Running title: Ezh2 correlates with aggressiveness

## Abstract

1  
2 Polycomb group (PcG) proteins are important to the regulation of hematopoiesis by regulating  
3  
4 chromatin compaction and silencing genes related to differentiation and cell cycle. The  
5  
6 overexpression of Ezh2 and Bmi-1/PCGF4, has been implicated in solid organ cancers. Meanwhile,  
7  
8 Mel-18/PCGF2 was reported as a tumor suppressor. The detailed expression profiles of PcG  
9  
10 proteins and diagnostic significance in malignant lymphomas are still unknown. In this study, we  
11  
12 analyzed the expression levels of Ezh2, Bmi-1, Mel-18 and Ki67 in 197 Hodgkin's and non-  
13  
14 Hodgkin's lymphoma patient samples and in lymphoma cell lines using immunohistochemical,  
15  
16 fluorescent immunocytochemical and Western blotting. Immunohistochemical staining showed  
17  
18 that Ezh2 expression was significantly increased in aggressive compared to indolent subtypes of B-  
19  
20 cell neoplasms ( $P=0.000\sim 0.030$ ) while no significant differences were found in Bmi-1 expression  
21  
22 among these subtypes. Compared to the normal counterpart, T-cell lymphomas showed significant  
23  
24 overexpression of Bmi-1 ( $P=0.011$ ) and Ezh2 ( $P=0.000$ ). The Ki67 labeling index showed a  
25  
26 positive correlation with Ezh2 in B-cell lymphomas (*correlation coefficient: Co*=0.983,  $P=0.000$ )  
27  
28 and T/NK- cell lymphomas (*Co*=0.629,  $P=0.000$ ). Fluorescent immunohistochemical staining  
29  
30 showed co-expression of Ezh2 and Ki67 in the same tumor cells, indicating that Ezh2 expression  
31  
32 correlates with cell proliferation. Both B-and T/NK cell neoplasms showed low expression of Mel-  
33  
34 18 and high expression of both Bmi-1 and Ezh2. In conclusion, lymphomas show high expression  
35  
36 of Ezh2 in the aggressive variants, and a dominance of polycomb repressive complex PRC1.4 over  
37  
38 PRC1.2. Coexpression of Bmi-1 and Ezh2 is a characteristic of aggressive lymphomas. Ezh2  
39  
40 correlates with the proliferation and aggressive nature of non-Hodgkin's lymphomas.

## **Introduction**

1  
2 Non-Hodgkin's lymphomas show a wide spectrum of morphology and variability in  
3  
4 prognosis between different subtypes. Genetic abnormalities are not enough to explain the entire  
5  
6 multi-step lymphomagenesis process. Aberrant epigenetic changes, including DNA methylation,  
7  
8 histone modifications, chromatin remodeling and non-coding RNAs (ncRNAs) also contribute to the  
9  
10 development and progression of malignancy [1-3].

11  
12  
13 Polycomb group (PcG) proteins are important regulators of lymphopoiesis that suppress gene  
14  
15 expression through epigenetic modifications [4]. They form large multimeric complexes known as  
16  
17 Polycomb repressive complexes (PRCs), which bind to chromatin and control histone modifications.  
18  
19 In mammals, there are two main PcG complexes: Polycomb repressive complexes (PRC1) and 2  
20  
21 (PRC2). PRC2 includes Enhancer of zeste homologue 2 (Ezh2), Eed, Suz12, RBBP4/7 and Jarid2 [5].  
22  
23 PRC1 complexes include several complexes that differ in their localization and function. So far, six  
24  
25 subgroups have been identified and numbered (PRC1.1~1.6). All of them contain RING1 A and  
26  
27 RING1 B enzymes, which ubiquitinate histone H2A at the lysine 119 residue [6]. Ezh2 is a histone3  
28  
29 lysine27 methyltransferase that generates H3K27me3, which is reported to be the binding site of  
30  
31 PRC1, resulting in the ubiquitination of histones [7, 8]. This association with H3K27me3 was recently  
32  
33 proven to be specific to PRC1.2 and PRC1.4 [6]. The interaction between PRC1 and PRC2 facilitates  
34  
35 chromatin compaction, silencing of important tumor suppressors and genes involved in development,  
36  
37 differentiation, adhesion, cell cycle progression and proliferation. Both groups are important  
38  
39 developmental regulators in both stem and cancer cells that help control the cell cycle,  
40  
41 immortalization and self-renewal of normal stem/progenitor cells [4, 9-11].

42  
43 Bmi-1/PCGF4 is a component of the PRC1.4 complex, and was described as a proto-  
44  
45 oncogene that induced lymphomas in mice. The upregulation of Bmi-1 was reported in a variety of  
46  
47 cancers, and sometimes correlated with a poor prognosis [6, 12-14]. Mel-18/PCGF2 is a component  
48  
49 of the PRC1.2 complex, and was previously described as a tumor suppressor that is expressed in the  
50  
51 normal state and suppressed in neoplastic conditions in gastric, prostate and breast cancers [15-17].  
52  
53 PRC1.2 and PRC1.4 complexes are formed, one with canonical PcG components (CBXs, PHCs and  
54  
55 SCMs) and one with RYBP or YAF2, in addition to Bmi-1/PCGF4 or Mel-18/PCGF2 [6].

