Can Empathy Promote Cooperation when Status and Money Matter?

Abstract

In the present study, we ask: Does empathy also support cooperative behaviors when the status (high, low) of an individual differs relative to other group members and is determined by either chance or effort? In response to this unexplored question, the present study involved a series of **four** experiments using a linear public goods game (**Experiment 1-3, 4-player, Experiment 4, 2-player**). Regardless of the way in which status was achieved (chance, effort) those with **low** status cooperated **more** compared with their **high** status counterparts. **Empathy in and of itself revealed very small overall increases in cooperative behavior**. Overall, status and monetary incentives appear to be more salient than empathy in guiding behaviors in a social dilemma task.

Keywords: status, cooperation, chance vs. effort, empathy, incentives, public goods game (PGG),

Introduction

How we come to gain our resources has been a matter of interest for many psychologists and economists, because the general speculation is that we are uniquely tuned to whether they are gained fairly or unfairly. For instance, equality of opportunity (Loury, 1981) refers to situations in which, *ceteris paribus* (all else being equal), the opportunity for gaining resources is either determined through chance factors, which all members of a group are subject to, or through effort alone. This means that the perception of fairness in the opportunities to gain resources will vary with respect to how they are gained, and there is speculation that this also influences the type of interactions between individuals of differing levels of resources. For instance, the psychological state of fairness is “the concern to be treated equally, includes the concern for how much money or resource are distributed amongst individuals (distributive fairness) and the belief that one should receive what one is due based on one’s actions (reciprocal fairness)” (Kamas & Preston, 2012, p. 538). Moreover, Yamamoto and Takimoto (2012) claim that prosocial behaviors, motivated by empathic concerns, can only exist in connection to a sense of fairness, which is determined by the way in which resources are gained and how they are distributed. The implications here being that, empathic concern may support pro-social behaviors within a social context, but these may be potentially attenuated depending on how unfairly resources are perceived to be, or actually, gained.

On this basis, the present study aims to address the following two questions: 1) To what extent are pro-social behaviors impacted in situations in which the resources gained (either through chance or effort) by one individual in the group differ? 2) To what extent does empathy promote pro-social behaviors given the way in which one individual in a group achieves their status (i.e. through chance or effort)? Thus far, prior work has examined these questions separately, and so the aim of the present study is to address both within the same experimental set up. To investigate the first question, in a pro-social decision-making task,

1
2
3 the impact on pro-social behaviors was examined when the status achieved by one individual
4 within the group, was determined experimentally by the amount of initial endowment (High
5 vs. Low), achieved either through effort or chance. To investigate the second question, given
6 the manipulation of status, empathy was experimentally induced towards other individuals in
7 a group decision-making task in order to investigate the impact on pro-social behaviors. In
8 what follows, we first provide details regarding the operationalization of the key concepts (i.e.
9 cooperation, status, empathy) that inform the manipulations we introduce in our experiments,
10 we then discuss previous work examining the relationship between status and cooperation,
11 and empathy and cooperation, and thereafter provide the theoretical foundations for the
12 specific predictions we test in our four experiments.

24 **Operationalization of Cooperation, Status, and Empathy**

25
26 **Cooperation:** Pro-social behaviors are often taken to include a broad category of acts
27 that are agreed by some significant proportion of society, or one's social group, as behaviors
28 that are generally beneficial to others (Penner, Dovidio, Piliavin, & Schroeder, 2005). In the
29 present study, consistent with others (Marcus, 1991), we treat cooperation as an example of a
30 pro-social behavior. In definitions of cooperation, an essential property is the relationships
31 between the individual's roles within a group. If cooperation is considered from the
32 perspective of an individual within a group, the definition of cooperation is *behavior that*
33 *benefits the group or collective, often at the cost of individual benefits* (Irwin, McGrimmon,
34 & Simpson, 2008). If cooperation is considered from the view of individuals performing joint
35 behaviors, then cooperation is *behaviors directed toward a goal in which the participants*
36 *gain equal rewards* (Marwell & Schmitt, 1975), and, to further qualify the mutual aspect,
37 they should also have *shared intentions* (Derlega & Grzelak, 1982; Liebal, Colombi, Rogers,
38 Warneken, & Tomasello, 2008; Warneken & Tomasello, 2007). However, as many have
39 discussed, outcomes of cooperative behaviors need not be based on altruistic motivations,

1
2
3 and so in the same vein, joint action need not be based on mutual motivations. Crucially the
4 shared goal of the cooperative endeavor is key. Thus, consolidating the different approaches
5 to conceptualizing cooperation, we propose that what is critical to cooperation is *behaviors*
6 *directed toward a shared goal in which a participant performs an action that another(s) gain*
7 *rewards from.*

8
9
10
11
12
13 **Status:** When it comes to status, in the present study we treat status as a term that
14 includes, but is not limited to, constructs such as socioeconomic status (SES), social
15 influence resource-holding potential, and social class (Kafashan, Sparks, Griskevicius, &
16 Barclay, 2014), the latter of which has been found to affect behaviors associated with social
17 engagement (Cote, 2011; Kraus & Stephens, 2012). Status here tends to reflect subjective
18 judgments about one's standing within a group (relative to others in that group), and is often
19 based on one's views about one's prestige, for which "*respect*" gained by others is the basis
20 of judged prestige as proposed by the group engagement model (Tyler & Blader, 2003).
21 Alternatively, and a concept adopted in the present study, is that status is determined more
22 explicitly by the assets that each member of the group have gained (i.e. financial wealth
23 relative to each group) (Bothner, Kim & Smith, 2012).

24
25
26
27
28
29
30
31
32
33
34
35
36
37 **Empathy:** Empathy has been defined as "the ability to recognize and understand the
38 thought process of another" (Underwood & Moore, 1982, p. 144) and "the ability to identify
39 and understand the feelings of another" (Krebs, 1975, p. 1135). Here empathy consists of two
40 components, cognitive empathy and affective empathy. Cognitive empathy is also called
41 "cold" empathy or "perspective taking" or "theory of mind", whereas affective empathy is
42 referred to as "hot" empathy (Loewenstein, 2000; Paal & Bereczkei, 2007). Empathy, in
43 general, makes it possible to understand the behaviors of family, friends or even strangers,
44 from the point of view of the emotional reasons behind their actions. Some have gone as far
45 to suggest that without empathy, it is impossible for us to interact with others appropriately

1
2
3 (Baron-Cohen, 2011). Given the multifaceted nature of empathy, some researchers have
4 attempted to consolidate the various aspect of empathy by considering eight uses of the term
5 of empathy (Batson, 2011, pp. 12-19). Looking across the various definitions of empathy,
6 and consolidating much of the social psychological literature on empathy, we propose that
7 typically empathy is an *other-oriented emotion elicited by and congruent with the perceived*
8 *welfare of someone in need*. The emotional states that are elicited can include sympathy,
9 compassion, softheartedness, tenderness, sorrow, sadness, upset, distress, concern, and grief;
10 and it involves feelings for the other rather than the self. Put more succinctly, our definition
11 treats empathy as an emotional state in which people display “empathic concern”, though this
12 could also be dispositional, in that people vary in the degree to which they display the state of
13 empathic concern.

26 **Previous work examining associations between achieved status and cooperation**

27
28 **Previous work has explored** the basis on which status is achieved and the impact that
29 it has on pro-social behaviors. Several studies have manipulated the basis on which assets are
30 gained (i.e. tokens that were then used in a cooperative game) either through chance, or
31 through effort. **For instance**, in some cases participants were randomly assigned to one of two
32 conditions in which effort (high vs. low) determined the basis on which assets (50 tokens)
33 were gained (Muehlbacher & Kirchler, 2009). Alternatively, tokens could be randomly
34 assigned to participants by the experimenter in advance to mimic acquisition of assets via
35 inheritance (Komorita, Parks, & Hulbert, 1992) or via lotteries. Equal opportunity via effort
36 was examined by assigning tokens based on performance on a specific task prior to playing a
37 cooperative game, which was designed to mimic situations in which access to greater wealth
38 is achieved by meeting performance criteria in job settings (Kroll, Cherry, & Shogren, 2007).
39 Taken together, the general pattern of findings suggests that cooperative behaviors are
40 reduced for those that achieve their status through effort (Muehlbacher & Kirchler, 2009;

1
2
3 Rockmann & Northcraft, 2008). However, thus far, there is no direct comparison of the
4 impact on cooperation, within the same task paradigm, when assets are achieved either
5 through chance or effort. Moreover, there are no direct comparisons of achieved status (i.e.
6 through chance or effort) on cooperative behaviors within a group, when status manipulations
7 impact only one of the members of the group. Thus, prior work provides vital clues regarding
8 a link between status and cooperative behaviors, but does not enable a clear understanding of
9 the degree to which status gained by either chance or effort has differential effects on levels
10 of cooperation within a group, which provides further motivation for our study.

