**Essays in Exchange Rate Economics**

**Muammer Reza Bin Wali**

This thesis is presented for the Degree of  
Doctor of Philosophy  
of  
Curtin University

**December 2014**

Dedicated to  
my family , Syeda Nasreen Jahan, Sahil Muammer Wally and Syeda Naomi Tasnim  
whose support and sacrifices gave me confidence to reach at this stage.

## **Declaration**

To the best of my knowledge and belief this thesis contains no material previously published by any other person except where due acknowledgement has been made.

This thesis contains no material which has been accepted for the award of any other degree or diploma in any university.

Signature: \_\_\_\_\_

Date: \_\_\_\_\_

## **Acknowledgment**

I incurred debts to many individuals, without whose generous assistances and unfailing supports it would not have been possible to complete this dissertation. I would like to record my sincere gratitude to them.

First of all, I am greatly indebted to my supervisors Assoc Professor Meher Manzur and Assoc Professor Felix Chan. Their constructive guidance, valuable advice, and seriousness in academic research helped me in dealing with such controversial, complex and difficult issues as I have in this thesis. Their timely advice and critical comments greatly improved the quality of this dissertation. The experience I gained from working with them has contributed greatly to my professional and personal development.

My special thanks to Professor Jeffrey Petchey and Professor Helen Cabalu who were supportive and cooperative in their capacity as heads of the School of Economics and Finance towards completion of this thesis. I would also like to thank Sian Flynnne and other colleagues in my School for administrative help and support.

I like to express my deepest gratitude to my family, especially to my wife Deepa for her love and support, our son Sahil and my sister-in-law Prithula, who missed me during my busy days of dissertation writing, without their cooperation and sacrifice, this study would have taken much longer time to complete.

Finally, distant support and encouragement from my parents kept me on track and their faith and belief surely helped me a lot to reach here.

## **Abstract**

This research analyses the key issues in exchange rate economics. It provides a systematic treatment of exchange rate volatility and its manifestations; the presence of nonlinearity in exchange rates; and the interaction between national price levels and exchange rates. The approach is broadly empirical and applies recent econometric and modelling techniques to a wide range of up-to-date data on the major as well as developing countries. The issues covered in this study are among the most controversial in international finance. They raise questions about the degree to which domestic inflationary propensities and their transmission across countries are conditioned by the nature of the exchange rate regimes. These questions themselves concern the more fundamental problems of exchange rate determination, the degree of monetary independence and its implications for macroeconomic policy. This research aims to formally examine these issues with the specific objective of making original and substantial contribution to knowledge. Specifically, the results of this study is expected to contribute to an understanding of the intriguing questions regarding the nature and extent of exchange rate volatility; the role of nonlinearity, outlier and structural change in exchange rate returns; and the link between the exchange rate instability and domestic inflation.

Chapter 1 sets the stage for the other chapters in this thesis to follow. The broad features of major exchange rates since the early 1970s, and a comparison of these features with those of the 1960s are the subject of Chapter 2. Also included in this chapter is an analysis of whether these features are manifested in real interest rates and in commodity prices. The results indicate that exchange rates are not as volatile as widely perceived.

A systematic analysis is conducted in Chapter 3 regarding the time series properties of a mixed bundle of currencies since major currencies returned to the floating system in the early 1970s. The sample includes all major currencies and several other relatively less liquid currencies, all denominated in British pound-sterling. The purpose of including relatively less liquid currencies is to examine if nonlinearity is more of a phenomenon for the currencies of less-developed countries. The results indicate the presence of nonlinearity in exchange rates. However, the outliers and structural breaks are not found to be significant in affecting the results.

Chapter 4 provides an empirical re-examination of the purchasing power parity (PPP) theory for a mixed bundle of currencies using panel data techniques. Alternative panel unit root tests are implemented with the British pound sterling (GBP) as the numeraire currency. Results are then compared with a U.S. dollar-based panel. The panel unit root tests failed to provide support for PPP. The data are then analysed using alternative panel cointegration tests. The idea is that, non-rejection of unit roots in the real exchange rates does not necessarily imply a rejection of PPP. If nominal exchange rates and relative price levels are integrated of order one (in levels), then it is possible that these two variables may be cointegrated, implying a close relationship in the long run. Again, the results are not encouraging for PPP. The sample is then divided into 3 sub-group of countries to check if the results are sensitive to country characteristics. The results are mixed and the data tend to reject PPP.