1 Ezh2 overexpression has been reported in solid organ cancers, including breast, prostate and  
2 stomach cancer. It is associated with metastasis, poor prognosis and treatment failure [18-20]. Somatic  
3 gain of function mutations in the SET domain of Ezh2, which result in increased histone methylation  
4 levels, were reported in follicular lymphomas (FL) and diffuse large B cell lymphoma (DLBCL). This  
5 is in contrast to the loss-of-function mutations reported in patients with myeloid malignancies, most  
6 commonly in those with myelodysplastic/myeloproliferative neoplasms and myelofibrosis [21-23].  
7 However, a lot remains unknown about the expression profiles of PcG proteins and their significance  
8 in terms of the pathology of lymphoma, especially in T/NK-cell lymphomas. This study investigated  
9 the expression patterns of Bmi-1, Ezh2 and MeI-18 in different subtypes of B- and T/NK-cell  
10 neoplasms, and examined the possible correlation with Ki67 expression, as a marker of tumor  
11 proliferation.

## 27 **Materials and Methods**

### 28 **Patient samples**

29 Paraffin blocks of 197 lymphoma samples from the archives of the Department of Pathology,  
30 Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama University were used  
31 for the present analyses. The demographic data of the patients and the locations of the neoplasms are  
32 summarized in Supplemental Table S1. Reactive lymphoid hyperplasia (RLH, 8 specimens), tonsil (5  
33 specimens), inflammatory non-neoplastic skin lesions (4 specimens) and thymus (2 specimens) were  
34 used as normal controls. Informed consent was obtained from all patients for the analysis of their  
35 tissue samples. This study was approved by the Institutional Review Board of the Graduate School of  
36 Medicine, Dentistry and Pharmaceutical Sciences, Okayama University and related hospitals, in  
37 accordance with the Declaration of Helsinki. The classification of the neoplasms was done according  
38 to the REAL/WHO classification. DLBCL cases were further divided into two groups, germinal  
39 center type (DLBCL-GCB) and non-germinal center type (DLBCL non-GCB), according to the Hans  
40 algorithm [24, 25].

### 60 **Cell culture**

1 The cell lines and culture conditions are summarized in Supplemental Table S2. Peripheral  
2 blood mononuclear cells (PBMCs) and CD4<sup>+</sup> T-cells from healthy donors were used as normal  
3 controls. Immunomagnetic isolation was done using EasySep® Human CD4<sup>+</sup> T-Cell Enrichment Kit  
4 (#19052, Stemcell Technologies, Vancouver, BC, Canada). The Dynabeads® human T-cell activator  
5 CD3/CD28 was used to activate and expand human T-cells (Invitrogen, Oregon, USA).  
6  
7  
8  
9

### 10 **Immunohistochemical staining**

11 Paraffin blocks were retrieved, and new sections were used to ensure the quality of staining.  
12 Cases in which paraffin blocks were not available to make new sections were excluded. The following  
13 mouse monoclonal antibodies were used: Ezh2 (clone M18) [26, 27], Bmi-1 (Abcam, MA, USA),  
14 CD34 (Abcam, MA, USA), CD3 and CD20 (Novocastra, Newcastle upon Tyne, UK), CD56, MUM-1  
15 (Novocastra, Newcastle upon Tyne, UK), CD4, CD8 (Nichirei Biosciences Inc., Tokyo Japan), CD10,  
16 CD68, CD138, (Dako, Glostrup, Denmark), BCL6 (Santa Cruz Biotechnologies Inc., Texas, USA),  
17 rabbit anti-Mel-18 (Santa Cruz Biotechnologies Inc., Texas, USA) and anti-Ki67 (Novocastra,  
18 Newcastle upon Tyne, UK). Staining was done with a Leica BOND-MAX™ autostainer (Leica  
19 Biosystems, Melbourne, Vic., Australia). Both the intensity of staining and percentage of positive  
20 tumor cells were evaluated in 10 high-power fields by three investigators. A high Ki67 labeling index  
21 was defined as nuclear staining of  $\geq 20\%$  of tumor cells. Positivity was defined as  $\geq 25\%$  nuclear  
22 staining of tumor cells, in accordance with previous reports [14, 20]. Positive cases were further  
23 scored as (+), (++) and (+++) based on the intensity of the staining, which was judged by comparing it  
24 to internal control cells. Endothelial cells or adjacent normal/reactive lymphoid tissue served as an  
25 internal control for Bmi-1. For Ezh2, an adjacent germinal center in nodal and duodenal specimens, or  
26 the basal epithelial layer in the case of skin and mucous membrane specimens, was used as the  
27 internal control. For Mel-18, endothelial cells were used as the internal control. A control slide of  
28 either RLH or tonsil was also included in each staining run. For every case, the neoplastic nature of  
29 the stained cells was confirmed by its morphology and by using a selection from a panel of markers  
30 (including CD20, CD138, CD10, CD3, CD4, CD7, CD8, CD56, Cyclin-D1 and BCL2). A