20

21 **Previous work examining associations between empathy and cooperation**

22
23 One of the most common ways to promote cooperation is through the inducement of
24 empathy. Typically, empathy inducement methods (e.g., the presentation of stories of
25 suffering, or being instructed to perspective take) is introduced as an independent variable in
26 experimental studies in order to examine the effects of empathy on cooperation in laboratory
27 settings using variants of economic games (e.g. Public Goods Game (PGG), Prisoners
28 Dilemma). Many studies have reported that empathy induction promotes or at least maintains
29 cooperative behaviors (Allsop, Fifield, & Seiter, 2002; Batson & Moran, 1999; Cialdini et al.,
30 1987; Eimontaite, Nicolle, Schindler, & Goel, 2013; Fultz, Batson, Fortenbach, McCarthy, &
31 Varney, 1986; Oswald, 1996, 2002; Pavey, Greitemeyer, & Sparks, 2012; Rumble, Van
32 Lange, & Parks, 2010; Stürmer, Snyder, Kropp, & Siem, 2006; Xu, Kou, Zhong, 2012).
33
34 However, investigations that have since tried to replicate these studies have reported a null
35 effect of empathy induction on cooperation (LV, Proulx, Osman, 2015; Oswald, 1996;
36 Warren & Walker, 1991; Xu et al., 2012, Study 2). Other than typical cooperative laboratory
37 based tasks, alternatives such as resource allocation games that involve negotiation between
38 groups of participants, have tried to induce perspective taking (i.e. cold empathy) (Epley,
39 Caruso, & Bazerman, 2006; Gilin, Maddux, Carpenter & Galinsky, 2012) as well as empathy

4
5 as a means of promoting pro-social behaviors. As with studies using economic type games,
6
7 the findings here are also mixed. Taken together, the pattern of findings regarding the
8
9 positive impact of empathy, both hot and cold versions, on pro-social behaviors is not
10
11 reliable, particularly perspective taking manipulations. For this reason, we aim to further
12
13 investigate whether it might be the case that the empathy-cooperation link is more likely to be
14
15 strengthened in situations where resources are gained fairly (equal-resource distribution) as
16
17 compared to less fairly (unequal-resource distribution) (Yamamoto & Takimoto, 2012).
18
19

20 **Theoretical underpinnings**

21
22 As outlined earlier, one motivation of the present study is to examine the link between
23
24 the basis on which status is gained, and levels of cooperative behavior. Kafashan et al. (2014)
25
26 has proposed that the association between the two arises as a result of two different functions,
27
28 based on their bi-directional causation account for which there is considerable evidence.
29
30 Either pro-social behavior can be used to help achieve status (Willer, 2009a), or possessing
31
32 status can change the perceived costs and benefits of engaging in pro-social behavior; this
33
34 second functional role is the focus of the present study. The former suggests that collective
35
36 behaviors can be used to profit an individual's status, thus prosocial behavior functions to
37
38 achieve or maintain status, which can either be material or social rewards. For instance, in a
39
40 management context, group performance can contribute to the status of an individual that is
41
42 taking responsibility for the group (i.e. the formation of leaders) (Henrich, Chudek, & Boyd,
43
44 2015), the impact of which can be material as well as reputational.
45
46
47

48
49 With regards to the second functional association, the status of an individual can
50
51 impact the dependency of others within a group, and they behave pro-socially to maintain or
52
53 lessen the status of the individual within the group. For instance, there is considerable work
54
55 showing that when it comes to charitable donations low-status individuals are more likely to
56
57
58
59
60

1
2
3 show pro-social behavior than high status individuals (Bennett, 2012; Guinote, Cotzia,
4 Sandhu, & Siwa, 2015; Piff, Kraus, Côté, Cheng, & Keltner, 2010). One reason for this is
5 that inflated personal views of one's personal status can be used to justify the reduced levels
6 of generosity towards other group members (Hays & Blader, 2016); the costs are perceived as
7 high and the benefits are perceived as low with respect to inequality of resource allocation.
8
9 Resource-based exchange theories claim that the exchange of material resources is the
10 fundamental reason that people act cooperatively, including *interdependence theory*
11 (Joireman, Kuhlman, Van Lange, Doi, & Shelley, 2003; Kelley & Thibaut, 1978; Van Lange
12 & Gallucci, 2003). Alternatively, identity-based theories such as *group engagement model*
13 (Tyler & Blader, 2003) and *appropriateness framework* (Weber, Kopelman, & Messick, 2004)
14 claim that behaving cooperatively helps to obtain identity through group membership.
15 According to resource-based exchange theories, differences in social status affects one's
16 costs and benefits analysis with resultant changes in behavior towards others. Therefore, if
17 changes occur to a person's relative status within a group, the proclivity for cooperative
18 behavior will change due to either the change in obtained material resources, or the relative
19 identity they could potentially obtain.

24
25
26
27
28
29
30
31
32
33
34
35
36

37 Some work has looked at the extent to which these theoretical accounts are supported
38 empirically through laboratory tasks such as linear public goods game (PGG) which consists
39 of only one Nash equilibrium that everyone contribute nothing, and one Pareto efficient
40 solution that everyone contribute everything (Abele, Stasser, & Chartier, 2010). Here each of
41 four players can choose to contribute a certain amount of their endowment to a common pot
42 (i.e. an index of cooperation), which is distributed equally amongst all four players. In typical
43 versions of linear PGG each player is endowed with the same amount of tokens (homogenous
44 set up), but introducing heterogeneity via an unequal amount of tokens can serve as a proxy
45 for different levels of status (Cherry, Kroll, & Shogren, 2005). Consistent with work on status
46
47

51
52
53
54
55
56
57
58
59
60

1
2
3 and charitable donations, there is some evidence to suggest that low-status individuals (i.e.
4 those endowed with less tokens than the rest of the group) contributed more than high status
5 individuals (Bennett, 2012). Given that experimental manipulations of endowment
6 heterogeneity in PGG creates a lab-analogue of low-status and high-status, we use a similar
7 paradigm in the present study. Based on previous work assuming a functional relationship
8 such that status affects the costs and benefits of pro-social behavior, high status individual
9 will view the costs of pro-sociality as higher than low status individuals, because of their
10 perceived entitlement of their status. Thus we test the following predictions:

11
12
13
14
15
16
17
18
19
20 Prediction 1: Overall low-status individuals will show greater cooperation, as
21 evidenced through contributions to a public good, compared to high-status individuals.

22
23
24 Prediction 2: If perceived entitlement plays a role, then high status individuals will
25 feel more entitled when they achieve their status through effort than when achieved through
26 chance, and so will display lower levels of cooperation through contributions to a public good
27 compared to high-status individuals achieving their status through chance.

28
29
30
31
32
33 To the extent that individuals show any cooperative behaviors in the empirical work
34 discussed, we need to consider what the possible underlying mechanism is that promotes this
35 type of behavior. Moreover, if high status individuals typically show less cooperative
36 behaviors than low status individuals, we consider it of importance to empirically investigate
37 ways in which we can artificially promote cooperative behaviors through empathy. The
38 grounds on which we consider the potential positive impact of empathy on promoting
39 cooperation in general, as well as on those that achieve high status, comes from social
40 psychological research. Social psychological theories claim that humans display cooperative
41 behaviors through a mechanism that suggests a central role for empathy.

