinformation effect. However, this study has more far-reaching implications and shows that while hand gestures can have many positive effects (such as increasing the efficiency of communication), there may also be negative effects. This study highlights that participants can recall false information presented only through gesture and that such an effect could have an impact in the questioning of eyewitnesses. The *cognitive interview* has proved an effective way of reducing inaccurate eyewitness testimony by removing biased questioning (Fisher & Geiselman, 1992; Memon, Zaragoza, Clifford, & Kidd, 2010; Wells, Memon, & Penrod, 2006) though gestural misinformation

remains as a possible form of influence. Audio recording interviews enables identification of when a witness has been misled by the wording of a question. However, to ensure any nonverbal persuasion is detected, it would be important for initial interviews with witnesses to be video recorded, ensuring that the interviewer is fully visible on the recording as well as the witness. Without this, any answers given as a consequence of a misleading gesture are likely to occur 'off the radar'.

Gesture influence may also be more covert and occur incidentally. Gestures typically differ from speech in representation and often serve a different role in communication (McNeill, 1996). While speech conveys information in a “segmented, combinatorial” format, gestures convey information in a “global, mimetic” style (Goldin-Meadow, McNeill, & Singleton, 1996). Gestures also compliment speech fluently, whereas speech is far less fluent, and full of errors and hesitations (Cassel, 2000). A key feature of gestures is their ability to communicate visual details that are not articulated in speech (Cassell, et al., 1999; Goldin-Meadow, 1999; Graham & Argyle, 1975; Kendon, 1980). Thus, gestures may suggest the imagery of a scene and cause witnesses to confuse the semantic details conveyed to them through gesture with those actually witnessed. While gestures are not readily noticed by participants, and occur as 'background elements' in conversation (Henderson & Hollingworth, 1999), they are a powerful tool in communication.

This has important implications, as gestural information that misleads witnesses may be less overt than speech, and may be more difficult to identify. An interviewer may not necessarily intend to influence a witness, but may inadvertently ‘suggest’ information via their hand gestures. Gesture production is spontaneous and unplanned (Krauss, 1998; McNeill, 1996) and may be produced for intrapersonal benefits, such as lexical retrieval, without communicative intent (Rauscher, Krauss, & Chen, 1996). Despite this, listeners can still extract meaning from them (Krauss, Chen, & Gottesman, 2000). The 'semantic specificity hypothesis', for example, shows that gestures for 'praxic' objects (those which use the hands to function) are more ubiquitous than those for non-praxic objects (Pine, Gurney, & Fletcher, 2010). Therefore, while speech can be controlled, the production of gestures is

often automatic and, as such, a speaker has less awareness of them and of the information they may convey.

This observation raises questions into the process through which gestural influence occurs. One possibility is that participants responded intuitively to the interviewer's suggestions and accepted these suggestions due to demand characteristics. Witnesses have been shown to accept suggestions from interviewers intuitively, particularly those perceived to have greater knowledge and expertise (Skagerberg & Wright, 2009; Smith & Ellsworth, 1987). However, information conveyed through gesture may not be processed as overtly as information conveyed through speech, and an alternative explanation is that participants gleaned information from gesture outside of their awareness. Gestures are rarely fixated upon by the listener during a conversation (Gullberg & Holmqvist, 1999, 2006), though information can still be extracted from them: Gullberg & Kita (2009) studied the relationship between gesture fixations and information uptake across a series of studies, but found no evidence of an association between the two, suggesting that gestures communicate information to addressees covertly. While studies that garner explicit measures of retrospective gesture recognition are sparse, it is noteworthy that some have drawn attention to the inability of participants to identify gesture as the source of information. For instance, participants in Kelly, et al's (1999) study heard the speaker say "*my brother went to the gym*" accompanied by a 'shooting a basketball' gesture later misremembered her as saying "*my brother went to play basketball*". Therefore a gesture can communicate critical information to listeners without the listener being aware of the source of that information and participants can be misled by gestures outside of their awareness.

Certain properties of gestures may also increase the likeliness of them skewing eyewitnesses' responses. False memory creation is facilitated by imagery ability (Dobson & Markham, 1993; Drivdahl & Zaragoza, 2001) and imagined events can become confused with real memories (Goff & Roediger, 1998; Thomas, Bulevich, & Loftus, 2003; Wright, Loftus, & Hall, 2001). If gestures provide listeners with visual, semantic information that is not articulated in speech (Cassell, et al., 1999; Goldin-Meadow, 1999; Kelly, et al., 1999; Kendon, 1980) this extra perceptual detail offered

by gestures may facilitate the creation of false memories. In line with the theory that memories are 'reconstructed' rather than 'replayed' (Loftus & Hoffman, 1989), the additional post-event information provided from gestures can also become integrated with details from the original memory and form a new representation of the witnessed event.

There are still considerations to be taken into account with this research. Participants in this study were told to "watch the video carefully", yet most witnessed events occur spontaneously without warning and usually without a determined effort being made to encode the facts. Accuracy of eyewitness memory also decreases with time (Kassin, Ellsworth, & Smith, 1989; Penrod, Loftus, & Winkler, 1982), thus a time delay may make participants more susceptible to having their fading memory representation skewed by a misleading gesture and produce an even greater effect.

In summary, this study demonstrates the potential effects of misleading hand gestures in skewing the memory and responses of eyewitnesses. It adds to the substantial and robust evidence showing that witnesses can be misled by verbal questioning. Future empirical research into eye-witness testimony should take account of the gestural misinformation effect and the power of nonverbal influence, particularly its implications for criminal and forensic proceedings.