1 combination of each marker (Ezh2, Bmi-1 or Ki67) with B- and T/NK cell markers (CD20, CD3,  
2 CD56, CD138) was done in normal lymphoid tissue and selected cases of lymphoma.  
3  
4  
5

### 6 **Double fluorescent immunocytochemical and immunohistochemical staining**

7  
8  
9 The cells were washed with PBS then processed via cytopspin ( $10^5$  per slide) and fixed in cold  
10 acetone. Blocking was done by incubation in 5% skim milk for five hours at room temperature. After  
11 washing, the cells were treated with a mixture of two primary antibodies for three to five hours at  
12 room temperature. Washing was repeated, then samples were incubated with a mixture of anti-mouse  
13 and anti-rabbit-IgG for two to three hours at room temperature. The primary antibodies included  
14 rabbit monoclonal anti-Ezh2 (Cell Signaling, Beverly, MA, USA) and mouse monoclonal anti-Bmi-1  
15 (Abcam, MA, USA). The secondary antibodies were anti-mouse IgG Alexa Flour 555 and anti-rabbit  
16 IgG Alexa Flour 488 (Invitrogen, Oregon, USA). Slides were mounted with SlowFade® Gold  
17 antifade reagent with DAPI (Invitrogen, Oregon, USA) and examined with a conventional  
18 immunofluorescence microscope (IX71, Olympus, Tokyo, Japan). The following combinations were  
19 used: Ezh2 with Bmi-1, Ezh2 with Ki67 and Bmi-1 with Ki67.

### 36 **Western blotting analysis**

37  
38 The Western blot analyses were performed as described previously [28]. Rabbit anti-Ezh2,  
39 mouse anti-Bmi-1, rabbit anti-Mel-18 (Santa Cruz Biotechnologies Inc., Texas, USA) and mouse anti-  
40 beta-actin (Sigma Aldrich, St Louis, USA) antibodies and HRP-labeled anti-rabbit or anti-mouse  
41 antibodies (NA9340V GE and NA9310V, respectively, GE Healthcare, little Chalfont  
42 Buckinghamshire, UK) were used for the analyses.

49  
50

### 51 **Statistical analysis**

52  
53 All statistical analyses were done with the SPSS version 11.5 software program. Person's Chi  
54 squared test and one-way ANOVA with the Bonferroni's correction were used to compare the  
55 different lymphoma subtypes. Spearman's and Pearson's coefficients were used for the correlation  
56 analyses of Bmi-1, Ezh2 and Ki67.

## **Results**

### **Expression of Bmi-1 and Ezh2 in normal lymphoid tissues**

In RLH, the expression of Bmi-1 and Ezh2 was mutually exclusive. Bmi-1 was mainly expressed in the mantle zone while Ezh2 was expressed in the germinal center; centroblasts showed stronger staining than centrocytes. CD138<sup>+</sup> plasma cells were Bmi-1<sup>+/-</sup> and Ezh2<sup>-</sup>. CD68<sup>+</sup> macrophages were Bmi-1<sup>-</sup>/Ezh2<sup>-</sup>. Interfollicular CD3<sup>+</sup> T, follicular CD4<sup>+</sup> T-helper cells and CD56<sup>+</sup> NK/T cells were mostly Bmi-1<sup>+</sup>/Ezh2<sup>-</sup> (Table 1 and Figure S1). The cutaneous CD3<sup>+</sup> T-cells were Ezh2 negative. In the normal thymus, the cortical thymocytes were mostly Ezh2<sup>+</sup>/Bmi-1<sup>-</sup>. In the medulla, the pattern was reversed; the dominant population of CD3<sup>+</sup> cells was Ezh2<sup>-</sup>/Bmi-1<sup>+</sup> (Table 1 and Figure S2). The staining intensity for Bmi-1 in both RLH and the thymus was generally weak to moderate (Table 1). **The normal stratified squamous epithelium covering the tonsils showed nuclear staining for Ezh2, mostly in the basal layers while Bmi-1 staining generally showed low expression (Figure S3).**

### **High expression of Bmi-1 and Ezh2 in Hodgkin's lymphoma and B-cell neoplasms**

In Hodgkin's lymphomas, the coexpression of both Bmi-1 and Ezh2 was found in the tumor cells in 9/10 cases (90%), but was not found in the reactive background cells (Table 1). In B-cell neoplasms, the overall expression of Bmi-1 was 84.4%. The staining intensity was generally moderate (72 cases) to strong (nine cases). Bmi-1 expression was found in all subtypes, ranging from 58.3% in Burkitt's lymphoma (BL) to 100% in four subtypes: Mantle cell lymphoma (MCL), chronic lymphocytic leukemia/small lymphocytic lymphoma (CLL/SLL), mucosa associated lymphoid tissue (MALT) lymphoma and plasmacytoma (PC) (Table 1). MCL showed a moderate staining in more than 90% of tumor cells in all cases. PC and plasma cell myeloma (PCM) showed a stronger staining intensity compared to the weak staining in 20% of normal CD138<sup>+</sup> plasma cells ( $X^2=8.718$ ,  $P=0.033$ ). In both PCM and PC, the percentage of positive tumor cells was above 80% in 10 cases (Table 1, Figures 1 and S1). MALT lymphoma expressed Bmi-1 in 100% of cases. Strong staining was noted in 7/10 cases (70%), and the percentage of positive tumor cells was more than 90% in all cases.