42
43
44
45
46
47
48
49
50
51
52 Existing resource-based exchange theories emphasize self-interested motives or
53 economic motivations as the basis on which cooperative behaviors are observed. Nonetheless,

1
2
3 economic motivations (i.e. maximizing personal wealth) do not fully explain the range of
4 possible reasons for acting cooperatively in mixed-motives dilemma games (e.g., PGG). For
5 these reasons alternative accounts have been proposed that suggest empathic concern for
6 others can motivate cooperative behaviors at a personal cost to each individual.
7
8
9

10
11 One reason for this is that it is claimed that a feature of humans that apparently sets us
12 apart from other species is our focus on others' well-being (broadly referred to as altruism)
13 (Batson, 2011). Also, we will, sometimes, at great personal cost, protest outcomes that we
14 consider unfair, whether they personally affect us or have no direct impact on our lives. The
15 association that empathy has with altruism in turn has implications for the basis on which
16 empathy promotes cooperative behaviors; relevant theories associated with this are empathy-
17 altruism hypothesis theory (Batson, 2011) and the negative-state relief hypothesis (Cialdini,
18 Kenrick, & Baumann, 1982). The former assumes that empathy will produce concern for
19 another's welfare, which motivates the individual to act pro-socially. The later argues that
20 empathy induction triggers egoistic motivations, in which individuals act pro-socially in
21 order to relieve the negative affective state - one of temporary sadness or sorrow- by
22 witnessing another person' suffering. Both theories predict that empathetic concern (either
23 through perspective taking or affective empathy) promote cooperative behavior, but diverge
24 significantly with respect to the underlying motivation (altruism or egoism). In the case of the
25 empathy-altruism hypothesis (Batson, 2011), it predicts that if we feel empathetic concern for
26 another group member, we will be altruistically motivated towards them, which is observed
27 through contributing tokens to the group pot in a PGG. Given that neither of these theoretical
28 accounts make any specific claims that could be used to generate predictions with respect to
29 status, we consider the fairness and empathy account proposed by Yamamoto and Takimoto
30 (2012). They claim that empathy promotes prosocial behaviors, whereas a sense of fairness
31 stabilizes prosocial behaviors. The two work in tandem, where empathy promotes prosocial
32
33
34
35
36
37
38
39
40
41
42
43
44
45
46
47
48

57
58
59
60

1
2
3 behaviors under a sense of fairness, and empathy is attenuated under conditions in which a
4 sense of fairness is undermined. In fact, they claim that empathy alone will not operate in
5 promoting prosocial behaviors in the absence of a sense of fairness. They also claim that the
6 basis of the complementary role between the two is driven by an evolved preference for
7 similarity to others. That is, the more similar we perceive we are to others, the more likely it
8 is that, through a sense of fairness, empathy will promote prosocial behaviors. Thus, in the
9 present study, given our empathy manipulations, we test the following predictions:
10
11
12
13
14
15
16
17

18 Prediction 3: Overall, when perspective taking inducements of empathy are present,
19 irrespective of status manipulations, there should be greater displays of cooperation through
20 contributions to a public good compared to no-empathy inducements.
21
22
23

24 Prediction 4: If a sense of fairness is used to complement empathy in supporting
25 cooperative behaviors, then under conditions in which empathy inducements are present,
26 there should be evidence of an impact of empathy on cooperation under conditions in which
27 the status of individuals is equal (i.e. fair), rather than unequal (unfair).

31
32
33

34 35 **General Methods**

36 37 38 **Overview**

39
40 In the present study four experiments were reported in which real participants were
41 exposed to a series of 10 rounds in a linear PGG while interacting with three fictional players
42 (Experiments 1-3), and another real player (Experiment 4). The assignment of participants to
43 key experimental conditions (high-status v.s low-status) in Experiment 1 was based on a
44 random draw of a colored ball picked from an occluded black box (chance-status). Thus,
45 Experiment 1 tested predictions 1, and 3. In Experiment 2 participants were assigned to status
46 conditions (high-status vs. low-status) according to their performance on a digit cancellation
47 test (effort-status), and thus tested predictions 1, 2, and 3. Experiment 3 was a pure test of the
48
49
50

52
53
54
55
56
57
58
59
60

manipulation of empathy on cooperation, in which the endowments were the same for all participants. Experiment 3 tested prediction 3 and 4. Experiment 4 was a replication and extension of Experiment 1 in which all players in the 2-player PGG were real and interacted with each other, and in which the allocation of status (low-status, equal-status) was dependent on chance (chance-status). Experiment 4 tested prediction 3 and 4.

In all four experiments the analysis of the data was the same. We first checked the effectiveness of the empathy manipulation and then conducted a mixed repeated-measures ANOVA to examine the effects of empathy and status on cooperation using proportion of contribution (PoC) in the PGG.

Experiment 1

Experiment 1 was designed to test the extent to which empathy (through perspective taking manipulations) induced cooperative behaviors in a PGG under conditions in which status (high-status, low-status) was achieved through chance.

Method

Participants

Ninety-four volunteers (58 female and 36 male) were recruited from Queen Mary University of London via emails and fliers. The mean age of the participants was 20.71 years (range from 18 to 32; $SD = 3.09$). Based on the condition they were assigned to, they were given different final payments. In the high-status condition, participants were paid between £10 and £15 (\$14.02 - \$21.02); in the low-status condition, participants were paid between £5 to £7 (\$7.01 - \$9.81).

All participants gave written informed consent prior to participation. After the experiment, they were paid an amount for their participation on the basis of the tokens gained in the PGG. In each PGG 25 tokens was equal to £1 (\$1.40), which all participants were made aware of at the start of the experiment. The Ethics Committee of the university

1
2
3 approved the study. The experiment was carried out in accordance with The Code of Ethics
4 of the World Medical Association (Declaration of Helsinki); **as with the other three**
5 **experiments.**
6
7
8
9

10 ***Design and Materials***

11
12 Experiment 1 was a 2×2 (Empathy [high-empathy, no-empathy] \times Chance-status
13 [high-status, low-status]) between-subject experimental design. The critical dependent
14 variable was participants' proportion of contributions (PoC) in each round of the PGG, which
15 comprised 10 rounds in total. Participants' contributions from round to round were assessed.
16
17 In addition, we recorded other dependent measure in a set of questions given before
18 (demographics, personal stories, hobbies) and after the main task (estimates of similarity,
19 estimates of empathy, believability of study, strategy development). The pre-questions
20 requested details on age and gender, and questions concerning participant's positive (i.e.
21 "Describe an event that has happened to you that has made you happy in the last year") and
22 negative experiences (i.e. "Describe an event that has happened to you that has made you sad
23 in the last year"), and their hobbies. Post-questions consisted of rating scales to assess
24 participants judged similarity to, and empathy towards each of the three virtual players. The
25 post-questions recorded participants' impression (similarity, empathizing) towards the three
26 other virtual players on a 9-point scale, ranged from 1 (*not at all*) to 9 (*very much*).
27
28 Participants' photos were taken at the start of the experiment using a phone camera that was
29 uploaded on screen along with the photos of the three virtual players; these steps were
30 designed to ensure that participants felt that all of the participants in the game were
31 experiencing the same procedures, and were supposedly interacting with each other live
32 online. The reasons for using virtual rather than real players was to allow for careful
33 manipulations of the range of empathy and the impact it would have on the participants'
34 behavior during the PGG. The three other virtual players' photos and profiles were made in
35

2
3 advance, and piloted. Finally, debriefing questions were presented to participants to assess
4 whether they believed that they were interacting with three other players online, and whether
5 they recognized the three other players.
6
7

8
9 The PGG was programmed and implemented via a computer using E-prime 2.0
10 software. The game was arranged such that each participant was playing with three other
11 players whose actual profiles including stories (regarding either negative events they
12 experience, or their chosen hobbies) and photos were prepared in advance; this method is
13 often referred to as “interaction deception”. In the high-empathy condition, the three other
14 players’ profiles referred to a negative event that had been experienced (Player 1 = a break up
15 with a partner, Player 2 = a car accident, Player 3 = a stolen mobile phone), which to some
16 extent can be categorized as social pain/psychological pain. In addition, participants were
17 instructed, “While you are reading this, try to imagine how the person felt about what they
18 have just described. Try to imagine how the person feels as a result (i.e. perspective taking
19 instruction), which was based on Batson & Moran’s (1999) empathy induction method. In the
20 no-empathy condition, the profiles referred to neutral events (Player 1 = swimming, Player 2
21 = ride bicycle, Player 3 = running most mornings). There were no perspective-taking
22 instructions as to how to read the profiles. Crucially, it is worth pointing out here that the
23 empathy induction methods we used are perspective taking (Batson & Moran, 1999; Epley, et
24 al, 2006; Gilin, et al, 2012), which is more typically construed as cold empathy, rather than
25 hot empathy (Loewenstein, 2000; Paal & Bereczkei, 2007). In addition, while we tried to
26 match the suffering stories with the neutral stories in terms of word length, and level of detail,
27 it is possible that the suffering stories could be construed as more socially oriented than the
28 neutral stories. In this regard, the emphasis in both suffering and neutral stories were couched
29 in terms that made salient the experiences of the individual, rather than emphasising any
30 social component of the stories in both sets.

