Abstract

This paper proposes a new calculus for expressing the behaviour of object-oriented systems. The semantics of the calculus is given in terms of operators from computational category theory. The calculus aims to span the gulf between abstract specification and concrete implementation of object-oriented systems using mathematically verifiable properties and transformations. The calculus is compositional and can be used to express the behaviour of partial system views. The calculus is used to specify, analyse and refine a simple case study.

1 Introduction

In [Gog75], [Ehr91] and [Gog90] Goguen et al. propose an abstract model of object systems based on standard constructions in Category Theory. They show how to use the constructions to build systems but do not propose a calculus for expressing and reasoning about them. In [Cla99a], [Cla99b] and [Cla99c] a calculus is proposed for expressing object systems based on Goguen's work. The calculus was shown to support incremental system development based on features of Computational Category Theory [Ryd88]. The calculus does not have a formal semantics and therefore its link to the abstract object model is weak.

This paper develops a formal semantics for the λ_o-calculus. The semantics encodes the required categorical constructions as builtin operators and then uses them to express a number of features of object-oriented systems development including: (under-)specification; refinement; encapsulation; invariant properties.

This work contributes to the area of object-oriented systems development by providing a rigorous framework within which aspects of development can be defined and explored. In particular the λ_o-calculus aims to span the gulf between abstract specification and concrete implementation using mathematically verifiable refinement transformations. The λ_o-calculus can express partial views of a system and is therefore suitable as the basis for a semantics of UML [UML98] and as such can be seen as an extension of, or complimentary to, [Cla97] [Eva98] [Eva99] and [Lan98].

The builtin operators of the λ_o-calculus arise from Computational Category Theory. The reader is directed to [Bar90], [Ryd88] and [Gog89] for definitions of the appropriate constructs and to [Cla99a] for a discussion of how these constructs are used in the development of object-oriented systems.

This work differs from other approaches with similar aims. The Object Calculus [Bic97] uses similar categorical constructs but uses a logic rather than a λ-calculus to express models. Following Goguen, we propose that the behaviour of a system is a limit on a diagram of behaviours; diagrams are also used in [Ken99] [Ken97] where the aim is to express logical properties of data. Other calculi have been proposed as the basis for object-oriented systems, notably those defined in [Aba98]. The λ_o-calculus differs from other calculi in that it can express partial views of a system, incorporates non-determinism, solve constraints via equalizers and has a builtin notion of refinement via refinement morphisms.

The paper is structured as follows: section 2 gives an overview of the semantic model used for object-oriented systems; section 3 defines the λ_o-calculus used to express the model; section 4 defines a simple system requirements

that is used to demonstrate features of object-oriented system development using the λ_o-calculus in the rest of the paper; section 5 shows how a system invariant is verified; section 6 shows how mutual constraints can be achieved by composing sub-systems; section 7 shows how object-oriented encapsulation can be achieved using the refinement; finally sections 8 and 9 show how refinement achieves concrete data representation and an implementation in Java.

2   Behavioural Object-Oriented Model

Systems are constructed as a collection of objects. Each object is a separate computational system with its own state modified in response to handling messages. A message is a package of information sent from one object to another.

The computation performed when a message is handled by an object depends on the object's current state and causes the object to change state and produce output messages. If we observed an object over a period of time we would see a sequence of messages and state changes: $\ldots \sigma_1 \overset{(I_1, O_1)}{\longmapsto} \sigma_2 \overset{(I_2, O_2)}{\longmapsto} \sigma_3 \ldots$ where each σ_j is an object state, I_j are input messages, and O_j are output messages. Such a sequence is an *object calculation* and describes a single object in state σ_j receiving messages I_j causing a state change to σ_{j+1} and producing output messages O_j.

A message consists of a source object, a target object and some message data. The source and target objects are identified by their object identity tags. For a given object system, the data items which can be passed as messages will be defined for each type of target object. A message, whether input or output, is represented as (t_1, t_2, v) where t_1 identifies the source object, t_2 identifies the target object and v is the message data. Where any of the message components may be inferred from context they are elided.

Object systems are constructed from multiple objects interacting by passing messages. The state of an object system is a set of object states S. Computation in an object system occurs when the messages in set I are sent to the objects in S producing a new set of object states S' and a collection of output messages O: $\ldots \longmapsto S \overset{(I, O)}{\longmapsto} S' \longmapsto \ldots$ Object-oriented designs represent non-deterministic computational systems. Object calculations are represented as a *calculation graph* where the nodes of the graph are labelled with sets of states and the edges are labelled with pairs of input and output message sets.

Object system calculations can be transformed by graph homomorphisms. Such transformations can be used as the basis of system composition operations based on graph products and coproducts. Equalizers can be used to constructively find equivalence proofs expressed in terms of graph homomorphisms. The behaviour of a system is expressed as a limit on a diagram consisting of calculation graphs and graph homomorphisms. System properties can be expressed by adding the required behaviour to the diagram and then showing that the limit is preserved.

The rest of this paper uses these features as the semantic basis of a calculus for expressing, verifying and transforming object-oriented system designs.