Follicular lymphoma grade 1 and 2 (FLG1-2) expressed Bmi-1 in 73.7% of cases, compared to the negative germinal center light zone (Table 1,  $X^2=14.246$ ,  $P=0.003$ ). DLBCL-GCB showed moderate to strong staining in 85.7% of cases (Table 1 and Figure 1). The expression in BL, DLBCL-GCB and FLG3 showed significant differences compared to the germinal center dark zone (Table 1,  $X^2=15.221$ ,  $P=0.002$ ), and the percentage of positive tumor cells was above 70% in 10 cases. No significant difference was found between FLG1-2 and follicular lymphoma grade 3 (FLG3) in either the percentage or intensity of staining. In addition, no difference was noted between the DLBCL-GCB and DLBCL non-GCB subtypes.

The overall expression of Ezh2 in B-cell neoplasms was 56.9% (Table 1). The expression varied among the different subtypes. The highest percentage of positivity was found in BL, FLG3 and DLBCL (100%, 87.5% and 85.7%, respectively). The percentage of positive tumor cells was generally greater than 80% in the three entities. FLG3 showed 87.5% positivity versus 57.8% in FLG1-2. The strongest staining intensity was seen in DLBCL-GCB, in which 8/14 cases (57.1%) showed stronger staining intensity than the germinal center dark zone while the staining in FLG3 was comparable to the latter (Table 1 and Figure 1). The difference in the expression of Ezh2 in BL, DLBCL-GCB and FLG3 compared to the germinal center dark zone was not significant ( $X^2=7.0279$ ,  $P=0.064$ ). FLG1-2 expressed Ezh2 in 57.8% of cases, and the expression was comparable to that of the light zone ( $X^2=5.836$ ,  $P=0.054$ ). In MCL, an enhanced expression of Ezh2 was noted in 66.7% of cases, compared to 3.5% of normal mantle zone cells. CLL/SLL expressed Ezh2 in 20% of cases. Plasma cell myeloma (PCM) expressed Ezh2 in 14.3% of cases while PC, lymphoplasmacytic lymphoma and MALT lymphoma were negative for Ezh2 (Table 1). Plasma cell neoplasms did not show any noticeable difference in Ezh2 expression levels compared to normal CD138+ cells ( $X^2=0.745$ ,  $P=0.388$ ) (Table1, Figures 1 and S1).

### **High expression of Bmi-1 and Ezh2 in T- and NK/T-cell non-Hodgkin's lymphomas**

The overall expression of Bmi-1 was 84.6% in T- and T/NK-cell lymphomas. Bmi-1 was expressed in all subtypes, ranging from 66.7% in adult T-cell leukemia/lymphoma (ATLL) and up to 100% in three subtypes: angioimmunoblastic T-cell lymphoma (AITL), cutaneous T-cell lymphoma

1 (CTCL) and anaplastic large cell lymphoma (Table 1). In all of the positive cases, Bmi-1 was  
2 expressed in more than 80% of the tumor cells. Moderate staining was noted in 37/78 cases (47.4%),  
3  
4 and strong staining in 17/78 cases (21.8%), compared to the weaker staining in the normal CD3+,  
5  
6 CD4+ and CD56+ cells in RLH and skin (Table1, Figures 2, S1 and S2).  
7

8 Ezh2 expression was observed in all T- and T/NK-cell lymphoma subtypes, ranging from  
9  
10 66.7% in AITL to 100% in CTCL (Table 1). A moderate staining intensity in these neoplasms was  
11  
12 noted, which was in contrast to almost a complete lack of expression of Ezh2 in normal CD3+, CD4+  
13  
14 and CD56+ cells in RLH and skin (Figures 2, S1 and S2). Among the positive cases, the highest  
15  
16 percentage of positive tumor cells was in T-LBL (90%) and the lowest was in CTCL (40%). In mature  
17  
18 T- and T/NK-cell lymphomas, a significant overexpression of both proteins compared to  
19  
20 interfollicular, follicular and cutaneous CD3+ T-cells, as well as CD56+ NK- cells, was detected  
21  
22 ( $X^2=13.075$ ,  $P=0.007$  for Bmi-1 and  $X^2=38.942$ ,  $P=0.000$  for Ezh2).  
23  
24