1
2
3 The assignment of participants to each experimental condition was carried out prior to
4 the main experiment. The method by which we manipulated the high-status and low-status
5 conditions was based on the endowments of the participant in each round. This study
6 involved a status manipulation, in which half of the real participants were endowed with 30
7 tokens (high-status) and the other half were endowed with 10 tokens (low-status) on each
8 round. All the three other virtual players were given 20 tokens per round regardless of high-
9 status or low-status group. Thereafter the allocation to empathy and no-empathy conditions
10 was determined randomly. In this PGG program, the amount contributed by the three virtual
11 players was fixed across for all participants and was based on the average contributions
12 reported in Fehr and Gächter's study (2000) (taking into account the standard deviation) in
13 the partner-treatment without punishment condition. The combined total contribution of the
14 three virtual players on each round was as follows: 27, 34, 31, 24, 22, 23, 24, 18, 12 and 10.

28 29 *Procedure*

30
31 Each participant was tested individually in a soundproofed experimental cubicle
32 facing a computer monitor. After reading the information sheet and signing the consent form,
33 participants were required to pick a ball from a black box without looking inside and were
34 told the color of ball determined their assignment to an experimental condition. If they picked
35 the red ball, the participants were assigned to the high-status condition; if they picked the
36 blue ball, they were assigned to the low-status condition.

49
50
51
52
53
54
55
56
57
58
59
60
Next, the experimenter told the participant that since the experiment required them to
work with three other players online together, they were required to do some preparation. "As
we said in the information sheet, you are going to play this joint task with three other players
online. We cannot let you talk with each other, since we need to conduct this study under
controlled conditions. What we will do is exchange your profile with three other players. In
order to do that, we need to collect your picture and some personal information." Having

1
2
3 been informed that their data would be kept confidentially (i.e. only for the purposes of the
4 experiment, after which there would be no basis on which an individual participant would be
5 identifiable from the data collected), participants were asked to fill in the pre-questions, and
6
7 to take a photo with a neutral facial emotion in front of a white walled background.
8
9 Participants were then asked to wait for approximately 5 minutes and were told that the time
10
11 was needed to coordinate the other players that were taking part in the experiment; this is
12
13 where the interaction deception was involved. During this time participants were told to
14
15 carefully read the instruction for the PGG. According to the color of ball they picked, they
16
17 were given the corresponding instruction for that condition. In the high-status condition, the
18
19 instruction explained that they would be given 30 tokens per round, whereas in the low status
20
21 condition, the instructions explained that participants would be given 10 tokens per round; in
22
23 both cases, participants were made aware that the other participants would have 20 tokens per
24
25 round.
26
27
28
29
30

31 The experimenter came back to the experimental cubicle after uploading the
32
33 participants' picture to the computer running the PGG program. The experimenter asked the
34
35 participants to explain the instructions in order to demonstrate their understanding of the task.
36
37 Then the experimenter showed participants the three other players' pictures alongside their
38
39 own picture. "These are the players you are going to play with, and you will see their profile
40
41 in the program." To be more persuasive, the real participant picture was always the first
42
43 picture to be presented, and the three other face photos followed. After entering some basic
44
45 information (participants' number, gender, age), they were reminded of the instructions of the
46
47 PGG. Then they were asked to wait for the experimenter to set up the other players, and on
48
49 return, participants were instructed to press the SPACE key to get started.
50
51

52 In the PGG program, the high-empathy condition was presented with the empathy
53
54 induction procedure. They were instructed: "Next you will see profiles of the three other
55
56
57
58
59

1
2
3 participants who will work together with you. While you are reading this, try to imagine how
4
5 the person felt about what they have just described. Try to imagine how it has affected them
6
7 and how they feel as a result". In the no-empathy condition, participants were instructed:
8
9 "Next you will see the profiles of three other participants who will work together with you."
10
11 After these instructions all participants were consecutively presented with the picture and
12
13 profile of each of the three players. After seeing the profiles, participants started the PGG.
14
15 For each round when participants were required to decide on how many of their tokens to
16
17 contribute, they were presented with the pictures of the three other players. In the high-status
18
19 condition, it was from 0 to 30 tokens; whereas in the low-status condition, it was from 0 to 10
20
21 tokens. After they had made their decision, they entered their choice, and were required to
22
23 wait between 4000 to 12000 ms, randomly determined by the program. Then they were given
24
25 feedback, "Other people contributed tokens: (the sum of three other players' contributions);
26
27 Your contribution this round is: (the number of tokens they contributed); Your share of the
28
29 pot for this round: (the total number of tokens they will receive on that round); and Your
30
31 cumulative total of tokens across rounds (the total number they will receive across all
32
33 rounds)". Then the program moved to the next round. This procedure was repeated until all
34
35 10 rounds were complete. Participants were required to copy down all the values presented
36
37 on each round using a pen and form provided. The reason for this was to make sure that
38
39 participants attended to all the feedback information presented on the screen on each round.
40
41
42 On completion of the PGG, participants were then presented with the post questionnaires, and
43
44 then the debrief questions, after which they were informed of details about the study, its
45
46 purpose and the interaction deception issue.

Results

Cohen (1988) provides a benchmark to define small (.1), medium (.3) and large (.5) effects where Cohen's d is presented. Where effect sizes for partial η^2 are presented, the following broad classification is used to define small (.02), medium (.13) and large (.26) effects (Bakeman, 2005). In the analyses we presented in this and the remaining three experiments, we use these benchmarks to determine the size of the effects we report.

Empathizing Manipulation Check

For Experiment 1, an independent-samples t -test was conducted on judgments regarding the extent to which participants empathized with the experiences of the other players they were interacting with in the PGG in no-empathy ($n = 49$) and high-empathy ($n = 45$) conditions. Empathizing judgments were higher in the high-empathy conditions ($M = 4.75$, $SD = 1.44$) compared to the no-empathy conditions ($M = 3.71$, $SD = 1.96$), ($d = -.604$).

Empathy & Status manipulation

The mean PoC in each of the 10 rounds in the four conditions for Experiment 1 are shown in Figure 1; the overall mean PoC for each condition is: high-status no empathy ($M = .44$, $SD = .18$), low-status no empathy ($M = .56$, $SD = .18$), high-status empathy ($M = .49$, $SD = .18$), low-status empathy ($M = .55$, $SD = .18$).

