Just Accepted

“Just Accepted” manuscripts have been peer-reviewed and accepted for publication. They are posted online prior to technical editing, formatting for publication and author proofing. The American Chemical Society provides “Just Accepted” as a service to the research community to expedite the dissemination of scientific material as soon as possible after acceptance. “Just Accepted” manuscripts appear in full in PDF format accompanied by an HTML abstract. “Just Accepted” manuscripts have been fully peer reviewed, but should not be considered the official version of record. They are citable by the Digital Object Identifier (DOI®). “Just Accepted” is an optional service offered to authors. Therefore, the “Just Accepted” Web site may not include all articles that will be published in the journal. After a manuscript is technically edited and formatted, it will be removed from the “Just Accepted” Web site and published as an ASAP article. Note that technical editing may introduce minor changes to the manuscript text and/or graphics which could affect content, and all legal disclaimers and ethical guidelines that apply to the journal pertain. ACS cannot be held responsible for errors or consequences arising from the use of information contained in these “Just Accepted” manuscripts.

ABSTRACT

The focal adhesion tyrosine kinase (PTK2) is often over-expressed in human hepatocellular carcinoma (HCC) and several reports have linked PTK2 depletion and/or pharmacological inhibition to reduced tumorigenicity. However, the clinical relevance of targeting PTK2 still remains to be proven. Here we present two highly selective and functional PTK2 PROTACs utilizing VHL and cereblon ligands to hijack E3 ligases for PTK2 degradation. BI-3663 (cereblon-based) degrades PTK2 with a median DC_{50} of 30 nM to > 80 % across a panel of eleven HCC cell lines. Despite effective PTK2 degradation, these compounds did not phenocopy the reported anti-proliferative effects of PTK2 depletion in any of the cell lines tested. By disclosing these compounds, we hope to provide valuable tools for the study of PTK2 degradation across different biological systems.

Introduction

Focal adhesion tyrosine kinase (PTK2) is a cytoplasmic protein tyrosine kinase that is overexpressed and activated in many types of advanced-stage solid cancers. PTK2 is reported to play an important role in adhesion, spreading, motility, invasion, metastasis, survival, angiogenesis, epithelial to mesenchymal transition (EMT), cancer stem cells and the tumour microenvironment^{1,2}. Overexpression and activation of PTK2 is associated with several human malignant diseases, including colorectal³, ovarian⁴, esophageal⁵ and hepatocellular carcinoma (HCC)⁶ and is correlated with poor overall patient survival^{7, 8}. Hepatocellular carcinoma (HCC) is the most common type of liver cancer in humans, accounting for 70–85 % of primary liver malignancies, and is the third leading cause of cancer-related death worldwide^{9, 10}. HCC is associated with an extremely poor prognosis since it is often diagnosed at advanced stages, restricting the currently available therapeutic options to either surgical resection or liver transplantation^{11, 12}. Several reports link PTK2 depletion or pharmacological inhibition of its kinase activity to reduction of *in vitro* and *in vivo* tumorigenicity in HCC models^{13, 14}. However, the disconnect between modulation of intracellular PTK2 autophosphorylation and growth inhibition as well as the often suboptimal selectivity profile of the inhibitors used makes it difficult to link the reported blockade of HCC tumour initiation and maintenance to PTK2 inhibition.

We previously described BI-853520, a novel ATP-competitive inhibitor distinguished by high potency and selectivity^{15, 16}. BI-853520 inhibits PTK2 autophosphorylation in cancer cell lines and blocks anchorage-independent proliferation with single digit nmol/L potency. In contrast, cells grown in conventional surface (2-D) culture were found to be 1,000-fold less sensitive to BI-853520. These findings are in keeping with the described role of PTK2 in integrin mediated

1
2
3 signaling^{2, 17}. We reasoned that ligands derived from BI-853520 would be suitable to develop
4
5 PROTACs (PROteolysis TArgeting Chimeras) and compare the potential anti-oncogenic effects
6
7 of PTK2 depletion as compared to inhibition of its kinase activity¹⁸.
8
9

10 PROTACs are bifunctional degrader molecules composed of a ligand for the target protein
11
12 linked to a module that recruits an E3 ligase^{19, 20}. PROTACs represent an emerging therapeutic
13
14 strategy to use small molecules to deplete a protein by repurposing the ubiquitin-proteasome
15
16 system^{21, 22}. Upon formation of a ternary complex target:PROTAC:E3 ligase²³⁻²⁵, the protein of
17
18 interest is ubiquitinated and subsequently degraded by the proteasome. Compared to
19
20 pharmacological inhibition of the kinase function, protein degradation more closely resembles
21
22 genetic approaches to interfere with PTK2 expression in HCC models. Moreover, PROTAC
23
24 molecules can add a layer of target selectivity beyond that expected from the constitutive binding
25
26 ligands, thus providing highly selective degraders with potentially reduced off-target effects²⁵⁻²⁸.
27
28
29

30 The most common E3 ligases currently recruited using PROTACs are the von Hippel-Lindau
31
32 (VHL) protein complex CRL2^{VHL} and the cereblon (CRBN) complex CRL4^{CRBN}. PROTACs
33
34 consisting of the same target ligand but employing either VHL or CRBN ligands can exhibit
35
36 different degradation selectivity and efficacy^{26, 29-31}. Emerging evidence suggests that it might be
37
38 beneficial to develop parallel chemical series hijacking different E3 ligases. First, expression of
39
40 the recruited E3 ligase and intrinsic activity may be context-dependent and vary widely amongst
41
42 cell- and tissue types³². Second, resistance mechanisms could potentially arise from loss of the
43
44 recruited E3 ligase, as demonstrated by the correlation between level of CRBN and response to
45
46 CRBN-recruiting drugs in multiple myeloma³³. Flexible choice of the recruited E3 ligase may
47
48 therefore aid targeted protein degradation.

3 Recently, the first PTK2 PROTACs have been reported. Conjugating the known pyrimidine-
4 based ALK inhibitors, TAE684 and LDK378, to the cereblon ligand pomalidomide led to the
5 discovery of the first small molecule degraders of ALK that concomitantly degrade, PTK2,
6 Aurora A, FER, and RPS6KA1³⁴. A PROTAC based on a highly promiscuous kinase inhibitor
7 was also reported to degrade PTK2 amongst 27 additional kinases³⁵. While both studies
8 demonstrate that PTK2 can be targeted by a PROTAC approach, they also clearly highlight the
9 need for more selective PTK2 PROTACs to address its role in cancer. Motivated by the potential
10 of targeting kinase-independent functions of PTK2 with a low molecular weight modality, we
11 initiated a PROTAC medicinal chemistry campaign to artificially recruit PTK2 to two different
12 E3 ligases.