3   The λ_o-Calculus

The λ_o-calculus is a notation for expressing object-oriented system designs. It is a standard normal order λ-calculus [Han94] [Plo75] extended with builtin operators [Lan64] for constructing behaviour functions in terms of behaviour products, coproducts, equalizers and morphisms.

The syntax of the λ_o-calculus is given in figure 1. The semantics of the basic calculus is given as a convertibility relation between terms in appendix A. All λ_o-terms have a type given by the type theory defined in appendix A. The following sugar e_1 **whererec** $v = e_2$ is translated as $(\lambda v.e_1)(\mu v.e_2)$. The following sugar **case** e_1 **of** $\ldots$ **else** e_2 **end** is translated as **case** e_1 **of** $\ldots$ $v \rightarrow e_2$ **end**.

3.1   Object Calculations and Morphisms

An *object calculation* is a sequence of object state transitions caused as a result of a collection of objects receiving messages, changing state and sending messages. Given an object with identity t, state v and behaviour e, if the object receives messages I, changes state and behaviour to v' and e', and produces output messages O then $e\{(t, v)\}I = (e'\{(t, v')\}, O)$.

e	$::=$		expressions
	v		variable
	$\mid \lambda v.e$		function
	$\mid ee$		application
	$\mid \mu v.e$		recursive definition
	$\mid (e, \ldots, e)$		tuple
	$\mid ce \ldots e$		structure
	$\mid \textbf{case } e \textbf{ of } p \to e; \ldots; p \to e \textbf{ end}$	selection
	$\mid (e, e)e$		object morphism

p	$::=$	patterns
	v	variable
	$\mid cp \ldots p$	structure
	$\mid (p, \ldots p)$	tuple

v	$::=$	values
	$\lambda v.e$	function
	$\mid ce \ldots e$	structure
	$\mid (e, \ldots, e)$	tuple
	$\mid n$	integer
	$\mid t$	tag

τ	$::=$	types
	B	basic type
	$\mid T$	tag type
	$\mid V$	all values
	$\mid \{\tau\}$	set of τ
	$\mid (\tau, \ldots, \tau)$	tuple type
	$\mid [\tau]$	sequence of τ
	$\mid \tau \to \tau$	function type
	$\mid \tau \oplus \tau$	disjoint union

$$e\ S \overset{[]}{\longmapsto} e\ S$$

$$\frac{\begin{array}{c} e_1\ S_1 \overset{m_1}{\longmapsto} e_2\ S_2 \\ e_2\ S_2 \overset{m_2}{\longmapsto} e_3\ S_3 \end{array}}{e_1\ S_1 \overset{m_1 \#\! \# m_2}{\longmapsto} e_3\ S_3}$$

$$\frac{\begin{array}{c} e_1\ S_1 \overset{m}{\longmapsto} e_2\ S_2 \\ e_3(\phi_1(S_2)) \overset{\phi_2(m)}{\longmapsto} e_4(\phi_1(S_2))\ \forall S_1, m \end{array}}{(\phi_1, \phi_2)e_1 = e_3}$$

Figure 2: Object Calculations

$$\frac{\begin{array}{c} e_1 \ S_1 \overset{m}{\longmapsto} e_1' \ S_1' \\ e_2 \ S_2 \overset{m}{\longmapsto} e_2' \ S_2' \end{array}}{(\text{coprod } e_1 \ e_2)(S_1 \oplus S_2) \overset{m}{\longmapsto} (\text{coprod } e_1' \ e_2', S_1' \oplus S_2')}$$

$$\frac{\begin{array}{c} e_1 \ S_1 \overset{m_1}{\longmapsto} e_1' \ S_1' \\ e_2 \ S_2 \overset{m_2}{\longmapsto} e_2' \ S_2' \\ \vdash S_1 \times S_2, \vdash S_1' \times S_2' \end{array}}{(\text{prod } e_1 \ e_2)(S_1 \times S_2) \overset{\text{zip } m_1 \ m_2}{\longmapsto} (\text{prod } e_1' \ e_2', S_1' \times S_2')}$$

$$\frac{\begin{array}{c} \phi(e_2) = e_1 \\ (\phi_1 \circ \phi)e_2 = (\phi_2 \circ \phi)e_2 \end{array}}{\text{eq } e_1 \ \phi_1 \ \phi_2 = (e_2, \phi)}$$

Figure 3: System Construction Operators

A *pre-system behaviour*, of type P is a function that expects to be supplied with a set of states. The result is a *system behaviour* of type O that expects a set of input messages and produces a replacement system behaviour and a set of output messages. A *system state* of type Σ is either a single object state or a pair of system states. A *system message* of type M is either a set of object messages or a pair of system messages. System behaviour types are defined below:

$$P = \{\Sigma\} \rightarrow (O, M)$$
$$O = M \rightarrow (O, M)$$
$$\Sigma = (T, V) \oplus (\Sigma, \Sigma)$$
$$M = \{(T, T, V)\} \oplus (M, M)$$

Object calculations are represented by the transition relation $\longmapsto$ which is defined in figure 2. Each transition is labelled with sequences of trees of input output messages. The operator env associates all atomic state values with a name relative to a given behaviour function, the result is a partial function ρ from names to values. An object calculation $e \ S \overset{m}{\longmapsto} e' \ S'$ is *well formed* when all output messages produced by each transition are input messages in the next transition.