Chapter 5 provides a further check on the results in Chapter 4, this time using a Divisia index approach. This approach has a similarity with the panel approach in the previous chapter in that it provides a test of PPP based on several countries jointly, rather than taking pairs of countries in isolation from the rest of the world. Using this framework, the short-run results indicate that the predictions of PPP do not hold up well. On the other hand, the long-run data are quite consistent with the PPP hypothesis. The results identify five years as a broad measure of the length of the long run in so far as PPP is concerned. Chapter 6 concludes the thesis.

# **Chapter 1**

## **Introduction**

---

### **1.1 Aims and Background**

This research analyses the key issues in exchange rate economics. It provides a systematic treatment of exchange rate volatility and its manifestations; the presence of nonlinearity in exchange rates; and the interaction between national price levels and exchange rates. The approach is broadly empirical and applies appropriate econometric and modelling techniques to a wide range of up-to-date data on the major as well as developing countries. The issues covered in this study are among the most controversial in international finance. They raise questions about the degree to which domestic inflationary propensities and their transmission across countries are conditioned by the nature of the exchange rate regimes. These questions themselves concern the more fundamental problems of exchange rate determination, the degree of monetary independence and its implications for macroeconomic policy. This research aims to formally examine these issues with the specific objective of making original and substantial contribution to knowledge. Specifically, the results of this study, as indicated in Section 1.3, is expected to contribute to an understanding of the intriguing questions regarding the nature of exchange rate dynamics; the role of nonlinearity, outlier and structural change in exchange rate returns; and the link between the exchange rate instability and domestic inflation.

This chapter sets the stage for the other chapters in this thesis to follow. In the rest of this chapter, a skeletal background is provided, followed by some stylised facts, and an overview of other chapters in this thesis. All chapters are self-contained and consequently, the background material in this chapter is kept short to minimise duplication of material in other chapters. The whole thesis is written in such a way that specialists in international finance can skip this chapter without loss of continuity.

An exchange rate is the international value of a country's domestic currency. In an open-economy world, this value affects household purchasing power and corporate financial decision-making, which in turn, would influence global trade and capital flow patterns. Chen (2014) argued that, understanding exchange rate behaviour and its macroeconomic policy implications have historically occupied the centre stage of

research in international finance. The last decade or so has seen important theoretical and empirical advances in this area, but the ongoing puzzles concerning exchange rate determination and related issues and ramifications still persist. The recent economic turbulence triggered by sovereign debt crises in the euro zone, preceded by the global financial crisis, give further evidence to the importance of having a clear understanding of exchange rate behaviour, Taylor and Manzur 2013 argued that there remains many important but unresolved theoretical and empirical questions on exchange rate.

Following the break-down of the Bretton-Woods system in early 1970s, the behaviour of exchange rates has changed dramatically (see Wali and Manzur, 2013). The ‘collapse’ of the purchasing power parity (PPP), as reported by Frenkel (1981), followed by Meese and Rogoff’s (1983) important result that a simple random walk model outperforms most of the time-series and structural exchange rate models, presented new challenges in appreciating the complexity behind the exchange rate dynamics. Several interesting approaches have recently been developed to study a host of important issues including, for example, the connection between economic fundamentals and exchange rates, the purchasing power parity (PPP) puzzle, the expenditure-switching effects of exchange rate movements, the output and welfare effects of alternative exchange rate regimes, the short-run versus long-run influences in exchange rates and so on.

On the theoretical side, two major developments figure prominently. The first is what is now widely known as the new open economy macroeconomics (NOEM), pioneered by Obstfeld and Rogoff (1995). NOEM emphasises the normative implications of alternative international monetary regimes, and gives an integrative treatment of exchange rates, output and the current account in a dynamic general equilibrium framework. While the approach is theoretically quite developed, its empirical implementation is still at an early stage, and would require considerable further development (see Justiniano and Preston, 2010, for a recent empirical contribution). The second major theoretical development is the extension of the present-value models of exchange rates to world commodity prices, initiated by Chen and Rogoff (2003), and Chen et al. (2010). In this framework, the exchange rate is determined in a forward-looking manner (like all other asset prices, such as stocks,

bonds and so on), and the current spot rate is equal to the discounted sum of its expected future value of the economic fundamentals. As world commodity prices are part of the economic fundamentals, changes in world commodity prices are essentially exogenous to those in the exchange rates and consequently, serve as clear and identifiable terms-of-trade shocks to these exchange rates (see Chen et al., 2010).