26 Here, we show the synthesis and characterization of the first probe-quality PROTACs targeting
27 PTK2. Structure-guided conjugation of a highly selective PTK2 inhibitor to either a CRBN or
28 VHL ligand led to selective PTK2 degraders. We profiled both PROTACs for degradation
29 efficacy and anti-proliferative activity in a panel of HCC, tongue squamous cell carcinoma,
30 melanoma, pancreatic ductal adenocarcinoma and non-small cell lung cancer cell lines several of
31 which were recently shown to depend on expression of PTK2 by functional RNA interference
32 screening³⁶. Despite potent and complete degradation of PTK2, both degraders failed to show the
33 anticipated growth reduction beyond the effect of a PTK2 kinase inhibitor in these models.

45 **Results and Discussion**

46
47 We designed a set of PTK2 PROTACs recruiting the two E3 ubiquitin ligases, VHL and
48 CRBN, to test whether PTK2 can be targeted by targeted proteolysis. Making use of available E3
49 ligase ligands, we aimed at maximizing the chance of developing an active PTK2 degrader tool
50 compound. We selected the highly selective ATP competitive inhibitor BI-4464 (**1**, Scheme 1), a

1
2
3 close analogue of the 2-aminophenyl-4-phenoxy pyrimidine BI-853520¹⁵ currently being tested in
4
5 clinical trials as a PTK2 ligand. The choice of BI-4464 as a target ligand was driven by its high
6
7 binding affinity and exquisite selectivity across a large kinase panel (see also Figure 3). We
8
9 believe that this exceptional selectivity originates from a unique binding mode which seems to be
10
11 less tolerated by other kinases. To design a first generation of degraders, we inspected the crystal
12
13 structure of BI-4464 bound to the PTK2 kinase domain to identify suitable attachment points and
14
15 vectors for linker conjugation (Figure 1). The structure shows binding of the trifluoro-
16
17 aminopyrimidine moiety to the backbone nitrogen and carbonyl of cysteine 502 in the hinge
18
19 region via two hydrogen bonds. In addition, the oxygen of the dihydroindenone moiety forms
20
21 another hydrogen bond to the backbone nitrogen of aspartic acid 564. The N-methyl piperidine
22
23 group of BI-4464 was identified as solvent-exposed and not involved in any interactions with the
24
25 protein. We further selected **2**³⁷ and pomalidomide **3**,³⁸ (Scheme 1) as VHL and CRBN ligands,
26
27 respectively. Their terminal amino groups (Table 1 and Scheme 1) were conjugated *via* an amide
28
29 bond to the linker consisting of up to five PEG units without perturbing the interaction with the
30
31 E3 ligases, as previously demonstrated^{28, 31, 39, 40}.

Scheme 1. Chemical structures of BI-4464 ligand **1**, VHL ligand **2**^{37, 41, 42} and CRBN ligand **3**³⁸.

Figure 1. Structure of BI-4464 bound to PTK2 (PDB ID 6I8Z). Hydrogen bonds to cysteine 502 and aspartic acid 564 are depicted in blue.

To obtain the described compounds **6** and **8** (Table 1), a convergent synthesis was developed to connect **1a** to each E3 ligase ligand **2** and **3**. PEG linkers 1-5 (Scheme 2 shows an example of linker length three) were synthesized and profiled. The synthesis of ligand **1a** was carried out as outlined in Scheme 2. Aromatic nucleophilic substitution of the 4-chloropyrimidine **4** with 7-hydroxy-2,3-dihydroindan-1-one produced the carboxylic acid **1a**. Amide coupling of azido-PEG-3-propanoic acid and azido-PEG-3-acetic acid to the E3 ligase ligand **2** and **3** followed by catalytic hydrogenation produced the amines **5b**, **7b** and **10b** in good yields. The final PROTACs **6**, **8** and the cis-VHL analogue **11** were synthesized following amide coupling of the ligase linker conjugates **5b**, **7b** and **10b** with **1a**.

1
2
3 We next tested PTK2 degradation by all synthesized PROTACs (sampling linker lengths of up
4 to five ethylene glycol units) after 16 hours treatment of the human lung adenocarcinoma cell
5 line A549. PROTACs **6** (BI-3663) and **8** (BI-0319) were identified as the best degraders in the
6 CRBN and VHL series and characterized in greater detail. The CRBN-based PROTAC **6** (BI-
7 3663) degraded PTK2 potently ($DC_{50} = 27$ nM) with a maximally obtainable degradation at the
8 chosen experimental conditions of 95% (D_{max}) while the best VHL-based PROTAC **8** (BI-0319)
9 only achieved partial degradation ($D_{max} = 80$ %) and was less potent ($DC_{50} = 243$ nM) in A549
10 cells (Table 1 and Figure 2). Further, both PROTACs show a small apparent hook effect in A549
11 cells at 25 μ M. Consistent with VHL dependency, which requires the substituents of the
12 pyrrolidine in the VHL ligand in a *trans* configuration²⁸, degradation of PTK2 by **8** (BI-0319)
13 was abolished by switching the stereochemistry of the pyrrolidine substituents to the *cis*
14 configuration (**11**, **BI-4206**) (Figure 2A). Moreover, as predicted for neddylation-dependent E3
15 ligases such as VHL and CRBN, the NEDD8 inhibitor MLN4924⁴³ (MLN) inhibited degradation
16 of PTK2 by **6** (BI-3663) and **8** (BI-0319) (Figure 2A and B). Importantly, the PTK2 ligand **1**
17 itself did not affect PTK2 levels.

37 We assessed PTK2 target engagement *in vitro* to understand the effect of the linker and exit
38 vector on PTK2 inhibition of PROTACs **6** and **8**. As predicted from the structure-based design,
39 both PROTACs and the PTK2 ligand inhibited PTK2 *in vitro* with virtually identical potencies
40 ($IC_{50} = 18$ and 19 versus 17 nM for the PTK2 inhibitor **1**).