Object calculation morphisms are pairs of functions (ϕ_1, ϕ_2) such that ϕ_1 is a mapping between object states and ϕ_2 is a mapping between sequences of input output messages. Such a morphism can be applied to a behaviour function e in λ_o to produce a new function $(\phi_1, \phi_2)e$ whose behaviour is given in terms of a mapping on e-calculations as shown in figure 2. Composition of object calculation morphisms is defined component-wise as follows: $(\phi_1, \phi_2) \circ (\phi_3, \phi_4) = (\phi_1 \circ \phi_3, \phi_2 \circ \phi_4)$. The type of a calculation morphism is $\Phi = (\{\Sigma\} \rightarrow \{\Sigma\}, [M] \rightarrow [M])$.

3.2 Constructing Systems

The state of a system of objects is a set of binary trees. The leaves of each tree are labelled with object states. Views of the same object may occur at different leaves in the tree providing that they are consistent. A system state S is *consistent* $\vdash S$ when it is a set of possible states for the same object t: $\vdash \bigcup_{i=1,n}\{(t, \rho_i)\}$, when it is the composition of two different object states: $\vdash \bigcup_{i=1,n}\{(t_1, \rho_i)\} \times \bigcup_{j=1,m}\{(t_2, \rho_j)\}$ such that $t_1 \neq t_2$, when it is the composition of two views of the same object such that attribute names occurring in both have the same values: $\vdash \bigcup_{i=1,n}\{(t, \rho_i)\} \times \bigcup_{j=1,m}\{(t, \rho_j)\}$ when $\rho_i(n) = \rho_j(n)$ for all $i, j, n \in \text{dom}(\rho_i) \cap \text{dom}(\rho_j)$, and finally when pair-wise decomposition of the state is well defined: $\vdash S_1 \times S_2 \times S_3$ when $\vdash S_1 \times S_2, \vdash S_1 \times S_3$ and $\vdash S_2 \times S_3$.

Systems are constructed from objects using the operators $\times : O \rightarrow O \rightarrow (O, \Phi, \Phi)$, $+ : O \rightarrow O \rightarrow (O, \Phi, \Phi)$ and $\text{eq} : O \rightarrow \Phi \rightarrow \Phi \rightarrow (O, \Phi)$. The semantics of these operators is given in terms of system calculations. Operator $\times$ is used to construct a system from its components, operator $+$ is used to construct alternative possible behaviours and eq

is used to express system constraints. System construction is defined using the operators in figure 3 where $\oplus$ is disjoint set union and zip merges pairs of sequences to produce sequences of pairs. The operators $\mathrm{prod} : O \to O \to O$ and $\mathrm{coprod} : O \to O \to O$ are used to construct products and coproducts consisting of behaviour functions and associated behaviour morphisms. They are defined by extending the λ_o-convertibility relation as follows:

$$\frac{\begin{array}{c} \pi_1(\mathrm{prod}\ e_1\ e_2) = e_1 \\ \pi_2(\mathrm{prod}\ e_1\ e_2) = e_2 \end{array}}{e_1 \times e_2 = (\mathrm{prod}\ e_1\ e_2, \pi_1, \pi_2)}$$

$$\frac{\begin{array}{c} \iota_1\ e_1 = \mathrm{coprod}\ e_1\ e_2 \\ \iota_2\ e_2 = \mathrm{coprod}\ e_1\ e_2 \end{array}}{e_1 + e_2 = (\mathrm{coprod}\ e_1\ e_2, \iota_1, \iota_2)}$$

The theory λ_o is extended with equivalences for the underlying operators prod, coprod and eq. In each case a one step transition defines term equivalence, for example:

$$\frac{(\mathrm{prod}\ e_1\ e_2)\ S \overset{[(I,O)]}{\longmapsto} e_3\ S'}{\mathrm{prod}\ e_1\ e_2\ S\ I = (e_3\ S', O)}$$

Products and coproducts must observe some simple algebraic properties given in the following theorems.

Theorem 1 *Let $e_t(t)$ be a terminal object behaviour defined: $e_t(t)(*)(I) = (e_t(t)(*), \emptyset)$. Then, $e \times e_t(t) = e = e_t(t) \times e$.*

The following proof shows that there exists an isomorphism between e and $e \times e_t(t)$ (and equivalently e and $e_t(t) \times e$). Define an object morphism (ϕ_1, ϕ_2) as:

$$(\phi_1, \phi_2) : e \times e_t(t) \to e$$
$$\phi_1(\cup\{(\sigma_i, (t, *))\}) = \cup\{\sigma_i\}$$
$$\phi_2(m) = \begin{cases} [] & \text{when} \quad m = [] \\ [(I, O)] & \text{when} \quad m = [((I, O), (\{*\}, \emptyset)] \\ \phi_2(m_1) + \phi_2(m_2) & \text{when} \quad m = m_1 + m_2 \end{cases}$$

The inverse $(\phi_1^{-1}, \phi_2^{-1}) : e \to e \times e_t(t)$ is well defined and therefore: $(\phi_1^{-1}, \phi_2^{-2}) \circ (\phi_1, \phi_2) = \mathrm{Id}_e$ and $(\phi_1, \phi_2) \circ (\phi_1^{-1}, \phi_2^{-1}) = \mathrm{Id}_{e \times e_t(t)}$. A similar argument is used to show that $e \times e_t(t)$ is isomorphic to $e_t(t) \times e$. QED.