Insert Figure 1

In all analyses of contributions made in the PGG here and in the other three experiments, we analyse the proportion of contributions made, not the absolute values. The reason for this is that the total amounts that could be contributed differ in range given our manipulations of status. That is those in the high status conditions could contribute anything between 0 and 30 tokens on each round, those in the low status conditions could contribute anything between 0 and 10 tokens on each round, and respondents (though fictitious, but

1
2
3 based on actual prior contributions reported by Fehr and Gächter's study (2000)) could
4 contribute anything between 0 and 20 tokens. Given these differences, and to make sensible
5 comparisons, the proportion of contributions of the endowment on each round were used in
6 any analyses of PGG contributions.
7
8
9

10
11 A univariate analysis was conducted with PoC in the first round as a dependent
12 variable, and empathy and chance-status as fixed-factor variables. **There was a very small**
13 **Chance-status × Empathy interaction on first round contributions ($\eta_p^2 = .001$).** There
14 was a small main effect of empathy on PoCs ($\eta_p^2 = .02$); and a small main effect of chance-
15 status on PoCs ($\eta_p^2 = .04$). Focusing on PoCs across rounds, a $10 \times 2 \times 2$ (Round [1:10]),
16 within-subject variable × (Empathy [high-empathy, no-empathy]) × (Chance-status [high-
17 status, low-status]) between-subject variables repeated-measures ANOVA was conducted.
18 **The interaction between chance-status and empathy was very small ($\eta_p^2 = .01$)** (see
19 Figure 1). Also, **there was also a very small main effect of empathy on PoCs, ($\eta_p^2 = .003$).**
20 There was a small main effect of chance-status on PoCs (see Figure 1), ($\eta_p^2 = .06$), and a
21 small main effect of round, ($\eta_p^2 = .06$), suggesting a general decrease in contributions across
22 rounds. Overall, we found that across rounds the low-status group contributed more to the
23 group pot compared to the high-status group.

40 Discussion

41
42 **The key finding in Experiment 1 supported prediction 1,** suggesting that the low-
43 status group behaved more cooperatively than the high-status group. **There was weak**
44 **support for prediction 3. That is, there were very small effects to suggest that the**
45 **inducement of empathy increased contributions in the PGG; there was some evidence to**
46 **support this when looking at first round contributions, but this was very small when**
47 **looking across rounds.**
48
49
50
51
52
53
54

55 In Experiment 1 status was determined by chance, in order to mimic situations in
56
57
58
59
60

1
2
3 wealth is determined by lotteries. However, in real life setting status can also be determined
4
5 by effort. Therefore, Experiment 2 was devised with two purposes in mind. First, the aim was
6
7 to examine the extent to which the same pattern of results would be found under a different
8
9 institution system of status acquisition, and to further examine the association between
10
11 empathy and cooperation.
12
13
14

15 Experiment 2

16
17 In all respects but one, namely the way in which status was achieved, the design and
18
19 procedure of Experiment 2 was identical to Experiment 1.
20
21

22 Method

23 *Participants*

24
25 Ninety-eight volunteers (71 females and 27 males) were recruited from Queen Mary
26
27 University of London via emails and fliers. The mean age of the participants was 21.10 years
28
29 (range from 18 to 44; $SD = 4.06$). The payments for participating were the same as
30
31 Experiment 1.
32
33
34
35
36

37 *Design and Materials*

38
39 Experiment 2 was a 2×2 (Empathy [high-empathy, no-empathy] \times Effort-status
40
41 [high-status, low-status]) between-subject experimental design. The critical dependent
42
43 variable was also participants' PoC in the PGG, of which 10 rounds in total, as with
44
45 Experiment 1. The digit cancellation test is a 23×40 matrix which was generated using
46
47 Matlab software (<http://uk.mathworks.com/products/matlab/>). There are 106 number threes in
48
49 total in the matrix, and participants were presented with matrix on a printed A4 piece of paper
50
51 and had to cross out as many number threes in two minutes. The score 94 was obtained based
52
53 on piloting the test. Prior to the pilot, the number was set at 84 since this was the median of a
54
55
56
57
58
59
60

1
2
3 group ($n = 55$, $Mdn = 84.00$, $M = 80.17$, $SD = 1.58$) conducting the experiment. However,
4
5 when initially carrying out the experiment, most participants (10 out of 12) achieved above
6
7 the 84 threshold, and so this means that most of the participants were performing at ceiling,
8
9 and so this threshold did not meaningfully discriminate performance. Therefore, after these
10
11 12 participants, we increased the threshold to 94, which was calculated based on mean
12
13 achieved by the piloted high-status group ($n = 10$, $Mdn = 95.5$, $M = 93.60$, $SD = 5.13$). Those
14
15 achieving a score equal to or above 94 were allocated to the high-status condition, and those
16
17 scoring less than 94 were allocated to the low-status condition. Thereafter the allocation to
18
19 empathy and no-empathy conditions was determined randomly. All participants were
20
21 informed of the allocation procedure prior to performing the test. With the exception of the
22
23 allocation procedure, in all other respects Experiment 2 was identical to Experiment 1.
24
25
26

27 **Procedure**

28
29 In Experiment 2, participants were required to perform a digit cancellation test instead
30
31 of picking a color ball in a black box to allocate them into high-status or low-status
32
33 conditions. Apart from this, all other experimental procedures were exactly the same as the
34
35 Experiment 1.
36
37
38

39 **Results**

41 ***Empathizing Manipulation Effectiveness Check***

42
43 The same analysis conducted in Experiment 1 was conducted on empathy judgments
44
45 for Experiment 2 on the no-empathy ($n = 52$) and high-empathy ($n = 46$) conditions. There
46
47 was a large effect ($d = 1.31$) indicating that empathy judgments were higher in the high-
48
49 empathy condition ($M = 6.20$, $SD = 1.73$) compared to the no-empathy conditions ($M = 3.97$,
50
51 $SD = 1.67$).
52
53
54
55
56
57
58
59
60

Empathy & Status manipulation

The mean PoC in each of the 10 rounds in the four conditions for Experiment 2 are shown in Figure 2; the overall mean PoC for each condition is: high-status no empathy ($M = .38$, $SD = .21$), low-status no empathy ($M = .47$, $SD = .21$), high-status empathy ($M = .31$, $SD = .21$), low-status empathy ($M = .60$, $SD = .21$).

The same analyses were conducted as Experiment 1. There was a medium to large effect found for the interaction between effort-status and empathy for PoCs on the first round ($\eta_p^2 = .18$). **There was a very small effect** of empathy on first round PoCs ($\eta_p^2 = .01$), but there was a medium effect of effort-status ($\eta_p^2 = .14$). A $10 \times 2 \times 2$ (Round [1:10]), within-subject variable \times (Empathy [high-empathy, no-empathy]) \times (Effort-status [high-status, low-status]) between-subject variables repeated-measures ANOVA was conducted (See Figure 2). There was a small effect found in the interaction between effort-status and empathy ($\eta_p^2 = .06$). There was **very small** effect of empathy ($\eta_p^2 = .004$). There was a medium to large main effect of effort-status on PoCs across rounds ($\eta_p^2 = .18$). Since there was some evidence of interaction effects, post-hoc pairwise comparisons were conducted, which found that in the high-empathy condition, the effect was large and suggested that the low-status condition contributed more than those in the high-status condition, ($\eta_p^2 = .20$); in the no-empathy condition, the effect on PoCs across rounds based on differences in status was small ($\eta_p^2 = .03$) also suggesting that the low status condition contributed more than the high-status condition. There was a small interaction effect between round and effort-status ($\eta_p^2 = .03$), and a small main effect of round suggesting that contributions decreased across rounds, ($\eta_p^2 = .04$).

Insert Figure 2 about here

In addition, we compared the PoCs contributed across rounds for high-status conditions in which their status was gained through effort (Experiment 2), with high-status

1
2
3 conditions in which their status was gained through chance (Experiment 1). A 10×2 (Round
4 [1:10]), within-subject variable $\times 2$ (Gained-status [high-status-effort, high-status-chance])
5
6
7 between-subject variables repeated-measures ANOVA was conducted. There was a small
8
9 effect ($\eta_p^2 = .05$) suggesting that those in the high-status-effort conditions ($n = 47$, $M = .37$,
10
11 $SD = .22$) contributed less than the high-status-chance conditions ($n = 49$, $M = .46$, $SD = .18$),
12
13

14 Discussion

15
16 Consistent with Experiment 1, Experiment 2 supported prediction 1. In general, those
17
18 in the low-status group showed more cooperation than those in the high-status group as
19
20 indexed by the level of tokens contributed in the PGG. In addition, in support of prediction 2,
21
22 the evidence suggested that when high-status was achieved through effort, contributions were
23
24 consistently lower than when achieved through chance. **While there were very small effects**
25
26 **in support of prediction 3 consistent with Experiment 1**, Experiment 2 did however reveal
27
28 an interaction between empathy and status. For those in the low-status group high-empathy
29
30 condition there was evidence that they showed greater levels of cooperation than those in the
31
32 low-status no-empathy group; **there was also very small effects suggesting the same**
33
34 **pattern in the no-empathy status conditions. Thus far, given the very small effects**
35
36 **revealing an association between empathy and cooperation in** both Experiment 1 and 2,
37
38
39 Experiment 3 was conducted to fully explore the empathy-cooperation link.
40
41
42
43

44 Experiment 3

45
46 Experiment 3 was designed to examine the link between empathy and cooperation
47
48 under equal resources conditions (Yamamoto & Takimoto, 2012) **as a way to establish the**
49
50 **extent to which the empathy-cooperation link is reliable independent of the manipulation of**
51
52 **status.**
53
54
55
56
57
58
59
60

Method

Participants

Sixty-nine volunteers (47 females and 22 males) were recruited from Queen Mary University of London. Participants were aged between 18 to 56 years old ($M = 22.68$, $SD = 5.65$). On completion of the experiment, participants received between £6 and £15 ($\$8.41$ to $\$21.02$) based on their performance in the linear PGG (25 tokens = £1). They were randomly allocated to one of three conditions (high-empathy, low-empathy, no-empathy) by a randomly generated number in excel.