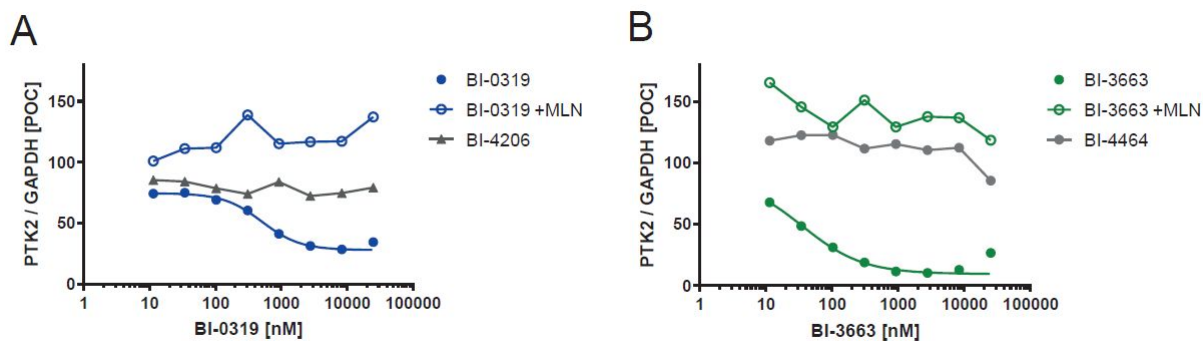

Figure 2. Characterization of BI-0319 and BI-3663 in A549 cells. A) A549 cells were treated with the indicated concentrations of BI-0319 in presence or absence of the NEDD8 inhibitor MLN4924 (MLN, 3 μ M) or an inactive stereoisomer (BI-4206) for 18 h. PTK2 levels were determined by protein capillary electrophoresis and normalized to GAPDH. Values are stated as percentages of DMSO controls (POC). B) A549 cells were treated with the indicated concentrations of BI-3663 in presence or absence of the NEDD8 inhibitor MLN4924 (3 μ M) or with the PTK2 inhibitor BI-4664 for 18 h. PTK2 levels were measured and are stated as in A.

In contrast to the previously published less selective PTK2 degraders^{34, 35}, we believe that a defining aspect of the PTK2 degraders described here is their high selectivity, which should enable validation of the relevance of PTK2 scaffolding functions in biologically relevant contexts. Indeed, of the 397 kinases tested in a kinase panel screening only 2 were inhibited by more than 90 % at 1 μ M (Figure 3). Interestingly, BI-0319 (**8**) is more selective than the already highly selective PTK2 TKI **1** (BI-4464). We assume that the kinase selectivity panel for BI-3663 (**6**) might be comparable to BI-0319 since both exit vector and linker are identical for a distance of nine atoms from the piperidine moiety of the PTK2 ligand

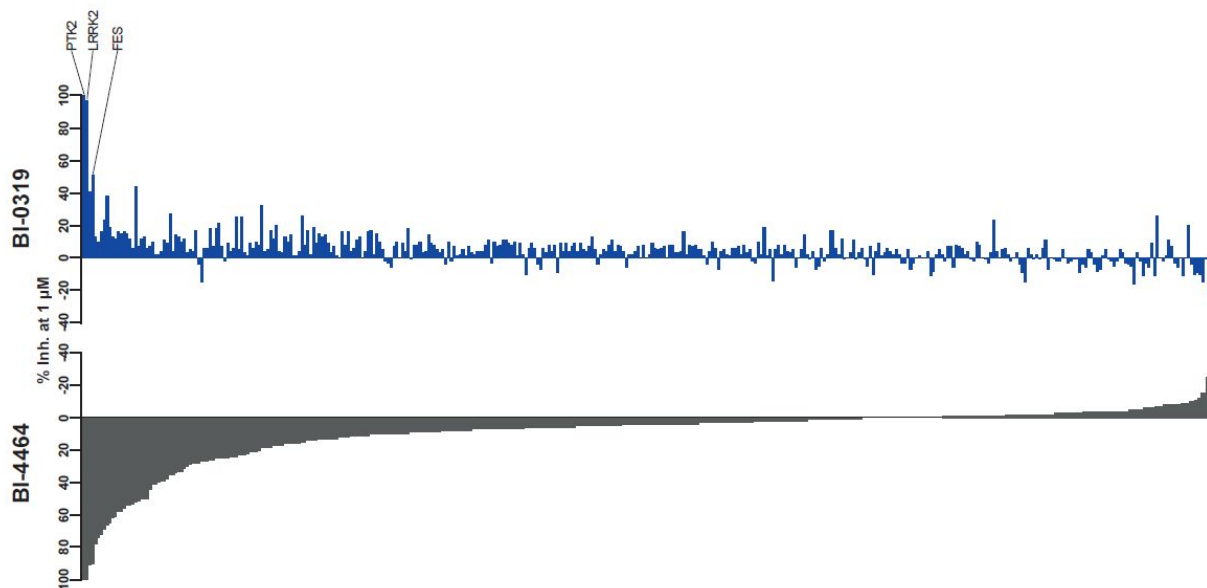

Figure 3. Kinase selectivity panels of the PTK2 ligand BI-4464 and VHL PROTAC BI-0319.

Bars indicate percent inhibition at 1 μ M of either compound.

We employed multiplexed isobaric tagging mass spectrometry to assess the cellular selectivity of BI-3663 (**6**) and BI-0319 (**8**) for PTK2 degradation and identify potential degradation off-targets in a quantitative and unbiased manner. Amongst the 6,008 proteins quantified in this analysis in A549 cells, PTK2 showed a distinct and significant change in abundance upon treatment with either PROTAC. (Figure 4 and Supplemental table 3). Neither BI-3663 (**6**) nor BI-0319 (**8**) induced any significant changes in abundance of other detectable kinases, thus confirming the high selectivity of both degraders within the kinase family. Of note, the two most prominent kinase off-targets of the inhibitor were not detected in this dataset. Interestingly BI-0319 (**8**) – but not BI-3663 (**6**) – also induced a significant change of PDE6D levels (Figure 4A), a finding corroborated by immunoblot in A549 cells (Supplemental figure 1).