Theorem 2 *System composition is associative, i.e. $(e_1 \times e_2) \times e_3 = e_1 \times (e_2 \times e_3)$*

The following proof sketch shows that the required isomorphism exists. Firstly define an object morphism $(\phi_1, \phi_2) : (e_1 \times e_2) \times e_3 \to e_1 \times (e_2 \times e_3)$:

$$\phi_1(\cup\{((v_1, v_2), v_3)\}) = \cup\{(v_1, (v_2, v_3))\}$$
$$\phi_2(m) = \begin{cases} [] & \text{when} \quad m = [] \\ [(p_1, (p_2, p_3))] & \text{when} \quad m = [((p_1, p_2), p_3)] \\ \phi_2(m_1) + \phi_2(m_2) & \text{when} \quad m = m_1 + m_2 \end{cases}$$

It is straightforward to define $(\phi_1^{-1}, \phi_2^{-1})$. QED.

Theorem 3 *The system construction operator $\times$ distributes over $+$, i.e. $e_1 \times (e_2 + e_3) = (e_1 \times e_2) + (e_1 \times e_3)$.*

The following proof uses the transition semantics of both sides of the equation to show that they are equivalent. From $e_1\ S_1 \overset{m_1}{\longmapsto} e_1'\ S_1'$, $e_2\ S_2 \overset{m_2}{\longmapsto} e_2'\ S_2'$ and $e_3\ S_3 \overset{m_2}{\longmapsto} e_3'\ S_3'$ we get the following:

$$(e_1 \times (e_2 + e_3))(S_1 \times (S_2 \oplus S_3)) \overset{\mathrm{zip}\ m_1, m_2}{\longmapsto}$$
$$(e_1' \times (e_2' + e_3'))(S_1' \times (S_2' \oplus S_3'))$$
$$((e_1 \times e_2) + (e_1 \times e_3))((S_1 \times S_2) \oplus (S_1 \times S_3)) \overset{\mathrm{zip}\ m_1, m_2}{\longmapsto}$$
$$((e_1' \times e_2') + (e_1' \times e_3'))((S_1' \times S_2') \oplus (S_1' \times S_3'))$$

Since $P \times (Q \oplus R) = ((P \times Q) \oplus (P \times R))$ for any sets P, Q and R then we conclude that the two calculations given above are equivalent. QED.

3.3   System Refinement

System development through step-wise refinement is attractive since it allows abstract models to be developed early in the life-cycle and then refined to concrete implementations through a series of verified transformations. Consider two behaviour functions e_1 and e_2 such that e_2 is a more concrete version of e_1. Typically, the states of e_2 will be related to those of e_1 but will involve more components and inter-relationships. For example, object-oriented design promotes the use of encapsulation whereby structured data is implemented as a collection of objects whose detail is hidden behind method interfaces. The calculations of e_1 will be more abstract than those of e_2; e_1 may perform complex tasks in a single computation step whereas e_2 must observe implementation constraints imposed by the target system.

If e_1 is an abstract version of the required system behaviour and e_2 is a (relatively) concrete version then e_2 must do everything that e_1 can do subject to an appropriate transformation on states and calculations. Furthermore, if e_1 is complete then e_2 must not introduce any behaviour that is inconsistent with that defined by e_1.

A *behaviour refinement* from e_1 to e_2 is a pair of mappings $(\gamma_1, \gamma_2) : e_1 \to e_2$ such that for every abstract calculation: $e_1 \ S_1 \overset{m}{\longmapsto} e_1' \ S_1'$ there exists a concrete calculation: $e_2 \ S_2 \overset{\gamma_2(m)}{\longmapsto} e_2' \ S_2$ such that $\gamma_1(S_2) = S_1$ and $\gamma_1(S_2') = S_1'$.

Theorem 4 *If* $(\gamma_1, \gamma_2) : e_1 \to e_2$ *and* $(\gamma_1', \gamma_2') : e_2 \to e_3$ *are two refinements, then* $(\gamma_1 \circ \gamma_1', \gamma_2' \circ \gamma_2) : e_1 \to e_3$ *is also a refinement.*

Theorem 5 *If* $(\gamma_1, \gamma_2) : e_1 \to e_2$ *is a refinement then* $(\gamma_1, \gamma_2) \times \mathrm{Id}_e : e_1 \times e \to e_2 \times e$ *is also a refinement.*

3.4   Message Passing

Computation occurs in an object-oriented system in terms of message passing. A behaviour is expressed in the design notation as a function which maps incoming messages to a pair $(e \ S, O)$ where $e \ S$ is a replacement behaviour and O is a set of outgoing messages. Once the messages O have been produced, the behaviour is immediately ready to handle new incoming messages as specified by e.