### 29 **Significant differences in Ezh2, but not Bmi-1 expression between high- and low-grade B-cell** 30 **neoplasms** 31

32 High expression levels of Ezh2 were found mainly in the aggressive variants of B-cell  
33  
34 neoplasms while Bmi-1 was highly expressed in all subtypes with no noticeable difference among  
35  
36 them (Figure 3A). The Chi squared test for Ezh2 showed a significant difference among the  
37  
38 subgroups of B-cell lymphomas ( $X^2 = 37.561$ ,  $P = 0.000$ ), and a one-way ANOVA with the Bonferroni  
39  
40 correction revealed that there were significant differences between the aggressive subtypes (BL,  
41  
42 DLBCL-GCB, DLBCL non-GCB and FLG3) and the indolent subtypes (FLG1-2, PC, PCM, LPL,  
43  
44 CLL/SLL and MALT lymphoma) (*mean difference = 1.06~2.31*,  $P = 0.000~0.030$ ). This difference  
45  
46 corresponded to the differences in the Ki67 index (*mean difference = 0.56~1.00*,  $P = 0.000~0.018$ )  
47  
48 among these subtypes (Table 2). The Chi squared test for Bmi-1 showed a difference in the expression  
49  
50 among the subtypes of B-cell lymphomas ( $X^2 = 99.257$ ,  $P = 0.000$ ). However, a one-way ANOVA  
51  
52 with the Bonferroni correction detected a single statistically significant difference, between BL and  
53  
54 MALT lymphoma (*mean difference = -1.38*,  $P = 0.004$ ) (Table 2). No statistically significant  
55

65

1 differences were detected among the subtypes of T/NK-cell lymphomas with regard to the expression  
2 of Bmi-1, Ezh2 and Ki67 (Figure 3B and Table S3).  
3  
4  
5

### 6 **Ezh2 expression correlated with the proliferative activity**

7  
8 The Ki67 labeling index showed a strong positive correlation with Ezh2 expression in B-cell  
9 neoplasms (*correlation coefficient (Co) = 0.983, P = 0.000*) and a considerable correlation in T- and  
10 T/NK-cell lymphomas (*Co = 0.629, P = 0.000*). This correlation was not detected in the case of Bmi-  
11 1 (*Co=-0.224, P=0.121*) in B-cell neoplasms, or (*Co=-0.251, P=0.146*) in T- and T/NK-cell  
12 lymphomas (Figure 4A). Fluorescent immunohistochemical staining of Ezh2 and Ki67 in DLBCL  
13 showed that almost all cells strongly co-expressed Ezh2 and Ki67. A low Ki67 proliferation index was  
14 observed in MALT lymphoma, which closely correlated with a low expression of Ezh2 (Figure 4B,  
15 white arrowhead). A few cells were stained weakly for Ki67 and Ezh2 (yellow arrowhead). Some  
16 cells showed intracellular co-localization of Ezh2 and Ki67 (red arrowhead). Fluorescent  
17 immunohistochemical staining revealed that the expression of Ezh2 closely correlated with that of  
18 Ki67 in almost all cells in B-cell lymphoma, in accordance with the correlation analysis (Figures 4A  
19 and B).

### 38 **Expression of Mel-18 in RLH and malignant lymphomas**

39  
40 Immunohistochemical staining revealed low expression of Mel-18 in RLH. Double staining  
41 with CD20 revealed only a few double positive cells in the germinal center and mantle zones. The  
42 same pattern was detected in the interfollicular areas, and double staining with CD3 revealed a few  
43 double positive cells. CD138+ plasma cells and CD56+ NK/T cells were both generally negative for  
44 Mel-18 (Table 3 and Figure 5). **The normal stratified squamous epithelium covering the tonsils**  
45 **showed nuclear and cytoplasmic staining in both the basal and superficial layers (Figure S3).**  
46  
47  
48  
49  
50  
51  
52

53 Mel-18 was expressed in 14.7% of B-cell neoplasms. DLBCL-GCB, DLBCL non-GCB,  
54 FLG1-2, PCM and PC all showed weak expression in 16.7% of cases. MALT lymphoma showed  
55 weak expression in 10% of cases. In T/NK-cell neoplasms, Mel-18 was expressed in 20% of cases.  
56 Both NK/T lymphoma and ALCL expressed Mel-18 in 33.4% of cases. T-LBL and ATLL showed  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 expression in 16.7% of cases while PTCL was negative in all cases. The staining intensity was  
2 typically weak, and the percentage of positive tumor cells was generally below 40% in the positive  
3 cases. Mel-18 was expressed weakly in 11/ 64 non-Hodgkin's lymphomas (Table 3 and Figure 5). Co-  
4 expression of Mel-18 and Bmi-1 was observed in 10 lymphoma cases. It is worth mentioning that one  
5 case of DLBCL-non GCB showed moderate staining for Mel-18 in 80% of tumor cells, and this case  
6 was Bmi-1 negative.