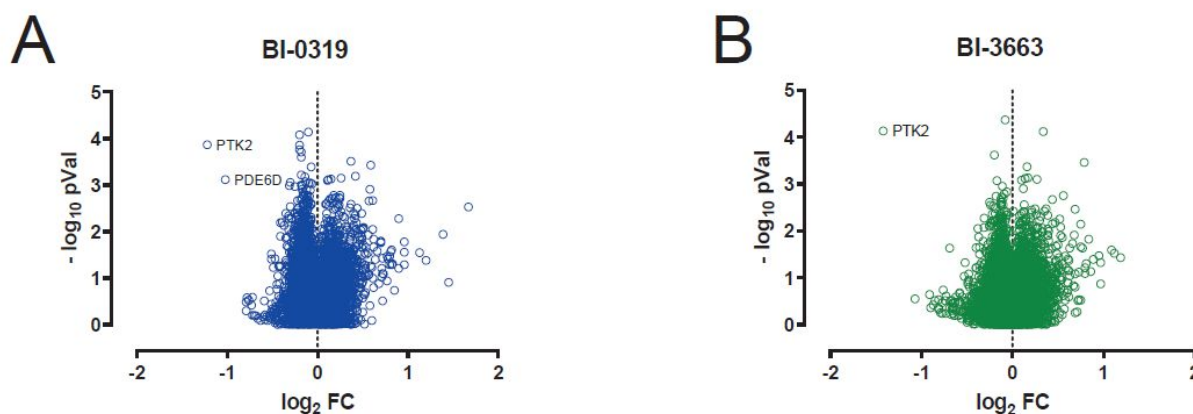

Figure 4. Total proteome analysis of A549 cells treated with 3 μ M of BI-0319 (A) or BI-3663 (B) for 18 h and compared to DMSO controls. Samples were run in biological triplicates and analyzed by mass spectrometry. Volcano plot displays \log_2 of fold-change in abundance versus $-\log_{10}$ of adjusted p value ($N = 3$).

Having established the high selectivity of both PROTACs, in particular of the CRBN-based BI-3663, we tested their potential to degrade PTK2 in a panel of eleven HCC cell lines (Table 3 and Supplemental figure 2 and 3). Both PROTACs show comparable degradation potencies and efficacies in the 11 HCC cell lines tested (BI-3663 mean $pDC_{50} = 7.45 \pm 0.60$ versus BI-0319 mean $pDC_{50} = 7.08 \pm 0.52$). Whereas PTK2 levels in cell lines such as SNU-398 were equally sensitive to treatment with both PROTACs, other cell lines, such as Hep3B2.1-7 exhibited a >10 fold difference of the potencies of **6** and **8** in cell-based PTK2 degradation assays, as observed for A549 cells during the profiling experiments (Figure 5 and Table 2).

It is not unexpected that heterobifunctional molecules unavoidably result in high molecular weight compounds, making it difficult to balance their physicochemical properties in a manner

1
2
3 consistent with acceptable permeability and solubility. While both PROTACs have a comparable
4
5 low aqueous solubility and high tPSA (241,243 Å²), PROTAC **6** has one hydrogen bond donor
6
7 (HBD) more than PROTAC **8**. The negative impact on permeability for **6** might be
8
9 compensated by the higher lipophilicity (ClogP 6.9 vs 3.8) however, the higher lipophilicity of **6**
10
11 also translates in higher PPB and lower free fraction (**6**: 4.0%, **8**: 11.3; Supplemental table 1).
12
13
14
15
16

17 As assessed by the Caco2 assay, both PROTACs exhibit low permeability and significant
18
19 efflux (Supplemental table 1). Therefore, high efflux might compromise cellular exposures
20
21 achieved by both PROTACs. We reasoned that blocking multidrug efflux pumps (such as the
22
23 Multidrug-Resistance-Protein 1, PGP) might boost the potency and efficacy of both PROTACs
24
25 in cell lines with a large discrepancy between biochemical and intracellular activity.
26
27 Cyclosporine A (CsnA) has been described as a substrate of several drug transporters including
28
29 PGP⁴⁴ and can therefore be used to saturate these transporters at high concentrations.
30
31 Consequently, we assessed PTK2 degradation by both PROTACs upon addition of CsnA to
32
33 saturate drug transport in Hep3B2.1-7 (Figure 6A and B). Indeed, we observed a comparable
34
35 shift in the potency of PTK2 degradation for both PROTACs (Table 2), consistent with efflux
36
37 contributing to their reduced degradation efficacy in this cell line. Of note, CsnA only had a
38
39 minor effect on PTK2 levels (Figure 6C).

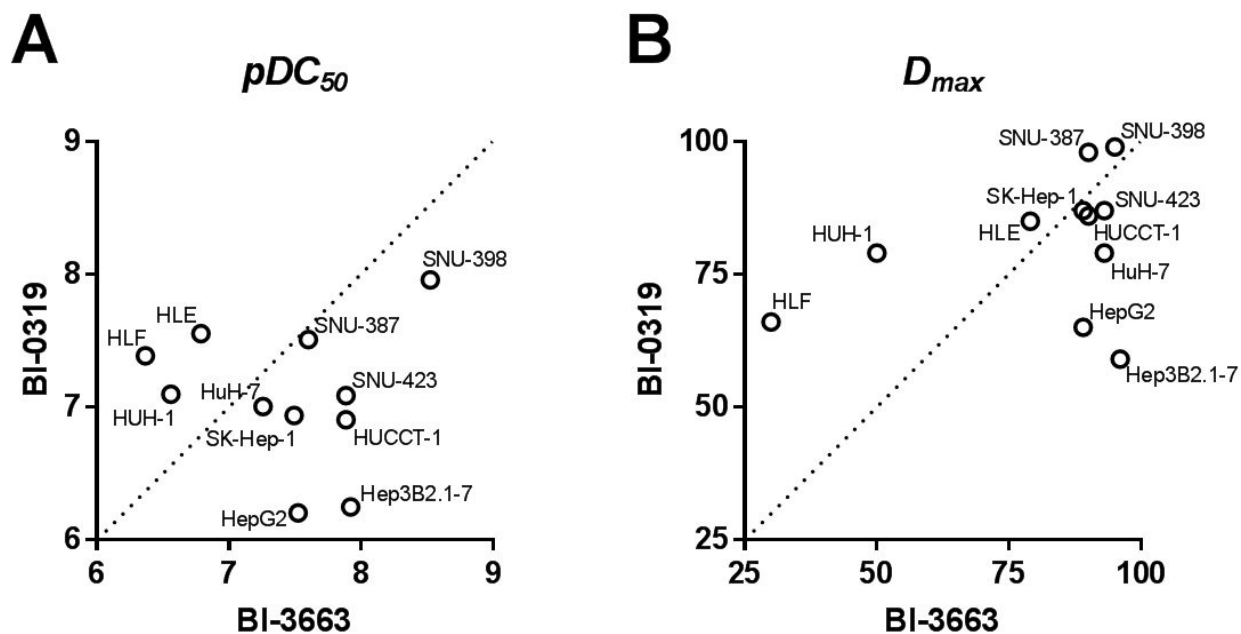

Figure 5. Cumulative analysis of half-maximal effective concentrations (DC_{50} , A) and maximal degree of PTK2 degradation (D_{max} , B) achieved by BI-0319 or BI-3663. pDC_{50} and D_{max} at 18 h were determined as indicated in supplemental figures 2 and 3.