The basic model of message handling is therefore *asynchronous*. This decision arises because object-oriented design notations can express both synchronous and asynchronous message passing. Typically there are different notations to express *send message and wait for reply* and *send message without waiting for reply*.

Basing the semantic model on asynchronous message passing does not preclude synchronous message passing since an asynchronous model which incorporates replacement behaviours can implement synchronous messages [Agh86] [Agh91]. A message $m \in O$ is sent synchronously when e is a behaviour that waits for an incoming message m' such that m' is the response to m. When m' is received the behaviour reverts to its original functionality.

Variations on the synchronous model described above are possible. For example, the waiting behaviour may permit a sub-set of the functionality, or may implement a priority based interrupt mechanism, or may allow the behaviour to send messages to itself.

The example program development described in this paper uses a form of synchronous message passing. It is convenient to add syntactic sugar to the design notation capturing this form of message passing. The sugar is a form of **let** expression occurring in the context of a behaviour function as follows:

$$agent\{(t, v)\}\{m\} =$$
$$\quad \textbf{case } m \textbf{ of}$$
$$\qquad \dots$$
$$\qquad p_1 \to$$
$$\qquad\quad \textbf{let } p_2 \leftarrow e_1$$
$$\qquad\quad \textbf{in } e_2$$
$$\qquad \dots$$
$$\quad \textbf{end}$$

A **let** expression occurs in the context of a behaviour, represented here by the function *agent*. The expression e_1 is a set of messages or a single message which is to be sent in response to receiving a message matching p_1. The
Figure 4: A Widget Dispensing Machine

behaviour *agent* may carry on handling messages[1]. Any incoming message matching p_2 is a response to the messages e_1; the response of *agent* is defined by e_2.

The semantics of **let** is defined by a syntax translation to the basic design notation:

$$agent\{(t,v)\}\{m\} =$$
$$\quad \textbf{case } m \textbf{ of}$$
$$\quad\quad \ldots$$
$$\quad\quad\quad p_1 \rightarrow (agent\{(t,v)\} + wait, e_1)$$
$$\quad\quad\quad\quad \textbf{whererec } wait\{m\} =$$
$$\quad\quad\quad\quad\quad \textbf{case } m \textbf{ of}$$
$$\quad\quad\quad\quad\quad\quad p_2 \rightarrow e_2$$
$$\quad\quad\quad\quad\quad\quad \textbf{else } (wait, \emptyset)$$
$$\quad\quad\quad\quad\quad \textbf{end}$$
$$\quad\quad \ldots$$
$$\quad \textbf{end}$$

The locally created behaviour *wait* is used to extend *agent* with a handler for the response to messages e_1. Typically, when the response occurs, e_2 will revert back to the original behaviour *agent*.

4   Requirements and Initial Specification

Software to control a simple machine (see figure 4) for dispensing widgets is required. The machine consists of a store of widgets, 4 buttons, an output tray and a two-tone beeper. The buttons are labelled $0 - 3$. In order to dispense a widget the operator must press the buttons 1, 2 and 3 in order. At any time the operator may cancel the operation by pressing 0. Widgets are removed from the store and delivered to the output tray when they are dispensed. If the operation succeeds the beeper makes a high beep otherwise the beeper makes a low beep. Each widget has a unique identity.

An initial attempt at the required behaviour is shown in figure 5. The behaviour function M has two state components s and o that are sets of widgets representing the store and output respectively. Input messages $0 - 2$ cause no state change and no output messages. Input message 3 from source object t' causes a widget to be dispensed and added to the output tray o if available in the store s. A boolean reply is sent to the source of the message causing a high beep (*true*) if successful and a low beep (*false*) if the operation failed. The initial behaviour is under specified since it includes the required behaviour, but also permits illegal sequences of buttons.

---

[1] In fact we only require *agent* to handle messages which it sends to itself. The extra machinery for this feature is straightforward but would clutter the example so we omit it.

$$M\{(t, (s, o))\}\{m\} =$$

$$\textbf{case } m \textbf{ of}$$
$$0 \rightarrow (M\{(t, (s, o))\}, \emptyset)$$
$$1 \rightarrow (M\{(t, (s, o))\}, \emptyset)$$
$$2 \rightarrow (M\{(t, (s, o))\}, \emptyset)$$
$$(t', 3) \rightarrow$$
$$\textbf{case } s \textbf{ of}$$
$$\emptyset \rightarrow (M\{(t, (s, o))\}, \{(t, t', \textit{false})\})$$
$$\{w\} \cup s' \rightarrow (M\{(t, (s', o \cup \{w\}))\}, \{(t, t', \textit{true})\})$$
$$\textbf{end}$$
$$\textbf{end}$$

Figure 5: Initial Specification

5 A Simple System Invariant

A simple system property is that the number of widgets available in both the store and the output tray is an invariant, *i.e.* pushing buttons cannot cause widgets to be introduced or lost. This can be expressed as a behaviour:

$$I\{(t, w)\}\{m\} = (I\{(t, w)\}, \emptyset)$$

together with a behaviour morphism from M to I that translates an M state (s, o) to an I state $\#s + \#o$ and is identity everywhere else. In order to show that I is an invariant we show that the limit on the diagram M is the same as the limit on the diagram $M \rightarrow I$.