### 16 **Expression of Ezh2, Bmi-1 and Mel-18 in hematopoietic cell lines**

17 Normal resting PBMCs and CD4<sup>+</sup> cells were negative for Ezh2 and Mel-18 while the  
18 expression of Bmi-1 varied a little; a faint signal was observed in PBMC#1 and normal NK cells. The  
19 expression of the three proteins was not stable in PBMCs; stimulation of normal T-cells with  
20 CD3/CD28 immunobeads induced a weak expression of all three proteins (Figure 6C). Human  
21 mesenchymal stem cells (hMSCs) showed a strong expression of both Bmi-1 and Ezh2 and a weak  
22 expression of Mel-18. Lymphoma cell lines showed higher levels of both Bmi-1 and Ezh2 proteins  
23 compared to normal PBMCs. Mel-18 showed weak or no expression in B-cell lymphoma cell lines  
24 and T/NK lymphoma/leukemia cells compared to the high expression of Bmi-1. HTLV-1  
25 immortalized cell lines (IWA1, MT4 and MT2) showed enhanced expression of Bmi-1, Mel-18 and  
26 Ezh2 proteins compared to PBMCs and normal CD4<sup>+</sup> cells. The ratio of Bmi-1/Mel-18 was  
27 comparable in normal PBMCs and HTLV-I-immortalized cell lines; on the other hand, this ratio  
28 noticeably increased in malignant lymphoma cell lines (Figures 6A and B).

42  
43  
44

45 Immunofluorescent staining showed that normal resting PBMCs were negative for Ezh2, and  
46 a small population was weakly positive for Bmi-1. Immunofluorescent staining of several B and  
47 T/NK- lymphoma cell lines confirmed the higher expression levels of both proteins compared to those  
48 in normal PBMCs (Figure S4).

55

### 56 **Discussion**

57 The expression profile of Bmi-1 and Ezh2 in normal lymphoid tissues was mutually exclusive.  
58 Bmi-1 was expressed in the resting cells of the mantle zone, interfollicular T- zone and small  
59  
60  
61  
62  
63  
64  
65

1 percentage of plasma cells while Ezh2 was expressed in the proliferating cells of the germinal center.  
2 In the thymus, Ezh2 expression predominated in the cortex while Bmi-1 predominated in the  
3 differentiated cells of the medulla. This is consistent with the findings of previous reports [29-32].  
4 Mel-18 expression in RLH was generally low, which is also consistent with previous reports [33].  
5  
6

7  
8  
9 The present study showed that Bmi-1 is highly expressed in all subtypes of both B- and T-  
10 cell lymphomas, including the indolent types: MALT lymphoma, PC, PCM, LPL and CLL/SLL. Bmi-  
11 1 was previously reported to be preferentially expressed in aggressive B-cell lymphoma (DLBCL and  
12 BL) but not in indolent subtypes (FL and CLL/SLL) [34]. In the case of FL, the present study showed  
13 that Bmi-1 positivity is highly heterogeneous and dependent on each patient specimen; this might be  
14 due to differences in the patient populations (Table 1). No significant differences in the expression  
15 level of Bmi-1 were found in different grades of FL in the present study, suggesting that the  
16 expression of Bmi-1 does not contribute to the progression from low to high grade FL. Bmi-1 was  
17 reported to be one of the genes showing the signature of activated B-cell (ABC) type DLBCL, and  
18 could be used to distinguish it from the GCB type by a cDNA microarray analysis, and was therefore  
19 considered to be associated with a poor prognosis [35]. Later reports based on the  
20 immunohistochemical analyses showed that Bmi-1 expression was not restricted to the ABC type [14].  
21  
22 The present study showed that both GCB and non-GCB types expressed Bmi-1 with no significant  
23 difference noted between the subtypes (Tables 1 and 2), suggesting that the earlier differences might  
24 have been due to the differences between protein and mRNA expression since they are not always  
25 consistent. In this study, enhanced expression of Bmi-1 compared to the normal counterpart samples  
26 was found in some subtypes of lymphomas: BL, DLBCL-GCB, FLG1-3, PC, PCM and T-cell  
27 lymphomas ( $P=0.002\sim0.033$ ). This is consistent with reports that Bmi-1 transgenic mice developed  
28 lymphoma, and that Bmi-1 is a negative regulator of the INK4a-ARF locus, which encodes tumor  
29 suppressor proteins p16<sup>Ink4a</sup>, p19<sup>Arf</sup> and p15<sup>Ink4b</sup> [13, 36].

