We have fabricated a flexible membrane, consisting of SiO₂ nanofibres armoured with upconversion nanoparticles, exhibiting intense photoluminescence. These assemblies were subsequently grafted with molecular beacons to produce a biosensor suitable for the detection of specific microRNA and with applications in early cancer detection and point-of-care diagnosis.

MicroRNAs (miRNAs) dysfunction facilitates tumor growth, metastasis, angiogenesis, and immune evasion.^{1, 2} The detection of cancer-related miRNAs, which present in body fluids, has been well recognized as a potential strategy for non-invasive early cancer diagnosis.^{3, 4} Current approaches for miRNA detection fall into two main categories: biological testing methods (i.e. Northern blotting,⁵ quantitative RT-qPCR^{6, 7} and microarray assays^{8, 9}) and chemical methods (i.e. electrochemical, fluorescent and electro-chemiluminescent platforms¹⁰⁻¹²). Fluorescence-based sensors, driven by the fluorescence resonance energy transfer (FRET) mechanism, have attracted considerable attention.¹³⁻¹⁶ The FRET effect is related to the distance between the energy donor fluorophores and energy acceptor quenchers. In general, when the distance is below 10 nm, FRET occurs, and *vice versa*.

Upconversion luminescence nanomaterials have been explored for the construction of FRET-based miRNA detection biosensors owing to a number of intrinsic advantages, such as narrow emission peaks, long lifetime and superior photostability.¹⁷⁻²¹ Photoluminescence nanofibres, where

upconversion CaF₂ nanoparticles were incorporated within SiO₂ nanofibres via a particle electrospinning approach and subsequently grafted with miRNA capture probes, were investigated as a sensor for miRNA detection.²² In the presence of target miRNA, the FRET effect is triggered and emission profiles can be used to assess the concentration of target miRNA. However, this particular type of upconversion nanoparticle(UCNP)-embedded nanofibres are poorly suited for clinical translation for miRNA detection due to their mechanical brittleness and limited sensitivity and selectivity. In contrast, UCNP-incorporated polymeric nanofibres have been reported as a type of alternative sensor.²³⁻²⁵ However, the severe quenching by organic groups results in low intensity emission and poor sensitivity in biomarker detection. Therefore, there is a clear demand for an alternative technology based on flexible nanofibres with intense upconversion luminescence for biomarker detection.

Inspired by the flexible SiO₂ nanofibres achieved,²⁶ we hereby report the design and synthesis of a flexible membrane, consisting of SiO₂ nanofibres 'armoured' with upconversion nanoparticles (SiO₂@UCNP) for miRNA detection. (Fig 1) In this system, NaYF₄:Yb,Er upconversion nanoparticles were assembled at the surface of SiO₂ nanofibres (SiO₂@UCNP) via solvothermal growth. Carboxyl molecular beacons (MBs) with a Black Hole Quencher 3 (BHQ3) quencher were covalently

Fig. 1 Schematic illustration of the synthesis of SiO₂@UCNP-MB biosensor and miRNA detection.

Electronic Supplementary Information (ESI) available: SEM image and diameter distribution of SiO₂ nanofibres. TG analysis of electrospun PVA/SiO₂ nanofibres. Elemental mapping of SiO₂@UCNP nanofibres. TEM image and XRD pattern of NaYF₄:Yb,Er nanoparticles. Upconversion luminescence spectra of SiO₂@UCNP fibres and UCNP. SEM and TEM images of electrospun NaYF₄:Yb,Er nanoparticles embedded SiO₂ nanofibres. See DOI: 10.1039/x0xx00000x

grafted onto SiO₂@UCNP nanofibres. The red-light emission at 660 nm was quenched after MB immobilization. When the target miRNA presents, complementary co-hybridization between target and MB's loop sequence occurs and opens the hairpin structure, and the red-light emission at 660 nm recovered, resulting in the variation of intensity ratio I_{660}/I_{550} (spectrum at 660 nm to that at 550 nm).

Flexible SiO₂ fibres were synthesized by electrospinning based on modified protocol reported previously.²⁶ After calcination at 800 °C for 3 hours, SiO₂ nanofibres with smooth surface morphology and random porous structure, were prepared. (Fig. S1) No clear weight loss was observed when the samples were heated at above 800 °C, indicating the complete removal of PVA and the thermal stability of SiO₂ membrane (Fig. S2).²⁷ The inset optical micrograph shows a SiO₂ membrane wrapped around a test tube, demonstrating its flexibility (Fig. 2a).