Theorem 6 *I is an invariant of M.*

The proof shows that there exists a total behaviour morphism $\phi : M \rightarrow I$ such that a limit on the diagram containing M is unchanged (isomorphic to) a limit on the diagram containing $\phi : M \rightarrow I$. The mapping is defined as follows:

$$\phi_1\{(t, (s, o))\} = \{(t, \#s + \#o)\}$$
$$\phi_2(m) = \begin{cases} [] & \text{when } m = [] \\ [(i, \emptyset)] & \text{when } m = [(i, \_)] \\ \phi_2(m_1) + \phi_2(m_2) & \text{when } m = m_1 + m_2 \end{cases}$$

Proposition 1 *The behaviour morphism ϕ defines a total graph homomorphism.*

The following proof is by induction on the length of object calculations. Consider any M transition $M\{(t, (s, o))\} \xrightarrow{m} M\{(t, (s', o'))\}$ and proceed by case analysis on the message sequence m. Note that we omit any message information that is not relevant or can be inferred from context.

When $m = [(0, \emptyset)]$, $\phi_2(m) = m$, $\{(t, (s, o))\} = \{(t, (s', o'))\}$ and therefore $\phi_1\{(t, (s, o))\} = \phi_1\{(t, (s', o'))\}$. The same argument holds for $m = []$, $m = [(1, \emptyset)]$ and $m = [(2, \emptyset)]$. When $m = [(3, O)]$, $\phi_2(m) = [(3, \emptyset)]$ and either $s = \emptyset$ or $s \neq \emptyset$; we proceed by case analysis on s. When $s = \emptyset$, $O = \{(t, t', \textit{false})\}$, $\{(t, (s, o))\} = \{(t, (s', o'))\}$ and therefore $\phi_2\{(t, (s, o))\} = \phi_2\{(t, (s', o'))\}$. When $s = \{w\} \cup s'$, $o' = \{w\} \cup o$ and $O = \{(t, t', \textit{true})\}$, therefore:

$$\phi_2\{(t, (s, o))\} = \{(t, \#(\{w\} \cup s') + \#(o' - \{w\}))\}$$
$$= \{(t, 1 + \#s' + \#o' - 1)\}$$
$$= \phi_2\{(t, (s', o'))\} + 1 - 1$$
$$= \phi_2\{(t, (s', o'))\}$$

When $m = m_1 + m_2$ then assume by induction that the invariant is true for both $M\{(t, (s, o))\} \xrightarrow{m_1} M\{(t, (s', o'))\}$ and $M\{(t, (s', o'))\} \xrightarrow{m_2} M\{(t, (s'', o''))\}$ and is therefore true by definition for $M\{(t, (s, o))\} \xrightarrow{m_1 + m_2} M\{(t, (s'', o''))\}$. It remains to show that M is a limit on diagrams containing M and $\gamma : M \rightarrow I$ respectively.

Proposition 2 *M is a limit on the diagram containing M and $\text{Id}_M : M \rightarrow M$.*
$$P\{(t,\sigma)\}\{m\} =$$
$$\textbf{case } m \textbf{ of}$$
$$0 \to (P\{(t,A)\},\emptyset)$$
$$1 \to \textbf{case } \sigma \textbf{ of } A \to (P\{(t,B)\},\emptyset) \textbf{ end}$$
$$2 \to \textbf{case } \sigma \textbf{ of } B \to (P\{(t,C)\},\emptyset) \textbf{ end}$$
$$3 \to \textbf{case } \sigma \textbf{ of } C \to (P\{(t,A)\},\emptyset) \textbf{ end}$$
$$\textbf{end}$$

Figure 6: Legal Message Sequences

The proof follows directly from the properties of the identity morphism. Now consider the second diagram. Firstly construct a product $M \times I$ in which nodes are labelled with states from the free product $states(M) \times states(I)$. Note that the product contains states that are legal $\{((t_1,(s,o)),(t_2,\#s+\#o))\}$ and those that are not.

Now construct an equalizer $e : L \to M \times I$ such that $\gamma \circ \pi_1 \circ e = \pi_2 \circ e$:

$$
\begin{array}{c}
L \\
\downarrow e \\
M \times I \\
\swarrow_{\pi_2} \quad \searrow_{\pi_1} \\
M \xrightarrow{\gamma} I
\end{array}
$$

The behaviour L is a limit on the diagram and contains just those states that are legal. The limit L is not exactly the same as M but there exists an isomorphism between them. Therefore we conclude that $\gamma : M \to I$ is a property of M. QED

6   Removing Illegal Message Sequences

The behaviour M is *under specified* since it permits buttons on the machine to be pressed in illegal sequences. Object-oriented design notations such as UML restrict behaviours such as M using state transition models that impose orderings on sequences of permitted message calls. The machine consists of three states referenced as 1, 2 and 3.

The initial state for the machine is 1. Button 1 may only be pressed in state 1 causing a state change to 2. Button 2 may only be pressed in state 2 causing a state change to 3. Button 3 may only be pressed in state 3 causing a state change to 1; a widget is dispensed as a side effect. Button 0 may be pressed in any state causing a change to state 1.