Meanwhile, Ezh2 showed a different expression profile in malignant lymphomas. The present study showed that Ezh2 expression was significantly stronger in the aggressive types of B-cell neoplasms (BL, DLBCL and FLG3) than the indolent subtypes (FLG1-2, SLL, LPL, PC, PCM and MALT lymphoma) ( $P = 0.000\sim0.030$ ) (Table 2). The Ezh2 positivity in FLG3 was higher than that in

FLG1-2. In T/NK-cell lymphomas, Ezh2 showed high expression compared to the negativity observed in normal counterpart samples ( $X^2=38.942$ ,  $P=0.000$ ). However, no significant difference among subtypes was noted, which could be explained by the fact that most T/NK-cell lymphomas were aggressive with a high Ki67 proliferation index (Table 1). This was supported by the strong positive correlation between Ki67 and the Ezh2 expression in B-cell lymphoma ( $Co = 0.983$ ,  $P=0.000$ ) and the considerable correlation in T-cell lymphoma ( $Co = 0.629$ ,  $P = 0.000$ ) (Figure 4A). This is consistent with previous reports that Ezh2 overexpression is associated with increased proliferation, metastasis and poor prognosis in breast, prostate and stomach cancers [18-20]. These findings suggest that Ezh2 overexpression is also associated with the proliferation and aggressiveness in lymphoma.

It has been reported that Bmi-1 and other members of PRC1 function downstream of PRC2 [7, 8]. However, the present study showed that there are different expression patterns of Bmi-1 and Ezh2. These proteins do not always co-localize in RLH and malignant lymphomas indicating that, at least in some situations, they function independently. This is supported by evidence that there are genes targeted by PRC2 that lack the product of PRC1 catalysis (H2AK119ub), and genes targeted by PRC1 in the absence of PRC2 [37, 38].

McCabe et al reported that GSK126 is a potent and highly selective inhibitor of Ezh2 methyltransferase activity that decreased the global H3K27me3 level and induced pharmacological inhibition of the proliferation in Ezh2 mutant lymphoma. GSK126 also reduced the H3K27me3 levels in wild-type DLBCL cell lines [39]. In view of the low expression of Ezh2 in normal resting populations, selective pharmacological intervention to inhibit Ezh2 activity in both wild type and mutant lymphomas is a promising approach that warrants further research.

Mel-18 expression was previously reported in several normal adult tissues [15-17]. In RLH, we found that few cells expressed Mel-18 with moderate intensity while some populations expressed Bmi-1 with weak to moderate intensity, especially in the mantle zone. In B- and T/NK-cell neoplasms, Bmi-1 expression was found in 158/187 (84.5%) of cases, and the staining intensity was mostly moderate (109 cases) to strong (26 cases) while Mel-18 was expressed weakly in 11/64 cases (17.1 %) of B- and T/NK cell neoplasms (Tables 1 and 3). The Western blot analysis revealed that both B- and

1 T/NK-cell lymphoma cell lines showed weak or no expression of Mel-18, in contrast to their  
2 moderate/strong expression of Bmi-1 while normal PBMCs were negative for Mel-18 and  
3 negative/faintly positive for Bmi-1 (Figure 6). The ratio of Bmi-1/Mel-18 (PRC1.4/PRC1.2) was  
4 comparable in normal PBMCs and HTLV-I-immortalized cell lines, and increased noticeably in  
5 malignant lymphoma cell lines. Together, these data suggest that the regulation of PRC1 in the normal  
6 lymphoid tissue is in favor of PRC1.4, rather than PRC1.2, and that the difference increases with the  
7 development of malignancy. Only PRC1.2 and PRC1.4 complexes have been shown to accumulate in  
8 H3K27me3-rich regions; they induce chromatin compaction and gene silencing in different targets,  
9 and are suggested to play a central role in PRC1 function [6]. The altered expression state may induce  
10 changes in the downstream gene targeting and expression in lymphomas.  
11  
12  
13  
14  
15  
16  
17  
18  
19  
20  
21

22 In conclusion, B-and T/NK- cell neoplasms show high expression of both Bmi-1 and Ezh2  
23 while maintaining low expression of Mel-18. The regulation of PRC1.2 and PRC1.4 shifts more  
24 towards PRC1.4 dominance in the neoplastic state. The coexpression of Bmi-1 and Ezh2 is a  
25 characteristic of the aggressive variants of these lymphomas. Ezh2 correlates with tumor proliferation,  
26 and can be used to distinguish proliferative/aggressive lymphoma variants from indolent ones and  
27 normal resting cell populations. A detailed understanding of the precise role(s) of these proteins in  
28 lymphomagenesis is still lacking. However, correlation between the expression status of Ezh2 and the  
29 Bmi-1/Mel-18 ratio with the patients' prognosis may provide a useful method for the pathological  
30 evaluation of lymphomas in the future.

(a) Bmi-1 expression was detected mainly in the mantle zone (MZ) while the germinal center (GC) was negative. (b) Ezh2 expression was detected in the GC while the MZ was negative (Insets show a higher magnification of the GC). (c) and (d) DLBCL-GCB-type was strongly positive for Bmi-1 and Ezh2, respectively. (e) and (f) Follicular lymphoma grade 3 was strongly positive for Bmi-1 and Ezh2, respectively. (g) and (h) Plasma cell myeloma was strongly positive for Bmi-1 and negative for Ezh2, respectively (a and b: Magnification x 200, inset x 400 and c to h: Magnification x400).

arrowheads show intracellular co-localization of Ezh2 and Ki67 (Magnification x400, Ezh2: red, Ki67: green).