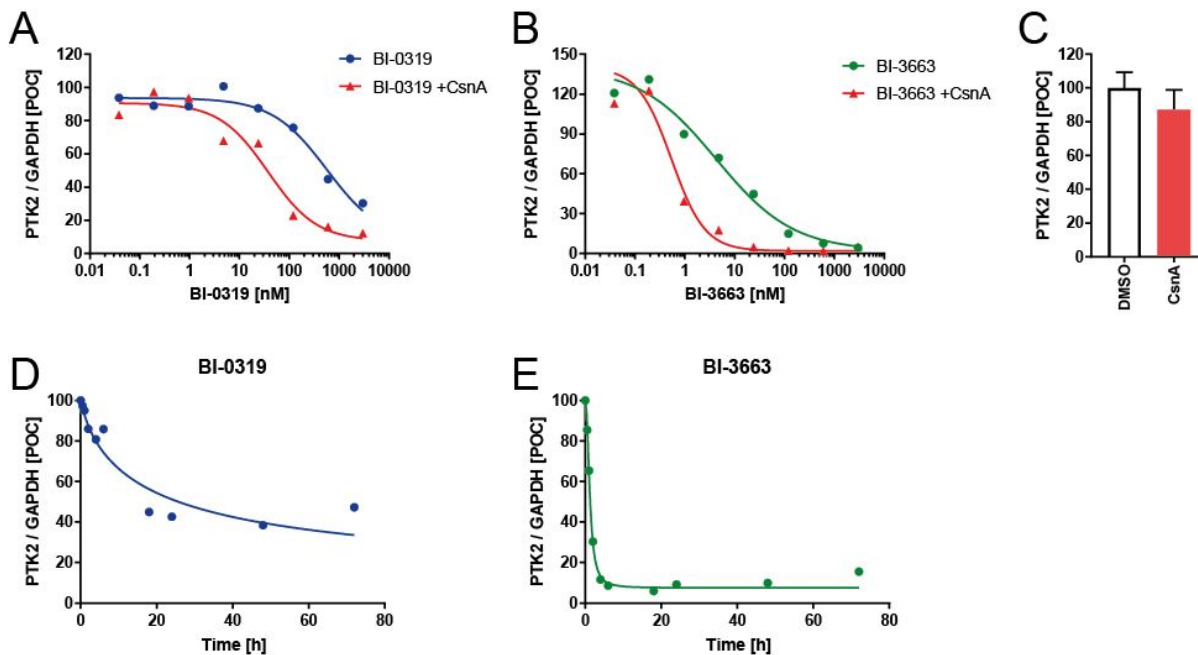

Figure 6. Analysis of PTK2 degradation in Hep3B2.1-7 cells. A) cells were treated with the indicated concentrations of BI-0319 for 18 h in presence (red triangles) or absence (blue circles) of 10 μ M cyclosporine A (CsnA). B) cells were treated for 18 h with the indicated concentrations of BI-3663 in presence (red triangles) or absence (green circles) of 10 μ M CsnA. C) cells were treated with 10 μ M CsnA for 18 h. D) Time course analysis of PTK2 levels in cells treated with 3 μ M BI-0319. E) Time course analysis of PTK2 levels in cells treated with 3 μ M BI-3663. Values state PTK2 protein levels normalized to GAPDH relative to DMSO (or CsnA only) controls.

Table 2. PTK2 degradation data of BI-3663 and BI-0319 in A549 and Hep3B2.1-7 cells.

	A549, 18 h*		Hep3B2.1-7, 18 h *		Hep3B2.1-7, 18 h * + 10 μ M CsnA	
	pDC ₅₀	D _{max} [%]	pDC ₅₀	D _{max} [%]	pDC ₅₀	D _{max} [%]
6 (BI- 3663)	7.6 \pm 0.1	95 \pm 4	7.9	96	9.0	94
8 (BI -0319)	6.7 \pm 0.4	80 \pm 9	6.2	59	7.4	88

* Degradation activity is reported as concentration needed to achieve 50 % PTK2 protein degradation (pDC₅₀ \pm STDEV) and maximal achievable protein degradation (D_{max}) relative to DMSO.

PROTACs **6** and **8** differ considerably with respect to their cellular degradation rate in Hep3B2.1-7 cells. The CRBN-based PROTAC **6** achieved complete degradation of PTK2 after five hours whereas the VHL-based PROTAC **8** achieved maximal degradation only after 20 hours (Figure 6D and E). Of note, the CRBN-based PROTAC **6** was considerably less stable in cell assay buffer containing 10% FCS (M+18 and +32 observed) than the VHL-based PROTAC **8** (Supplemental Table 1). PROTAC **6** was found to be stable as a solid and in DMSO stock solution (>3 month, data not shown). Despite this previously reported instability of CRBN based PROTACs⁴⁵ PROTAC **6** as well as PROTAC **8** showed comparable maximal degradation of PTK2 after 18 h and 72h days incubation (Supplemental figure 6). Taken together, this indicates that the both PROTACs **6** and **8** are suitable probes to further study the role of PTK2 in a broad range of tumour cell lines.