The state transition machine is expressed as a behaviour function P in figure 6. The behaviour describes a single state component σ whose value is the machine state. The behaviour handles all machine messages making appropriate state changes but otherwise does nothing.

Behaviour M includes all correct behaviour but also includes incorrect behaviour. Applying the constraint P to M will produce just the required behaviour. The constraint is applied by combining M and P using the behaviour combination operator $\times$. This produces a new behaviour $M' = M \times P$ shown in figure 7. The behaviour M' has a state (s,o,σ) that is the combination of states from M and P. Message dispatch has been combined so that the conditions from both M and P are taken into account. The multiple patterns $(0,\sigma)$ for all states σ has been combined into a single pattern $(0, \_)$ since the same transition occurs in all cases. Notice that the machine simply ignores buttons that are pressed out of sequence and that if an operator gets into trouble they may always press 0 to reset the machine.

7   Object-Oriented Encapsulation

The behaviour M' does not observe the principle of encapsulation since the state (s,o) accesses state components of both s and o. In order to be object-oriented, the behaviour M' must reference both s and o as objects. Accessing and

$$
\begin{aligned}
M'&\{(t,(s,o,\sigma))\}\{m\} = \\
&\textbf{case } (m,\sigma) \textbf{ of} \\
&\quad (0,\_) \to (M'\{(t,(s,o,A))\},\emptyset) \\
&\quad (1,A) \to (M'\{(t,(s,o,B))\},\emptyset) \\
&\quad (2,B) \to (M'\{(t,(s,o,C))\},\emptyset) \\
&\quad (t',(3,C)) \to \\
&\qquad \textbf{case } s \textbf{ of} \\
&\qquad\quad \emptyset \to (M'\{(t,(s,o,A))\},\{(t,t',\textit{false})\}) \\
&\qquad\quad \{w\}\cup s' \to (M'\{(t,(s',o\cup\{w\},A))\},\{(t,t',\textit{true})\}) \\
&\qquad \textbf{end} \\
&\textbf{end}
\end{aligned}
$$

Figure 7: Combining M and P

$$
\begin{aligned}
S&\{(t,Q)\}\{m\} = \\

&\quad \textit{store}(w) \to (O\{(t,Q\cup\{w\})\},\emptyset) \\
&\textbf{end}
\end{aligned}
$$

Figure 8: Store and Output Behaviour

changing state in both s and o must occur via message passing.

Although both s and o are represented as sets of widgets, they are used in different ways. These differences may result in radically different implementation strategies and so we implement each as a separate behaviour in figure 8. A store behaviour S handles messages *empty* and *get*. The former replies with *true* when the store is empty and the latter replies with an element of the store selected at random. An output tray behaviour O handles a single message *store* containing a widget x. The widget is added to the output tray.

The behaviour function M' must be refined in order to use references to the store and output tray. The result is a new behaviour function M'' shown in figure 9. When M'' receives a message 3 from object t' in state 3 it sends a message *empty* to the store and waits for the reply. If the store is not empty then M'' sends it another message *get* and waits for a widget to be returned. On receiving the widget x, M'' sends a *store*(x) message to the output tray. Finally, M'' replies to t' with *true* or *false*.

Theorem 7 $S \times M'' \times O$ *is a refinement of* M'

$$M''\{(t, (s, o, \sigma))\}\{m\} =$$

$\quad$ **case** (m, σ) **of**

$\qquad (0, \_) \to (M''\{(t, (s, o, A))\}, \emptyset)$

$\qquad (1, A) \to (M''\{(t, (s, o, B))\}, \emptyset)$

$\qquad (2, B) \to (M''\{(t, (s, o, C))\}, \emptyset)$

$\qquad (t', (3, C)) \to$

$\qquad\quad$ **let** $b \leftarrow \{(t, s, empty)\}$

$\qquad\quad$ **in** **if** $not(b)$

$\qquad\qquad$ **then** **let** $w \leftarrow \{(t, s, get)\}$

$\qquad\qquad\qquad$ **in** $(M''\{(t, (s, o, A))\}, \{(t, t', true), (t, o, store(w))\})$

$\qquad\qquad$ **else** $(M''\{(t, (s, o, A))\}, \{(t, t', false)\})$

$\quad$ **end**

Figure 9: Encapsulating the Store and Output Tray

A proof of correctness for a refinement is established by defining a refinement homomorphism (γ_1, γ_2):

$$\gamma_1\{(t, (t_s, t_o, \sigma)), (t_s, s), (t_o, o)\} = \{(t, (s, o, \sigma))\}$$

$$\gamma_2(m) = \begin{cases} [] & \text{when} \quad m = [] \\ [(i, \emptyset)] & \text{when} \quad m = [(i, \emptyset)] \forall i \in 0 \dots 2 \\ 3, get, empty, true, false & \text{when} \quad m = [(3, \{false\})] \\ 3, get, empty, false, get, w, true, store(w) & \text{when} \quad m = [(3, \{true\})] \\ \gamma_2(m_1) + \gamma_2(m_2) & \text{when} \quad m = m_1 + m_2 \end{cases}$$

Theorem 8 $(\gamma_1, \gamma_2) : M' \to S \times M'' \times O$ *is a refinement homomorphism.*

The proof must establish that for all transitions $M'(\gamma_1(W)) \overset{m}{\longmapsto} M'(\gamma_1(W'))$ there exists a transition $(S \times M'' \times O)W \overset{\gamma_2(m)}{\longmapsto} (S \times M'' \times O)W'$. The refinement is *complete* if it holds for all transitions performed by M' and is *sound* if it holds for all transitions performed by $S \times M'' \times O$. The proof is by induction on the structure of m; we proceed by case analysis of m.