After solvothermal growth of UCNP, the average diameter of SiO₂ nanofibres increased from ~380 nm to ~450 nm due to the assembly of UCNPs at the surfaces (Fig. 2a). TEM images show a uniform array of well-anchored UCNPs with a diameter of 30-50 nm (Fig. 2b). The high-resolution TEM (HRTEM) image reveals that the UCNPs comprised single crystals with clear lattice fringes with a d-spacing of 0.31 nm, corresponding to the (111) planes of the cubic NaYF₄:Yb,Er crystal (Fig. 2c). The XRD pattern of SiO₂@UCNP nanofibres shows a broad peak from 15° to 35° which is ascribed to amorphous SiO₂. All diffraction peaks on the trace match well with the characteristic pattern for α -

NaYF₄:Yb,Er phase (JCPDS-77-2042), indicating an assembly of highly crystalline UCNPs on the surface of SiO₂ nanofibres. (Fig. 1d) The results of EDS mapping confirm the uniform and dense arrangement of UCNPs on the surface of nanofibres (Fig. S3). It was also observed that prolonged solvothermal time or reduced content of SiO₂ fibres during the synthesis may induce an assembly of increased content of UCNPs at the fibre surface (Fig S4).

For the formation of nanocrystals at the fibre surface, surfactants such as PVP, PEI are often used to guide the growth of the nanocrystals.²⁸ In this study, PEI was chosen as the surfactant owing to its positive charge. Initially, a Y-PEI complex is formed after inducing the Ln³⁺ solution. Subsequently, NaYF₄ nucleation occurs rapidly by the reaction of a mixture containing Y-PEI, NaCl and NH₄F, producing a white colloid solution (Fig. 2e). SiO₂ nanofibres are negatively charged due to the high content of Si-OH groups present at the surface. When immersing SiO₂ nanofibres in NaYF₄:Yb,Er precursor solution, NaYF₄ nuclei are adsorbed on the surface of the SiO₂ nanofibres via electrostatic attraction. NaYF₄ nucleus grow progressively to form NaYF₄ nanocrystals as the solvothermal process evolved. The Zeta potential consequently increases from -54 mV for SiO₂ nanofibres to ~56 mV of SiO₂@UCNP nanofibres, confirming the existence of the UCNPs attached with PEI groups (Fig. 3b). This model of a nucleation-adsorption-growth mechanism can be applied to explain the preparation of many SiO₂@nanocrystal complex nanofibres such as SiO₂@MnO₂, SiO₂@LDH and SiO₂@NiFeO₄ nanofibres.²⁹⁻³¹

Intense upconversion luminescence of biosensors is a crucial characteristic for ensuring the sensitivity and selectivity of miRNA detection, especially in FRET based platforms. In this study, under irradiation using a 980 nm laser, the SiO₂@UCNP nanofibres exhibited two main upconversion luminescence (UCL) emissions. The green emission (550 nm) was induced by (²H_{11/2}, ⁴S_{3/2}) → ⁴I_{15/2} transition, and the red emission was attributed to ⁴F_{9/2} → ⁴I_{15/2} transition, which is similar to that of NaYF₄:Yb,Er nanoparticles. (Fig. 2f) Notably, the UCL intensity of SiO₂@UCNP nanofibres was about 30-fold higher than that of NaYF₄:Yb,Er nanoparticles embedded SiO₂ nanofibres fabricated following the protocols reported previously³², and comparable to that of pure NaYF₄:Yb,Er nanoparticles (Fig S5 & S6). The enhanced UCL intensity of SiO₂@UCNP nanofibres was attributed to the high density of UCNPs presented at the fibre surface and highly suppressed quenching effect by SiO₂ matrix. In contrast, for the UCL SiO₂ nanofibres reported previously³², UCNPs are conventionally incorporated via a particle electrospinning method. The loading efficiency is limited because instability occurs when excessive particles are incorporated during electrospinning. Moreover, UCL emission of UCNP embedded in SiO₂ matrix is dramatically quenched by SiO₂ matrix. The 'armouring' of flexible SiO₂ nanofibres with UCNPs at the outer surface in this study has enabled the construction of UCL nanofibres with unique structural, mechanical and optical characteristics for biomarker detection and potentially localized photodynamic therapy.