1
2
3 Reasoning that additional targeting of the scaffolding functions of PTK2 by PROTAC-
4 mediated degradation might result in enhanced efficacy as compared to inhibition of its kinase
5 activity, we next tested the effect of PROTAC-mediated PTK2 degradation on proliferation of
6 the same HCC cell lines. Surprisingly, efficient depletion of PTK2 by both PROTACs (Table 3
7 and Supplemental figures 2 and 3) did not affect proliferation of the tested cell lines more
8 severely than the PTK2 inhibitor BI-4464 in standard culture conditions or in anchorage-
9 independent growth assays (Table 3, Supplemental figures 4 and 5). Notably, sensitivity to
10 genetic depletion of PTK2 has been described for several of the tested cell lines (Supplemental
11 table 4). One explanation may be that effects on proliferation may require long-term depletion of
12 PTK2. To further address this, we treated cell lines with reported high sensitivity to genetic
13 depletion of PTK2^{36, 46} (Supplemental table 4) for 21 days with either PROTAC **6** (BI-3663) or **8**
14 (BI-0319) or the PTK2 inhibitor **1** (BI-4464). Despite the effective depletion of PTK2 even after
15 21 days, we did not observe any pronounced anti-proliferative effects for any of the tested cell
16 lines (Supplemental figure 6). Notably, CRISPR-based genetic validation in cultured HuH-1
17 cells also resulted in a weak dependency on PTK2 (Supplemental figure 7). Taken together, these
18 data questions the scaffolding function of PTK2 being required for *in vitro* proliferation of the
19 tested cell lines beyond the effect of inhibition of its kinase activity. Nevertheless, our
20 observations indicate that both probes can be used to effectively reduce PTK2 protein levels in
21 long term experiments in cultured cells.

Conclusion

We describe the development of two highly selective and functional PROTACs to degrade the PTK2 protein, a kinase of significant relevance to cancer research, in particular, in the area of hepatocellular carcinoma. Structure-guided conjugation of a highly selective PTK2 inhibitor BI-4464 to either a CRBN or VHL ligand via polyethylene glycol linkers led to the selective PTK2 degraders BI-0319 and BI-3663, respectively, using orthogonal E3 ligase binders. Both PROTACs were characterized with respect to *in vitro* PTK2 engagement, ligase dependence

1
2
3 selectivity (kinase inhibition as well as whole cell proteome) and degradation efficacy (DC_{50} and
4
5 D_{max}) in twelve cell lines (one lung cancer and eleven hepatocellular carcinoma cell lines). Both
6
7 PROTACs are highly selective E3 ligase-dependent PTK2 degraders and show overall
8
9 comparable potencies and efficacies of PTK2 degradation in the 12 cell tested lines. Whereas
10
11 PTK2 levels in cell lines such as SNU-398 were equally sensitive to treatment with both
12
13 PROTACs, other cell lines, such as Hep3B2.1-7 exhibited a more than ten-fold difference in
14
15 cellular potency. This difference in degradation efficacy in Hep3B2.1-7 cells was associated with
16
17 a higher degradation rate of BI-3663. Despite the efficient depletion of PTK2, treatment with
18
19 either PROTAC did not affect proliferation of the tested cell lines in either short or long term
20
21 assays in vitro (6 vs 21 days) beyond the effect achieved by a PTK2 kinase inhibitor. Taken
22
23 together, these data suggest that PROTACs **6** (BI-3663) and **8** (BI-0319) mediated PTK2
24
25 depletion is likely insufficient to affect proliferation in vitro under the conditions tested beyond
26
27 the effect of inhibition of its kinase activity. Nevertheless, both probes provide valuable tools to
28
29 effectively reduce PTK2 protein levels in experimental conditions that might be better suited to
30
31 reveal and differentiate between kinase- dependent and -independent functions of PTK2. BI-
32
33 3663, BI-0319 and its inactive control BI-4206 will be made available to all scientists via our
34
35 open innovation portal [opnMe](#).

EXPERIMENTAL SECTION

Chemistry. Synthesis. Unless otherwise indicated, all reactions were carried out in standard commercially available glassware using standard synthetic chemistry methods. Air-sensitive and moisture-sensitive reactions were performed under an atmosphere of dry nitrogen or argon with dried glassware. Commercial starting materials were used without further purification. Solvents used for reactions were of commercial “dry”- or “extra-dry” or “analytical” grade. All other solvents used were reagent grade.

The thin layer chromatography is carried out on ready-made silica gel 60 TLC plates on glass (with fluorescence indicator F-254) made by Merck. The preparative high pressure chromatography (RP-HPLC) is carried out on Gilson systems with columns made by Waters (names: Sunfire™ Prep C18, OBD™ 10 μm, 50x150 mm or XBridge™ Prep C18, OBD™ 10 μm, 50x150 mm) and YMC (names: Actus-Triart Prep C18, 5 μm, 30x50 mm). Different gradients of MeCN/H₂O are used to elute the compounds, for acidic conditions 0.1 % HCOOH is added to the water. For the chromatography under basic conditions the water is made alkaline as follows: 5 mL NH₄HCO₃ solution (158 g in 1 L H₂O) and 2 mL NH₃ (28 % in H₂O) are replenished to 1 L with H₂O.

All compounds had a purity >95% according to HPLC and NMR analysis acquired with the systems and parameters stated in the following. HPLC samples were analyzed on an Agilent 1200 series LC system coupled with an Agilent 6140 mass spectrometer. Purity was determined via UV detection with a bandwidth of 170nm in the range from 230-400nm. LC parameters were as follows: Waters Xbridge C18 column, 2.5μm particle size, 2.1 x 20mm. Total run time 3.1 minutes, flow 1ml/min, column temperature 60°C and 5μl injections. Solvent A (20mM

1
2
3 NH₄HCO₃/ NH₃ pH 9), solvent B (MS grade acetonitrile). Start 10% B, gradient 10% - 95% B
4
5 from 0.0 - 1.5min, 95% B from 1.5 - 2.0min, gradient 95% - 10% B from 2.0 – 2.1min.
6
7

8
9 NMR experiments were recorded on a Bruker Avance HD 500 MHz spectrometer equipped
10
11 with a TCI cryoprobe at 298 K. Samples were dissolved in 600 μL DMSO-d₆ and TMS was
12
13 added as an internal standard. 1D ¹H spectra were acquired with 30° excitation pulses and an
14
15 interpulse delay of 4.2 sec with 64k data points and 20 ppm sweep width. 1D ¹³C spectra were
16
17 acquired with broadband composite pulse decoupling (WALTZ16) and an interpulse delay of 3.3
18
19 sec with 64 k data points and a sweep width of 240 ppm. Processing and analysis of 1D spectra
20
21 was performed with Bruker Topspin 3.2 software. No zero filling was performed and spectra
22
23 were manually integrated after automatic baseline correction. Chemical shifts are reported in
24
25 ppm on the δ scale.
26
27
28
29

30
31 HSQC spectra were recorded on all samples to aid the interpretation of the data and to identify
32
33 signals hidden underneath solvent peaks. Spectra were acquired with sweep widths obtained by
34
35 automatic sweep width detection from 1D reference spectra in the direct dimension with 1k
36
37 datapoints and with 210 ppm, and 256 datapoints in the indirect dimension.