Design and Materials

Experiment 3 was a between-subject design with 3 levels (empathy [high-empathy, low-empathy, no-empathy]) experimental design, and the critical dependent variable was participants' PoC per round in the main PGG, of which there were 10 rounds in total. The high-empathy and no-empathy conditions were the same as in Experiment 1 and Experiment 2. In the low-empathy condition participants read the same profiles as those in the high-empathy condition, but they were instructed, "While you are reading this, try to take an objective perspective towards what has just been described. Try to remain as objective and detached as possible." This served as an intermediate level of empathy induction based on previous empathy induction techniques (1999). With this exception, and the fact that all participants received the same endowment as the virtual players on each round [20,20,20,20], in all other respects Experiment 3 was the same as Experiment 1 and 2.

Procedure

After the participants completed reading the information sheet and signed the consent form, participants were randomly assigned into one of three conditions. In all other respects Experiment 3 was the same as Experiment 1 and 2.

Results

Empathizing Manipulation Effectiveness Check

For Experiment 3, a one-way ANOVA was conducted using mean estimates of empathy. The analysis revealed a main effect of empathy, suggesting that across the three conditions participants self-assessed empathizing varied ($\eta_p^2 = .18$). Self-reported empathizing was higher ($d = .69$) in the high-empathy ($M = 5.40, SD = 1.41$) compared with the no-empathy condition ($M = 4.04, SD = 2.37$), and higher ($d = 2.09$) in the low-empathy ($M = 5.93, SD = 1.77$) compared to no-empathy. There was also a difference between high and low-empathy conditions, suggesting that self-assessed empathising was higher ($d = .33$) in the low empathy condition compared to the high empathy condition.

Empathy manipulation

The mean PoC in each of the 10 rounds in the four conditions for Experiment 3 are shown in Figure 3; the overall mean PoC for each condition is: high empathy ($M = .44, SD = .22$), low-empathy ($M = .44, SD = .22$), and no empathy ($M = .47, SD = .22$).

Insert Figure 3 about here

First round data for Experiment 3 was used for one-way ANOVA to explore the main effect of empathy, for which there was a very small effect ($\eta_p^2 = .001$). Next a 3 x 10 (Round ([1:10], within-subject variable × Empathy [high-empathy, low-empathy, no-empathy] between subjects variable) repeated-measures ANOVA was conducted. There was a medium main effect of round, ($\eta_p^2 = .13$), suggesting that contributions generally decreased across rounds. There was a very small main effect of empathy on PoCs across rounds ($\eta_p^2 = .004$) (see Figure 4), and there was a very small interaction effect between round and empathy ($\eta_p^2 = .01$) (see Figure 3)

Overall Deception Success Check

At this stage we **examine** data from all three experiments in order to assess the extent to which the deception introduced in our study impacted on any **of** the behavioral measures we recorded. Taking all of the participants into account across all three experiments we had 184 data points having excluding those reported 'unsure' in our debrief questionnaire, or where there was missing data. Of the 184 data points we include in our analyses participants either answered Yes, they believed that the experimental set-up was as we had described (i.e. that they were playing with 3 other real participants), or No they did not believe our experimental set-up, and were unconvinced that they were interacting with 3 other participants in the PGG. Across all three experiments, 40% of participants responded No in our debrief questionnaire. A Round (1-10) x Deception success (yes 1, no 2) repeated-measures ANOVA was conducted. **The results found that the interaction between round and deception revealed a very small effect on contributions in PGG ($\eta_p^2 = .00001$).**

Discussion

Consistent with Experiments 1 and 2, Experiment 3 found very small effects in support for Predictions 3, and there was also a very small effect in support for Prediction 4. In line with previous studies (Batson & Ahmad, 2001; Batson & Moran, 1999; Rumble et al., 2010), we used a similar design in which one participant is interacting with 3 fictitious individuals. The very small effects revealed that this did not adversely impact the pattern of contributions in the three experiments included in this study. Nevertheless, to fully test our manipulations regarding status and empathy, we considered it of importance to examine the extent to which our findings would replicate in an experiment in which participants were interacting with real players.

Experiment 4

Experiment 4 used a 2-player PGG, in which the set up was the same as a typical 4-player game, but with 2-players, in which status (low-status, equal-status) was achieved based on chance using the same procedure as that of Experiment 1. The rationale for the changes in design are as follows. First, we consider it of important to examine the extent to which our pattern of results generalize to situations in which real players are facing a genuine social interaction with other real players. Second, thus far we have not conducted a direct comparison between a control status condition with a status manipulation. Therefore, given that we found **small to medium effects** for low status conditions in Experiment 1 and 2, we examined the extent to which low status conditions contributed more than conditions in which the endowment was the same for both players (i.e. equal-status).

Method

Participants

One hundred and sixty volunteers (87 females and 73 males) were recruited from Queen Mary University of London. The mean age of the participants was 22.86 years (range from 18 to 50; $SD = 4.97$). The payments for participating were the same as Experiment 1 and 2.

Design and Materials

Experiment 4 was a 2×2 (Empathy [high-empathy, no-empathy] \times chance-status [low-status, equal-status]) between-subject experimental design. The critical dependent variable was also participants' PoC in the PGG, of which there were a 10 rounds in total, as with Experiment 1 and 2. The basis on which participants were allocated to the following four conditions was the same as Experiment 1: high-status no-empathy, high-status empathy, low-status no-empathy, and low-status empathy.

Procedure

The pairs of participants were tested together in a sound-proofed experimental cubicle facing two individual computer monitors with a dividing folding screen. Participants were randomly allocated to Player A or Player B based simply on the first person to enter the cubicle; the first person was allocated to Player A, and the other person was allocated to Player B. After reading the information sheet and signing the consent form, one of the two players was asked to volunteer to pick a ball from a black box without looking. If they picked the red ball, the participant was assigned as equal-status [20 tokens; 20 tokens]; if they picked the blue ball, they were assigned as low-status [10 tokens: 20 tokens]. After that, they were allowed to start the experiment. Once seated and allocated to their roles, all remaining procedures were identical to Experiment 1.

Results

Empathizing Manipulation Effectiveness Check

An independent-samples *t*-test was conducted on judgments regarding the extent to which participants empathized with the experiences of the other player in the no-empathy and high-empathy conditions. Empathizing judgments were higher ($d = -1.25$) in the high-empathy condition ($n = 80$, $M = 7.40$, $SD = 1.57$) compared to the no-empathy condition ($n = 80$, $M = 4.75$, $SD = 2.53$).

Empathy manipulation

The mean PoC in each of the 10 rounds in the four conditions for Experiment 4 are shown in Figure 4; the overall mean PoC for each condition is: equal-status no empathy ($M = .52$, $SD = .30$), low-status no empathy ($M = .56$, $SD = .26$), equal-status empathy ($M = .56$, $SD = .31$), low-status empathy ($M = .69$, $SD = .29$).