**Fig. 5. Expression of Mel-18 in normal tonsil and malignant lymphomas**

(a) Few cells expressed Mel-18 in the germinal center and interfollicular zone of normal tonsils while the stratified squamous epithelial cells were positive (Inset from the germinal center showing one centroblast with moderate staining intensity for Mel-18) (b) Mucosa-associated lymphoid tissue (MALT) lymphoma showed a few cells with moderate staining intensity. (c) Diffuse large B-cell lymphoma showed a few cells weakly expressing Mel-18 (d) NK/T cell lymphoma showed a few cells weakly expressing Mel-18 (a: Magnification x100, inset: x400, b to d: Magnification x400).

**Fig. 6. Results of the Western blot analyses of Bmi-1, Ezh2 and Mel-18 expression in malignant lymphoma cell lines and normal control cells**

(A) Both Bmi-1 and Ezh2 were expressed in most B-cell lymphoma lines; however, Ezh2 showed a stronger signal in the more aggressive lymphoma lines. Mel-18 was negative in most B-cell lines  
(B) Both Bmi-1 and Ezh2 were expressed in most T-cell lymphoma lines. Mel-18 was weakly/faintly positive in ATLL leukemic cell lines (ED40515 and ATL55T). This was in contrast to HTLV-I immortalized cell lines (IWA1, MT4 and MT2), which showed an expression level comparable to that of Bmi-1. (C) Normal PBMCs#1 and normal NK cells showed a faint signal for Bmi-1 while they were negative for Ezh2 and Mel-18. Activated T-cells showed a faint expression of all three proteins. PBMCs#1 to #4: Peripheral blood mononuclear cells (PBMCs) from four healthy individuals, Activate T: T-cells activated with a CD3/CD28 cell expander and Norm NK: Normal natural killer (NK) cells.

One way ANOVA with Bonferroni correction, upper panel is the mean difference, \* and bold font indicate significant values (P < 0.05 level). BL: Burkitt lymphoma, DLBCL (GCB): Diffuse large cell B-cell lymphoma germinal centre type, DLBCL non GCB: Diffuse large B- cell lymphoma non germinal centre type, FLG3: Follicular lymphoma grade3, FLG1,2: Follicular lymphoma grade 1,2, MCL: Mantle cell lymphoma, CLL/SLL: Chronic lymphocytic leukaemia/small lymphocytic lymphoma, PCM: Plasma cell myeloma, PC: Plasmacytoma, LPL: Lymphoplasmacytic lymphoma, MALT: Mucosa associated lymphoid tissue

**Table 3. Expression of Mel-18 in RLH and malignant lymphomas**

Malignant lymphoma and normal control	Mel-18				Positive/ Total	Positivity %
	-	+	++	+++		
<b>DLBCL-GCB</b>	5	1	0	0	1/6	16.7%
<b>DLBCL non-GCB</b>	5	0	1	0	1/6	16.7%
<b>FLG1-2</b>	5	1	0	0	1/6	16.7%
<b>PCM and PC</b>	5	1	0	0	1/6	16.7%
<b>MALT lymphoma</b>	9	1	0	0	1/10	10%
<b>B-cell neoplasms</b>	29	4	1	0	5/34	14.7%
<b>T-LBL</b>	5	1	0	0	1/6	16.7%
<b>ATLL</b>	5	1	0	0	1/6	16.7%
<b>PTCL</b>	6	0	0	0	0/6	0%
<b>NK/T lymphoma</b>	4	2	0	0	2/6	33.4%
<b>ALCL</b>	4	2	0	0	2/6	33.4%
<b>T/NK-cell neoplasms</b>	19	5	0	0	6/30	20%
<b><u>RLH</u></b>						
<b>Mantle zone</b>	390	0	10	0	10/400	2.5%
<b>Germinal centre dark zone</b>	184	0	14	0	14/200	7%
<b>Germinal centre light zone</b>	195	0	5	0	2/200	2.5%
<b>CD 138 + plasma cells</b>	196	0	4	0	2/200	2%
<b>Interfollicular CD3 + cells</b>	192	0	8	0	8/200	4%
<b>CD56 + NK/T cells</b>	197	0	4	0	4/200	2%

Positivity includes (-), (+), (++) and (+++). DLBCL-GCB: Diffuse large cell B cell lymphoma germinal centre type, DLBCL non GCB: Diffuse large B- cell lymphoma non germinal centre type, FLG1-2: Follicular lymphoma grade 1-2, PCM: Plasma cell myeloma, PC: Plasmacytoma, MALT: Mucosa associated lymphoid tissue, T-LBL: T-cell lymphoblastic lymphoma, ATLL: Adult T-cell leukemia/ lymphoma, ALCL: Anaplastic large cell lymphoma, , PTCL: Peripheral T-cell lymphoma, NK/T: Natural killer/T-cell lymphoma, RLH : Reactive lymphoid hyperplasia. Data from RLH are based on cell count.