8 9 **Protein expression and purification.**

10 Human PTK2 (residues 411–689, UniProt accession number Q05397) with an N-terminal TEV
11 cleavage site was cloned into pDEST20 vector (Invitrogen). Expression in this vector results in a
12 fusion protein with a cleavable GST tag. Viral stocks were generated in the Bac-to-Bac system
13 (Invitrogen) and used to infect *Trichoplusia ni* (Hi5) cells (Invitrogen). Recombinant protein was
14 isolated from cell extracts by affinity chromatography over glutathione sepharose (GE
15 Healthcare) in batch mode. The GST-tag was removed by incubation with Ac-TEV protease
16 (ThermoFisher) on the resin, overnight at 4 °C. Cleaved protein was recovered, concentrated
17 (biomax 10, Merck) and finally purified by size exclusion chromatography on HiLoad Superdex
18 S75 (GE Healthcare). The protein was concentrated (biomax 10, Merck) to 5 mg/ml and stored
19 in 20 mM HEPES, 250 mM NaCl, 1 mM DTT, 1 mM EDTA, pH 6.7 at -80 °C.

34 35 **Crystallization of the PTK2 kinasedomain BI 4464 binary complex.**

36 Protein crystallization was done using the sitting drop method by incubating the protein with
37 1 mM BI 4464 (as 50 mM stock solution) and mixing 0.2 μ L of PTK2 (4.5 mg/mL in 25 mM
38 HEPES pH 6.7, 250 mM NaCl, 1 mM DTT, 1 mM EDTA) with 0.2 μ L of reservoir solution
39 (7 % PEG 1500, 100 mM SPG buffer pH 6.0) at 4 °C. Crystals grew as thin plates within a few
40 days to a final size of 150-200 μ m). Crystals were transferred to a cryo buffer (reservoir solution
41 with 15 % ethylene glycol) and frozen in liquid nitrogen. Data were collected at the SLS beam
42 line X06DA (Swiss Light Source, Paul Scherrer Institute) at a wavelength of 0.91 Å using the
43 PILATUS 2M detector. The crystals belonged to space group $P2_12_12$ with 1 monomer per
44 asymmetric unit. Images were processed with XDS⁴⁸. The structures were solved by molecular

23

24 **Cell culture.**

25
26
27 Cell lines were obtained through ATCC or JCRB, verified for identity by satellite repeat
28
29 analysis, tested for mycoplasma contamination at regular intervals and cultured in the specified
30
31 media in a humidified cell incubator at 37 °C and 5 % CO₂. DMEM was obtained from Lonza
32
33 (product code BE12-604F), EMEM from ATCC (product code 30-2003), IMDM from Thermo
34
35 Fisher (product code 12440053), RPMI-1640 from Thermo Fisher (product code A1049101).
36
37 The following cell lines (product codes and culture media in parentheses) were used for the
38
39 described experiments: SNU-387 (CRL-2237, RPMI-1640 plus 10 % heat inactivated FCS),
40
41 HUH-1 (JCRB0199, DMEM plus 10 % FCS), Hep3B2.1-7 (HB-8064, EMEM plus 10 % FCS),
42
43 HepG2 (HB-8065, EMEM plus 10 % FCS plus Glutamax), SK-Hep-1 HLF (JCRB0404 DMEM
44
45 plus 10 % FCS), SNU-398 (CRL-2233, RPMI1640 plus 10 % FCS), HUCCT1 (JCRB0425,
46
47 RPMI-1640 plus 10 % FCS), HLE (JCRB0405, DMEM plus 10 % FCS), HuH-7 (JCRB0403
48
49 DMEM plus 10 % FCS), SNU-423 (CRL-2238, RPMI-1640 plus 10 % FCS), A549 (CCL-185,

6
7

8 **Protein degradation assays.**

9
10 To quantify the effects of compounds on PTK2 protein levels, cells were seeded at a density of
11
12 125.000 cells in 0.75 mL of culture medium 24-well plates and allowed to attach for 6-8 hours.
13
14 Subsequently, compounds were added to the cells at logarithmic dose series using the HP Digital
15
16 Dispenser D300 (Tecan), normalizing for added DMSO. After compound addition, cells were
17
18 incubated for 18 h or the specified time intervals at 37 °C. Cells were washed with cold PBS and
19
20 lysed by immediate freezing in 100 µL RIPA buffer (Sigma product code R0278) supplemented
21
22 with 1:100 HALT Phosphatase-Protease Inhibitors (Thermo product code 1861281) at -80 °C.
23
24 After thawing, samples were transferred into V-bottom 96-well plates, cellular debris was
25
26 sedimented at 4000 rpm (Eppendorf centrifuge 5810R, rotor A-4-81). 90 µL of the supernatant
27
28 were transferred into a new 96-well plate and analyzed using a Wes capillary electrophoresis
29
30 instrument (Proteinsimple) using PTK2 antibody (Cell Signaling product code 13009) at a
31
32 dilution of 1:50 or PDE6D antibody (Abcam product code ab5665) at a dilution of 1:25 and
33
34 GAPDH antibody (Abcam product code ab9485) at a dilution of 1:2000 for normalization.
35
36
37
38
39
40

41 **Proliferation assays.**

42
43 *Standard proliferation assay.* To test the effect of PTK2 PROTACs on proliferation, cells were
44
45 seeded at 1000 cells per well (2500 cells per well for suspension cell lines) in 100 µL growth
46
47 medium in a white bottom opaque 96-well plate and allowed to grow over night. To obtain
48
49 starting densities, a set of cells seeded in parallel were lysed and measured using 100 µL
50
51 CellTiter-Glo luminescent cell viability reagent (Promega product code G7570) per well as per
52
53 manufacturer's recommendation. Compounds were added to the cells at logarithmic dose series
54
55
56
57
58
59
60

1
2
3 using the HP Digital Dispenser D300 (Tecan), normalizing for added DMSO. Doxorubicin
4 (Sigma product code D1515) was used as a positive control. Upon compound addition, cells
5
6 (Sigma product code D1515) was used as a positive control. Upon compound addition, cells
7
8 were incubated for six days and viability measured CellTiterGlow reagent as described above.
9
10 Results are stated as mean and standard deviation of triplicate experiments.
11