Insert Figure 4 about here

Looking at differences between conditions across both players, based on first round contributions. A Univariate analysis was conducted and **revealed a very small main effect** of empathy ($\eta_p^2 = .000001$). There was a small main effect of status, ($\eta_p^2 = .02$) suggesting that those in the low-status condition ($M = .62$, $SD = .36$) contributed more than the equal-status condition ($M = .60$, $SD = .36$). There **was a very small effect of** an interaction between empathy and status ($\eta_p^2 = .001$).

Focusing on PoCs across rounds, a $10 \times 2 \times 2$ (Round [1:10]), within-subject variable \times (Empathy [high-empathy, no-empathy]) \times (Chance-status [low-status, equal-status]) between-subject variables repeated-measures ANOVA was conducted (see Figure 4). There **was a very small effect** of an interaction between chance-status and empathy ($\eta_p^2 = .006$). There was a small main effect of empathy ($\eta_p^2 = .02$), and a small main effect of status ($\eta_p^2 = .02$). There was also a small main effect of round ($\eta_p^2 = .03$), suggesting that contributions generally decreased across rounds. Overall, we found that across rounds there was a trend suggesting that the low-status group contributed more to the group pot compared to the equal-status group.

Looking at contributions across rounds, for Player A only, a $10 \times 2 \times 2$ (Round [1:10]), within-subject variable \times (Empathy [high-empathy, no-empathy]) \times (Condition [low-status; equal-status]) between-subject variables repeated-measures ANOVA was conducted. There was small effect of an interaction between chance-status and empathy ($\eta_p^2 = .02$). There was a small main effect of empathy ($\eta_p^2 = .05$), and a small main effect of status ($\eta_p^2 = .03$). There was also a small main effect of round ($\eta_p^2 = .04$). Again, we found that across rounds there was a trend suggesting that low-status players contributed more to the group pot compared to the equal-status players.

1
2
3 The same analyses were conducted for Player B. There was small effect of an
4 interaction between chance-status and empathy ($\eta_p^2 = .02$). There **was a very small** main
5 effect of empathy ($\eta_p^2 = .008$). There was a small main effect of round ($\eta_p^2 = .06$). There was
6 also a small main effect of status ($\eta_p^2 = .02$) suggesting that low-status players contributed
7 more to the group pot compared to the equal-status players.

13 Discussion

14
15
16 Experiment 4 was designed to extend the findings reported in Experiment 1 and 2
17 under conditions in which participants were taking part in a genuine social interaction in a
18 PGG. Experiment 4 replicated the findings of Experiment 1 in a 2-player PGG. Overall, the
19 findings suggest that those in the low-status group contributed more than those in the equal-
20 status group. There was also some evidence to suggest across rounds, the empathy induction
21 method lead to increases in contributions for the empathy conditions compared to the no
22 empathy induction conditions.

33 Summary and Concluding Discussion

34
35
36 The main objective of this study was to examine the following two questions: 1) To
37 what extent are pro-social behaviors impacted in situations in which the resources gained
38 (either through chance or effort) by one individual in the group differ? 2) To what extent does
39 empathy promote pro-social behaviors given the way in which one individual in a group
40 achieves their status (i.e. through chance or effort)? Overall, the findings from four
41 experiments suggest that, individuals with less resources than their group members (low-
42 status) tend to be more cooperative compared to individuals that have more resources than
43 their group members (high-status), and those with equal resources (equal-status). In addition,
44 we found that any attempts to induce empathy in individuals resulted **in very small effects**
45 **on** cooperative behaviors. In the discussion that follows, we consider the evidence

60

1
2
3 specifically in relation to the four predictions we tested, and the implications of our findings
4
5 with respect to previous theoretical and empirical work.
6

7 **Prediction 1:** Informed by prior empirical (Bennett, 2012; Cote, House, & Willer,
8 2015; Guinote, et al., 2015; Piff, et al., 2010) and theoretical work (Kafashan et al., 2014)
9 examining the relationship between status and pro-social behaviors, we predicted the
10 following: Overall low-status individuals will show greater cooperation, as evidenced
11 through contributions to a public good, compared to high-status individuals. We found
12 support for this in Experiment 1 in which status was gained through chance, and in
13 Experiment 2 in which status was gained through effort. In addition, we found support for
14 this in Experiment 4 in which low-status conditions tended to contribute more compared to
15 equal-status conditions.

20
21
22
23
24
25

26 As Kafashan et al., (2014) proposed, possessing status can change the perceived costs
27 and benefits of engaging in pro-social behavior, and so we consider in more depth how this
28 emerged in our present pattern of findings. First, it may be the case that low-status groups
29 behaved cooperatively because they may have outweighed the cost of increasing
30 contributions against the gains of increasing their reputation amongst the group. This is
31 consistent with work suggesting that low status individuals do indeed try to improve their
32 standing in a social hierarchy (Willer, 2009b), or as a means of affiliating themselves with a
33 perceived group identity (Kraus, Piff, & Keltner, 2009). Second, it may also be the case that
34 the cost of behaving more cooperatively was outweighed by the benefits of demonstrating
35 compassion to other group members. Consistent with this, there is evidence to suggest that,
36 compared to high-status groups, there is a stronger association between low-status individuals
37 and expressions of charitable and helping behaviors (Stellar, Manzo, Kraus, & Keltner,
38 2012). Moreover, this also implies that compared to high-status groups, low-status groups
39 have stronger feelings of compassion because they are more sensitive to a sense of fairness.

55
56
57
58
59
60

1
2
3 This may also potentially help to explain why it is that we found an effect of empathy on
4 cooperation was high localized to low-status groups in Experiment 2 in which status was
5 gained by effort. As mentioned, one reason may be that this group show greater compassion
6 and are more sensitive to fairness (Kraus et al., 2009), but this doesn't explain why empathy
7 **revealed larger effects** in the low effort-status groups (Experiment 2) than low chance-status
8 groups (Experiment 1 and 4).
9
10
11
12
13
14

15
16 One possible explanation is based on the differences in control that people
17 experienced (Osman, 2014). When the mechanism by which resources are allocated is via
18 *chance*, then clearly there is no sense of control or real ownership that people can feel with
19 regards to having more or less than others (unless one experiences an illusion of control). In
20 contrast, when resources are achieved through *effort*, then people are likely to feel greater
21 ownership and responsibility over the resources they acquired, and that the manner by which
22 they acquired them was under their control. Some have argued that limited control over the
23 attainment of resources leaves low-status individuals, as compared to high-status individuals,
24 more dependent on others (Piff et al., 2010), which in turn encourages more cooperative
25 behavior. If experienced lack of control amplifies cooperation because now there is a
26 dependence on others to show cooperative behaviors, taken together with some sense of
27 empathy, then we would expect those in the low-status group to show greater cooperative
28 behaviors than the high-status group in the chance-status condition, which is also what we
29 found. What is hard to determine is whether differences in behavior resulting from acquiring
30 status through effort or chance is a matter of degree (i.e. levels of control), or a matter of kind
31 (i.e. control vs. no control).