$\quad$ When $m = []$, since $\gamma_2(m) = []$, $W = W'$ and $\gamma_1(W) = \gamma_1(W')$. When $m = [(\{0\}, \emptyset)]$ then $\gamma_2(m) = [(\{0\}, \emptyset)]$ and for any $W = \{(t, (t_s, t_o, x), (t_s, s), t_o, o)\}$, $W' = \{(t, (t_s, t_o, A)), (t_s, s), (t_o, o)\}$, therefore $M'(\gamma_1(W)) \overset{m}{\longmapsto} M'(\gamma_1(W'))$. When $m = [(\{1\}, \emptyset)]$ and $m = [(\{2\}, \emptyset)]$ the proof has the same structure as that for $m = [(\{0\}, \emptyset)]$. When $m = [(\{3\}, \{b\})]$ with $b = false$ then $\gamma_2(m) = get, empty, true, false$, $W = \{(t, (t_s, t_o, C)), (t_s, \emptyset), (t_o, o)\}$, therefore $W' = W$ and $M'(\gamma_1(W)) \overset{m}{\longmapsto} M'(\gamma_1(W'))$. When $m = [(\{3\}, \{b\})]$ with $b = true$ then $\gamma_2(m) = get, empty, false, get, w, true, store(w)$, $W = \{(t, (t_s, t_o, C)), (t_s, \{w\} \cup s), (t_o, o)\}$ and therefore:

$$W' = \{(t, (t_s, t_o, A)), (t_s, s), (t_o, \{w\} \cup o)\}$$
$$M'(\gamma_1(W)) \overset{m}{\longmapsto} M'(\gamma_1(W'))$$

$\quad$ When $m = m_1 + m_2$ we assume by induction than the theorem holds for the sequences m_1 and m_2 and therefore it holds for m by the transitivity of $\longmapsto$. QED

8 Concrete Data Representation

The behaviours S and O do not uphold the principle of concrete data representation. Java does not provide a representation for data structures that is fully consistent with sets. One possible refinement for S and O is to use the standard behaviour for indexed sets that can be implemented directly in Java using either arrays or vectors. The store and output tray behaviours are refined as shown in figure 10.

$$S'\{(t,(Q,i))\}\{m\} =$$
$$\quad \textbf{case } m \textbf{ of}$$
$$\qquad (t', empty) \rightarrow (S'\{(t,(Q,i))\}, \{(t,t',i=-1)\})$$
$$\qquad (t', get) \rightarrow (S'\{(t,(Q,i-1))\}, \{(t,t',Q[i])\})$$
$$\quad \textbf{end}$$

$$O'\{(t,(Q,i))\}\{m\} =$$
$$\quad \textbf{case } m \textbf{ of}$$
$$\qquad store(x) \rightarrow (O'\{(t(Q[i]:=x,i+1))\}, \emptyset)$$
$$\quad \textbf{end}$$

Figure 10: Refinement of Store and Output Tray Behaviours

The states of S' and O' consist of an indexed set Q and an index i. The values in Q are indexed by integers from 0 upwards and $i+1$ is the size of the indexed set. Given an indexed set Q, the value associated with index k is $Q[k]$. The indexed set is extended with a value x indexed by k to produce $Q[k]:=x$.

Theorem 9 $S' \times M'' \times O'$ *is a legal refinement of* $S \times M'' \times O$

A proof follows from theorem 5 and the existence of two refinements from S to S' and from O to O'. The refinement $(\gamma_1, \gamma_2) : S \rightarrow S'$ is defined as follows:

$$\gamma_1\{(t,(Q,i))\} = \{(t, \{Q[j] \mid j \in 0 \ldots i\})\}$$
$$\gamma_2(m) = m$$

Notice that (γ_1, γ_2) reduces the non-determinism occurring in S since the *get* method always returns widgets in a particular order for a given state.

9 Implementation in Java

Composition of refinement morphisms by theorem 4 shows the resulting system $S' \times M'' \times O'$ to be a valid refinement of the initial specification M. The system is implemented by identifying a one-to-one correspondence between the design components and programming language components that give rise to the same behaviour. Each behaviour function corresponds to a Java class. Each state component of a behaviour function corresponds to a private field. Each message handled by a class corresponds to a public method.

The implementation is given in figure 11. During implementation we may identify certain behaviours that are consistent with behaviours provided by existing Java classes. This occurs here with S' and O' both of which are consistent with the behaviour of `Vector`.