12
13 *Anchorage independent growth assays.* Cells were seeded in 0.3 % agarose (Gibco product
14 code 18300-012) containing cultivation medium (60 μ L) on top of a bottom layer composed of
15
16 1.2 % agarose in cultivation medium (90 μ L) in 96-well plates. Upon solidification of the cell
17
18 layer, the culture was overlaid with 50 μ L cultivation medium and compounds were added as
19
20 indicated above. Cultures were allowed to grow for 7-14 days, stained with alamar blue reagent
21
22 (Thermo Fisher product code DAL1025) and measured using a fluorescence plate reader (Wallac
23
24 Victor 1420, 544 nm excitation, 590 nm emission, 0.2 s).
25
26
27
28
29

30
31 *Long-term proliferation assay.* Cells were inoculated at a density of 250,000 cells in 1.5 mL
32
33 culture medium in 6 well plates. Compounds or DMSO were added, and every 3 to 4 days cells
34
35 were split to 250,000 cells. Upon splitting, fresh compound was added to keep the concentration
36
37 constant. Split rates were recorded and multiplied to derive cumulative cell counts which were
38
39 converted into population doublings (n) using the formula $n = (\log(N_x) - \log(N_0)) / \log 2$ with N_x
40
41 indicating the cumulative cell count at time-point x and N_0 the initial seeding cell count.
42
43
44

45 **MS proteomics.**

46
47 *Sample preparation.* A549 cells were seeded at 5×10^6 cells/mL in a 10 cm plate 18 h before
48
49 treatment. Cells were treated with 0.1% DMSO as vehicle control, 3 μ M of either active
50
51 PROTAC **6** or **8**, and 3 μ M of *cis*VHL **11** as negative control. Cells were incubated at 37 °C and
52
53 5 % CO₂ for 18 h before harvesting. Cells were washed twice with DPBS (Gibco) and lysed with
54
55
56
57
58
59
60

1
2
3 0.5 mL of 100 mM Tris pH 8.0, 4 % (w/v) SDS, supplemented with cOmplete™ Mini EDTA-
4 free Protease Inhibitor Cocktail (Roche). Lysates were sonicated (2 x 10 s) and centrifuged at
5
6 14,000 rpm for 20 min at 4 °C. The supernatant fraction of the cell extract was collected and
7
8 protein concentration was quantified by BCA assay (Thermo Fisher Scientific). Further sample
9
10 processing, digestion, desalting, TMT 10-plex isobaric labelling were performed as previously
11
12 described.⁵ After labelling, the peptides from the 9 samples were pooled together in equal
13
14 proportion. The pooled sample was fractionated using high pH reverse-phase chromatography on
15
16 an XBridge peptide BEH column (130 Å, 3.5 µm, 2.1 × 150 mm, Waters) on an Ultimate 3000
17
18 HPLC system (Thermo Scientific/Dionex). A mixture of Buffer A (10 mM ammonium formate
19
20 in water, pH 9) and B (10 mM ammonium formate in 90 % CH₃CN, pH 9) was used over a
21
22 linear gradient of 5 % to 60 % buffer B over 60 min at a flow rate of 200 µL/min. The peptides
23
24 eluted from the column were collected in 80 fractions before concatenation into 20 fractions
25
26 based on the UV signal of each fraction. All the fractions were dried in a Genevac EZ-2
27
28 concentrator and resuspended in 1 % formic acid for MS analysis.
29
30
31
32
33
34

35 *nLC-MS/MS analysis.* The fractions were analyzed sequentially on a Q Exactive HF-X Hybrid
36
37 Quadrupole-Orbitrap Mass Spectrometer (Thermo Scientific) coupled to an UltiMate 3000
38
39 RSLCnano UHPLC system (Thermo Scientific) and EasySpray column (75 µm × 50 cm,
40
41 PepMap RSLC C18 column, 2 µm, 100 Å, Thermo Scientific). A mix of buffer A (0.1 % formic
42
43 acid in H₂O) and B (0.08 % formic acid in 80 % CH₃CN) was used over a linear gradient from
44
45 5 % to 35 % buffer B over 125 min using a flow rate of 300 nL/min. The column temperature
46
47 was set at 50 °C. The mass Spectrometer was operated in data dependent mode with a single MS
48
49 survey scan from 335-1,600 *m/z* followed by 15 sequential *m/z* dependent MS₂ scans. The 15
50
51 most intense precursor ions were sequentially fragmented by higher energy collision dissociation
52
53
54
55
56
57
58
59
60

1
2
3 (HCD). The MS1 isolation window was set to 0.7 m/z and the resolution set at 120,000. MS2
4 resolution was set at 45,000. The AGC targets for MS1 and MS2 were set at $3e^6$ ions and $1e^5$
5 ions, respectively. The normalized collision energy was set at 32 %. The maximum ion injection
6 times for MS1 and MS2 were set at 50 ms and 200 ms, respectively.
7
8
9
10
11

12 *Peptide and protein identification and quantification.* The raw MS data files for all 20 fractions
13 were merged and searched against the Uniprot-sprot-Human-Canonical database by Maxquant
14 software 1.6.0.16 for protein identification and TMT reporter ion quantitation. The
15 identifications were based on the following criteria: enzyme used Trypsin/P; maximum number
16 of missed cleavages equal to two; precursor mass tolerance equal to 10 p.p.m.; fragment mass
17 tolerance equal to 20 p.p.m.; variable modifications: Oxidation (M), Acetyl (N-term),
18 Deamidation (NQ), Gln \rightarrow pyro-Glu (Q N-term); fixed modifications: Carbamidomethyl (C).
19 The data was filtered by applying a 1 % false discovery rate followed by exclusion of proteins
20 with less than two unique peptides. Quantified proteins were filtered if the absolute fold-change
21 difference between the three DMSO replicates was ≥ 1.5 .

The manuscript was written through contributions of all authors. All authors have given approval to the final version of the manuscript.

FUNDING SOURCES

NOTES

While this manuscript was in advanced preparation selective VHL based PTK2 PROTACs were published by P. M. Cromm et al. J. Am. Chem. Soc., DOI: 10.1021/jacs.8b08008 as a manuscript just accepted, describing a VHL-based degrader (PROTAC-3) with chemical structure different from BI-0319.

ACKNOWLEDGMENT

We would like to thank Will Farnaby for coordination of the proteomics study, Moriz Mayer for coordinating the analytics, Gerlinde Flotzinger for PTK2 protein expression and purification, and Gabriele Glenndining and Susanne Mayer for their excellent logistics work for the collaboration between Boehringer Ingelheim and University of Dundee.