Subsequently, carboxyl group-modified molecular beacons were immobilized on the surface of SiO₂@UCNP nanofibres via

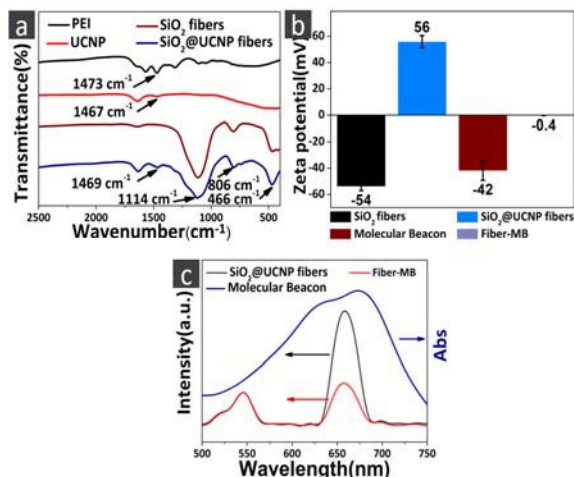

Fig. 3 (a) FTIR spectra of PEI, UCNP, SiO₂ fibres and SiO₂@UCNP fibres; (b) Zeta potentials of SiO₂ fibres, SiO₂@UCNP fibres, molecular beacons and SiO₂@UCNP-MB composite; (c) Upconversion luminescence spectra of SiO₂@UCNP fibres before and after molecular beacon grafting, and UV-vis spectrum of molecular beacons.

an amide reaction. As shown in Fig. 3a, the FTIR spectrum of the SiO₂ nanofibres reveals typical SiO₂ absorption bands at ~466 cm⁻¹ for Si-O-Si bending vibration, at ~806 cm⁻¹ for Si-O-Si symmetric stretching vibration and at ~1114 cm⁻¹ for Si-O-Si asymmetric stretching vibration. Owing to UCNP assembly, a new peak at ~1470 cm⁻¹, which is assigned to N-H bending of secondary amines and -CH₂ scissoring vibrations of PEI, appears in the FTIR spectrum of SiO₂@UCNP nanofibres.³³ Accordingly, the increase of Zeta potential also confirms the presence of PEI. (Fig. 3b)

The UV-vis absorption of the molecular beacon shows a broad band at ~660 nm due to the BHQ3 quencher (Fig. 3c). After MB immobilization, emission of SiO₂@UCNP nanofibres at 660 nm was significantly quenched, resulting in a decrease in the intensity ratio of red emission to green light from 3.5 to 1.1. The conjugation of MB was further confirmed by the negative zeta potential of SiO₂@UCNP-MB composite resulting from the presence of negatively charged molecular beacon.

The FRET effect is closely related to the distance between the energy donor (UCNP on SiO₂@UCNP nanofibres) and acceptor (BHQ3). In general, the FRET effect occurs when the distance between the energy donor and acceptor is less than 10 nm. After molecular beacon immobilization, BHQ3 and UCNP were brought into close proximity, and the FRET phenomenon occurred, as reflected in Fig. 3c. For the miRNA detection examination, a membrane consisting of SiO₂@UCNP-MB fibres was immersed in a test tube containing 2 mL deionized water. When target miRNA solutions with known concentrations were added, the intensity ratio of I₆₆₀ (intensity at 660nm) to I₅₅₀ (intensity at 550 nm) recovered to 3.45 when the concentration of miRNA-21 reached 500 nM, indicating the successful restoration of red light emission (Figure 4a). The relationship between I₆₆₀/I₅₅₀ (intensity ratio of red light to green light of SiO₂@UCNP-MB composite in the presence and absence of

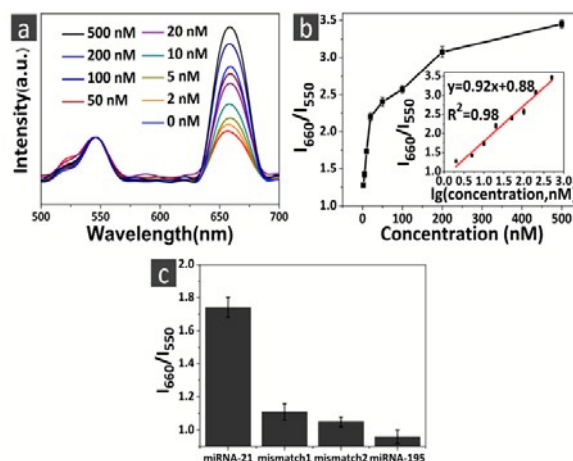

Fig. 4 (a) Upconversion luminescence spectra of SiO₂@UCNP-MB biosensor at different concentrations of miRNA-21; (b) relationship between the intensity ratio I₆₆₀/I₅₅₀ and the concentration of miRNA-21; (c) specific detection of miRNA-21, miRNA-21 with single base mismatch, miRNA-21 with three bases mismatches and miRNA-195.