37
38
39
40
41
42
43
44
45
46
47
48
49

50
51 **Prediction 2:** Again, informed by previous empirical work (e.g., Hays & Blader,
52 2016), and specifically extending the theoretical claims made by Kafashan et al.'s (2014) bi-
53 directional causation account of status and cooperation, we considered the extent to which the
54
55
56
57
58
59
60

1
2
3 costs and benefits of cooperative behavior was impacted by the way in which status was
4
5 achieved. Based on this, we tested the following: If perceived entitlement plays a role, then
6
7 high status individuals will feel more entitled when they achieve their status through effort
8
9 than when achieved through chance, and so will display lower levels of cooperation through
10
11 contributions to a public good compared to high-status individuals achieving their status
12
13 through chance. To this end, we found support for this. When comparing the contributions
14
15 across rounds, those in the high-status condition that had earned their status via effort
16
17 contributed consistently less than those that had achieved their status via chance. This
18
19 suggests that, consistent with prior work suggesting that high-status individuals often make
20
21 pro-social choices with respect to their perceived entitlement and self-interests (Cherry &
22
23 Shogren, 2008; Cote, House, & Willer, 2015; Hays & Blader, 2016), those that had earned
24
25 their status considered the costs of contributing higher than those that gained their status
26
27 chance.
28
29
30

31 **Prediction 3:** There is considerable work suggesting a role for empathy in promoting
32
33 pro-social behaviors, particularly cooperation (Batson, 2011; Cialdini, et al., 1982; Rumble et
34
35 al., 2010; Yamamoto & Takimoto, 2012), and several empirical studies supporting this view
36
37 (Allsop, et al., 2002; Batson & Moran, 1999; Cialdini et al., 1987; Eimontaite, et al., 2013;
38
39 Fultz, et al., 1986; Oswald, 1996, 2002; Pavey, et al., 2012; Stürmer, et al., 2006). Given the
40
41 general theoretical claims that, while they differ with respect to the underlying mechanism
42
43 that drives the relationship, generally empathy promotes cooperation. Therefore, we tested
44
45 the following: Overall, when perspective taking inducements of empathy are present,
46
47 irrespective of status manipulations, there should be greater displays of cooperation through
48
49 contributions to a public good compared to no-empathy inducements. We **found very small**
50
51 **effects** of empathy on cooperative behaviors in the PGG in Experiments 1, 2. In fact, on this
52
53 basis Experiment 3 was run specifically to test the role of empathy induction without the
54
55
56
57
58
59
60

1
2
3 status manipulation, to check whether this may have muted the expression of empathy on
4
5 cooperation. **Here too we found very small effects.** In Experiment 4 we did find a small
6
7 effect suggesting that empathy promoted cooperation.
8

9
10 First of all, as discussed earlier, there is also evidence that challenges this received
11
12 view, suggesting instead that **empathy has a limited** (LV et al., 2015; Oswald, 1996; Warren
13
14 & Walker, 1991; Xu et al., 2012, Study 2), or even a negative effect on pro-social behaviors
15
16 (Epley, et al., 2006; Gilin et al., 2012). **So, in this light, our findings are consistent with**
17
18 **evidence suggesting weak effects of empathy on cooperation.** Second, given that we did
19
20 **find small effects** of the impact of empathy induction on cooperation in Experiment 2, albeit
21
22 highly localized to the low-status group, as well as in Experiment 4, we consider the basis for
23
24 this.
25

26
27 One key reason for the **very small** impact of empathy on cooperation may be
28
29 explained by the fact that empathy inducing altruism operates effectively on a local
30
31 individual level rather than on a multiple agent level. Thus, when the target of empathetic
32
33 feelings is ambiguous, then this leads to a “escaping effect” (Cameron & Payne, 2011) such
34
35 that the degree of compassion people feel tends to decrease as the number of people in need
36
37 increases. “One death is a tragedy; one million is a statistic.” This suggests that there may be
38
39 an upper bound to empathizing abilities, which is consistent with evidence demonstrating that
40
41 reliably inducing empathy to increase cooperation is most commonly found in dyads (Batson
42
43 & Moran, 1999). Our pattern of findings from Experiment 4 support this speculation.
44
45

46
47 An alternative simple explanation might be that our dependent variable was not
48
49 sufficiently sensitive enough to detect a weak empathy manipulation. There are two simple
50
51 counters to this limitation, the first is that previous studies, discussed in the next point, have
52
53 used the same experimental methods and have detected an effect of empathy, albeit a
54
55 temperamental one. The second is that, the same dependent variable used in the three
56
57
58
59
60

1
2
3 experiments in which status was manipulated, was sufficiently sensitive enough to detect
4
5 **small to large** effects of status on contributions in the PGG.
6
7

8 A further reason for why our empathy induction method **only very weakly promoted**
9 cooperative behaviors was because of the particular method we used. The empathy induction
10 method adopted here, and in many other studies, is the perspective-taking method in which
11 participants are instructed to consider the experiences of others via descriptions of people's
12 suffering (Allsop et al., 2002; Cialdini et al., 1987; Eimontaite et al., 2013; Pavey et al., 2012;
13 Stürmer et al., 2006), a form of cold empathy (Loewenstein, 2000; Paal & Bereczkei, 2007).
14 This means that they may have been successful in understanding the behaviors and emotional
15 states of others, but they did not necessarily adopt the same emotional states of others. This is
16 in contrast to experimental methods designed to induce hot empathy in which participants are
17 presented with videos of people experiencing bad situations (Oswald, 1996), or even invited
18 to directly helping others in need (Oswald, 2000), that more directly induces strong feelings
19 of sadness or empathic concern. Therefore, it may simply be the case, that hot empathy which
20 induces actual changes in emotional states is a more effective means of promoting
21 cooperative behaviors than cold empathy. Though one caveat to this is that, the mixed
22 findings concerning the impact of empathy on cooperation specifically concern perspective-
23 taking methods, in which some studies show a positive influence, and others do not. Which
24 suggests that either the technique is unreliable, or the general impact of empathy on
25 cooperation is simply less straightforward than has been claimed (Yamamoto & Takimoto,
26 2012).
27
28
29
30
31
32
33
34
35
36
37
38
39
40
41
42
43
44
45
46
47
48

49 **Prediction 4:** For this reason discussion previously, we sought to test Yamamoto and
50 Takimoto's (2012) fairness and empathy account, in which they claim that empathy promotes
51 prosocial behaviors under conditions of fairness. From this, we tested the following
52 prediction: If a sense of fairness is used to complement empathy in supporting cooperative
53
54
55
56
57
58
59
60

1
2
3 behaviors, then under conditions in which empathy inducements are present, there should be
4
5 evidence of an impact of empathy on cooperation under conditions in which the status of
6
7 individuals is equal (i.e. fair), rather than unequal (unfair). We found **very small effects** in
8
9 support for this prediction. In the equal resource conditions in which everyone was endowed
10
11 with the same number of tokens in the group (Experiment 3, and Experiment 4, equal status
12
13 group), there **were very small to small effects** to suggest an effect of empathy on
14
15 cooperation. Again, one speculation for this is that the type of empathy inducement technique
16
17 that was used in this study was not strong enough as compared to methods that induce hot
18
19 empathy. A second more nuanced explanation is that, rather than promote cooperation, our
20
21 empathy manipulation, in association with other factors, helped to stabilize cooperative
22
23 behaviors across rounds. However, in all four experiments, contributions reduced across
24
25 rounds, and there **were only very small effects to suggest** an interaction with empathy and
26
27 contributions across rounds.
28
29

30
31 Another contributing factor regarding the **very small effect** of empathy on
32
33 cooperation in our study concerns a key novel strength of the present study regarding the use
34
35 of real financial incentives. When developing our paradigm, we took heed of critical
36
37 comments from the behavioral economics literature regarding incentives schedules that are in
38
39 line with the aims of the specific task or game (Hertwig & Ortmann, 2001). In contrast,
40
41 participants in many previous studies which found empathy-induced cooperation obtained
42
43 either a fixed show-up fee (Xu et al., 2012) or course credits for their attendance (Batson et
44
45 al., 1995; Batson & Moran, 1999; Rumble et al., 2010). In our experiments participant
46
47 payments were directly associated with their choice-behavior. Even though empathy-induced
48
49 altruism may appear to promote cooperation (Batson & Moran, 1999), it may only be the case
50
51 for studies in which payment is not dependent on actual choice behavior. Thus, the cost of
52
53
54
55
56
57
58
59
60

1
2
3 cooperative behavior may be actually rather high such that empathy is not strong enough to
4
5 override a self-maximizing strategy (Ma-Kellams & Blascovich, 2013).
6

7 In summary, status and the way in which it is achieved (chance, effort) appeared to be
8
9 a key determining factor in the level of cooperation observed in a multiplayer game. In
10
11 particular, those with less resources than their counterparts tended to be more cooperative
12
13 than those with more resources than their counterparts. The present study found **very small**
14
15 **effects** to support the general intuition of the impact of empathy on cooperation under
16
17 previously unexplored conditions of inequality of resources. One reason for the **very small**
18
19 **effect** of empathy on cooperation under conditions in which people gain different levels of
20
21 status, is that strong emotional experiences of empathic concern towards others need to
22
23 ameliorate more salient factors, such as, for those with high status, maintaining personal
24
25 finances achieved through effort as well as chance.