target miRNA) and concentration of target miRNA (miRNA-21) is shown in Fig. 4b. I₆₆₀/I₅₅₀ increased with the addition of target miRNA and varied with the concentration of miRNA-21 in a linear manner. The limit of detection was ~2 nM in DI water. This phenomenon is attributed to the co-hybridization which occurred between the target miRNA and the molecular beacon's loop sequence. When the target miRNA is present, the hairpin structure is opened, and the quencher and UCNP are separated, enabling the recovery of emission of UCNP at 660 nm upon excitation. The selective detection of miRNA in a biological condition was verified using 10%vol fetal bovine serum. The I₆₆₀/I₅₅₀ ratio presents in a linear relationship with miRNA-21 concentration when the miRNA-21 concentration varies from 50 nM to 500 nM. (Fig. S7 a&b) It is noted that the detection performance was weakened due to the interaction between protein molecules and Fibre-MB biosensor.³⁴

A unique advantage of MBs-based biosensors is the high specificity due to the intrinsic hairpin structure.³⁵⁻³⁶ Carcinogenesis is generally accompanied with a series of DNA mutations, and many miRNA family members only have one base mismatch difference. Thus, discriminating similar miRNA sequences is vital for cancer detection. To validate the specificity of SiO₂@UCNP-MB sensor, miRNA-21, miRNA-21

Table 1 Sequences of Molecular Beacons, miRNA-21, miRNA-195, mismatch1 and mismatch2.

Oligonucleotide name	Sequences (5'-3')
Molecular beacon	COOH-AGCGTCAACATCAGTCTGATAAGCTACGCT-BHQ3
miRNA-21	UAGCUUAUCAGACUGAUGUUGA
Mismatch 1	UAGCUUAUCCGACUGAUGUUGA
Mismatch 2	UAGCUUAUACUACUGAUGUUGA
miRNA-195	UAGCAGCACAGAAUUAUUGGC

with single-base mismatch and three-base mismatch and miRNA-195, listed in Table 1, were synthesized and used for further test. As shown in Figure 4c, I_{660}/I_{550} ratio reaches 1.74 in the presence of 10 nM of miRNA-21, while this ratio maintains at 1.1 and 1.0 when 10 nM of miRNA-21 with single-base and three-base mismatch were added, respectively. In addition, the presence of miRNA-195 hardly induces variation of the I_{660}/I_{550} ratio, indicating detection specificity of the SiO_2 @UCNP-MB fibres. In a fetal bovine condition, the biosensor presented certain discrimination among miRNA-21, one-base and three-base mismatched miRNA-21 and miRNA-195, demonstrating its detection specificity in biological environment. (Fig. S7 c&d)

In summary, $\text{NaYF}_4\text{:Yb,Er}$ nanoparticles were assembled on the surface of flexible SiO_2 nanofibre following a nucleation-adsorption-growth mechanism. The 'armoured' fibres exhibit high intensity of upconversion luminescence at 550 nm and 660 nm owing to high content of UCNPs incorporated and suppressed quenching by amorphous SiO_2 matrix. When grafted with molecular beacons, the FRET effect is triggered and the emission at 660 nm is significantly reduced by the quencher in the MB molecules. In the presence of target miRNA, the complementary co-hybridization between target sequence and the loop sequence of the molecular beacon opens the hairpin structure and the emission at 660 nm recovered, enabling the quantitative detection of target miRNA concentration. The limit of detection reaches ~ 2 nM while the specificity is ensured. Comparing to current photoluminescence detection schemes, this membrane of armoured nanofibres, presenting superior UCL, mechanical flexibility for practical operation and unique detection properties, is therefore anticipated to offer considerable potential as a biosensor in early cancer diagnosis and therapy.