Recent advances in empirical research far outstrip their theoretical counterparts. Accelerated computer power, increased availability of high quality data, and the development and adaptation of more sophisticated econometric procedures have seen an enormous increase in the empirical exchange rate literature. To circumvent the power problem of the traditional tests, long-span studies and panel data methodologies are introduced (see, for a survey, Taylor and Manzur, 2013). Here, the basic idea is to utilise the cross section dimension to increase the power of the unit root test. Under certain conditions, the increase in the cross section dimension is equivalent to adding more information per unit of time and thus improves the power of the test.

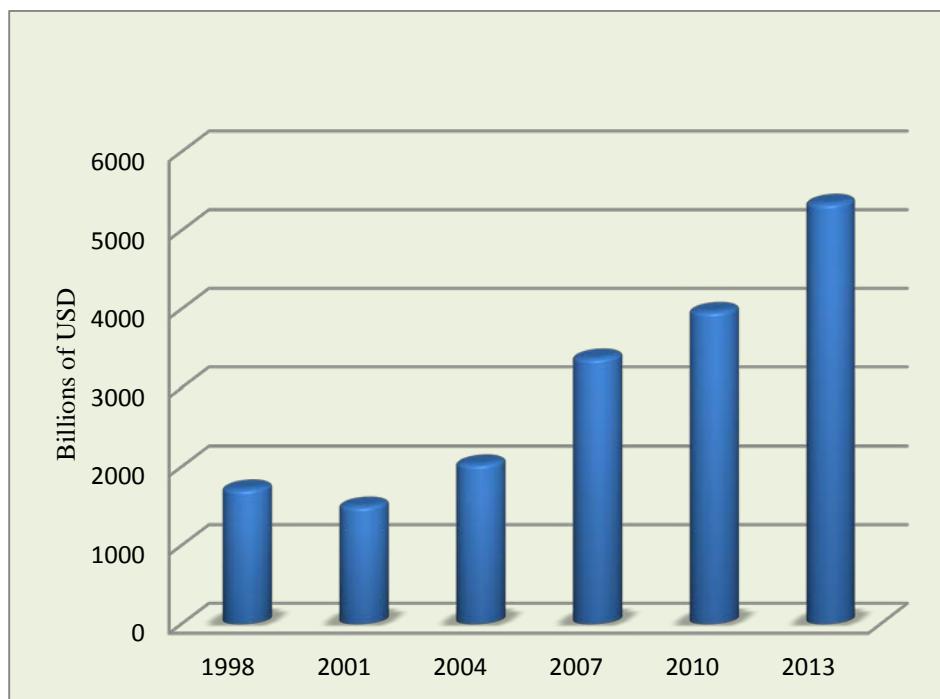

There has been a tsunami of interest in nonlinear modelling of exchange rate volatility. Since Engle (1982), many different modelling approaches have been applied to volatility forecasting. Many of these models are surveyed in Bollerslev et al, (1994) and subsequently, Engle (2002a; 2002b), among others. These models allow for nonlinearity, asymmetry and long memory properties of volatility in returns that can be non-normal with a variety of parametric and nonparametric distributions (Engle, 2004). In general, most studies detect the presence of nonlinear dependencies in exchange rate returns series. Interestingly, PPP figures prominently in the research in nonlinear dynamics of exchange rates (see such as, Cuestas and Mourelle (2011), Kim and Moh, (2010), Yoon (2010), Sollis (2008), Villavicencio (2008)).

Significant theoretical and empirical advances notwithstanding, the properties and dimensions of exchange rate volatility are still far from fully understood and needs considerable new work. Empirical applications and evidence provided in this study would make useful contributions towards filling the gaps in the existing literature. While the history of exchange rate is interesting, it is also long and complicated and it is not the focus of the thesis. Interested readers can refer to Frankel and Harry (2013) or Edward, S.,(2003) for details.

## 1.2 Some Stylized Facts

Currency trading (measured in dollar terms) constitutes the largest financial market in the world with a phenomenal growth rate. In its 2013 Triennial Central Bank Survey, the Bank for International Settlements reports that global trading volume in foreign exchange markets averaged \$5.3 trillion each day. As can be seen in figure 1.1, this is more than twice the volume of currency that was traded just a decade ago. As growth in currency trading accelerates with increased globalisation, there is an increased need for a proper understanding of the currency behaviour.

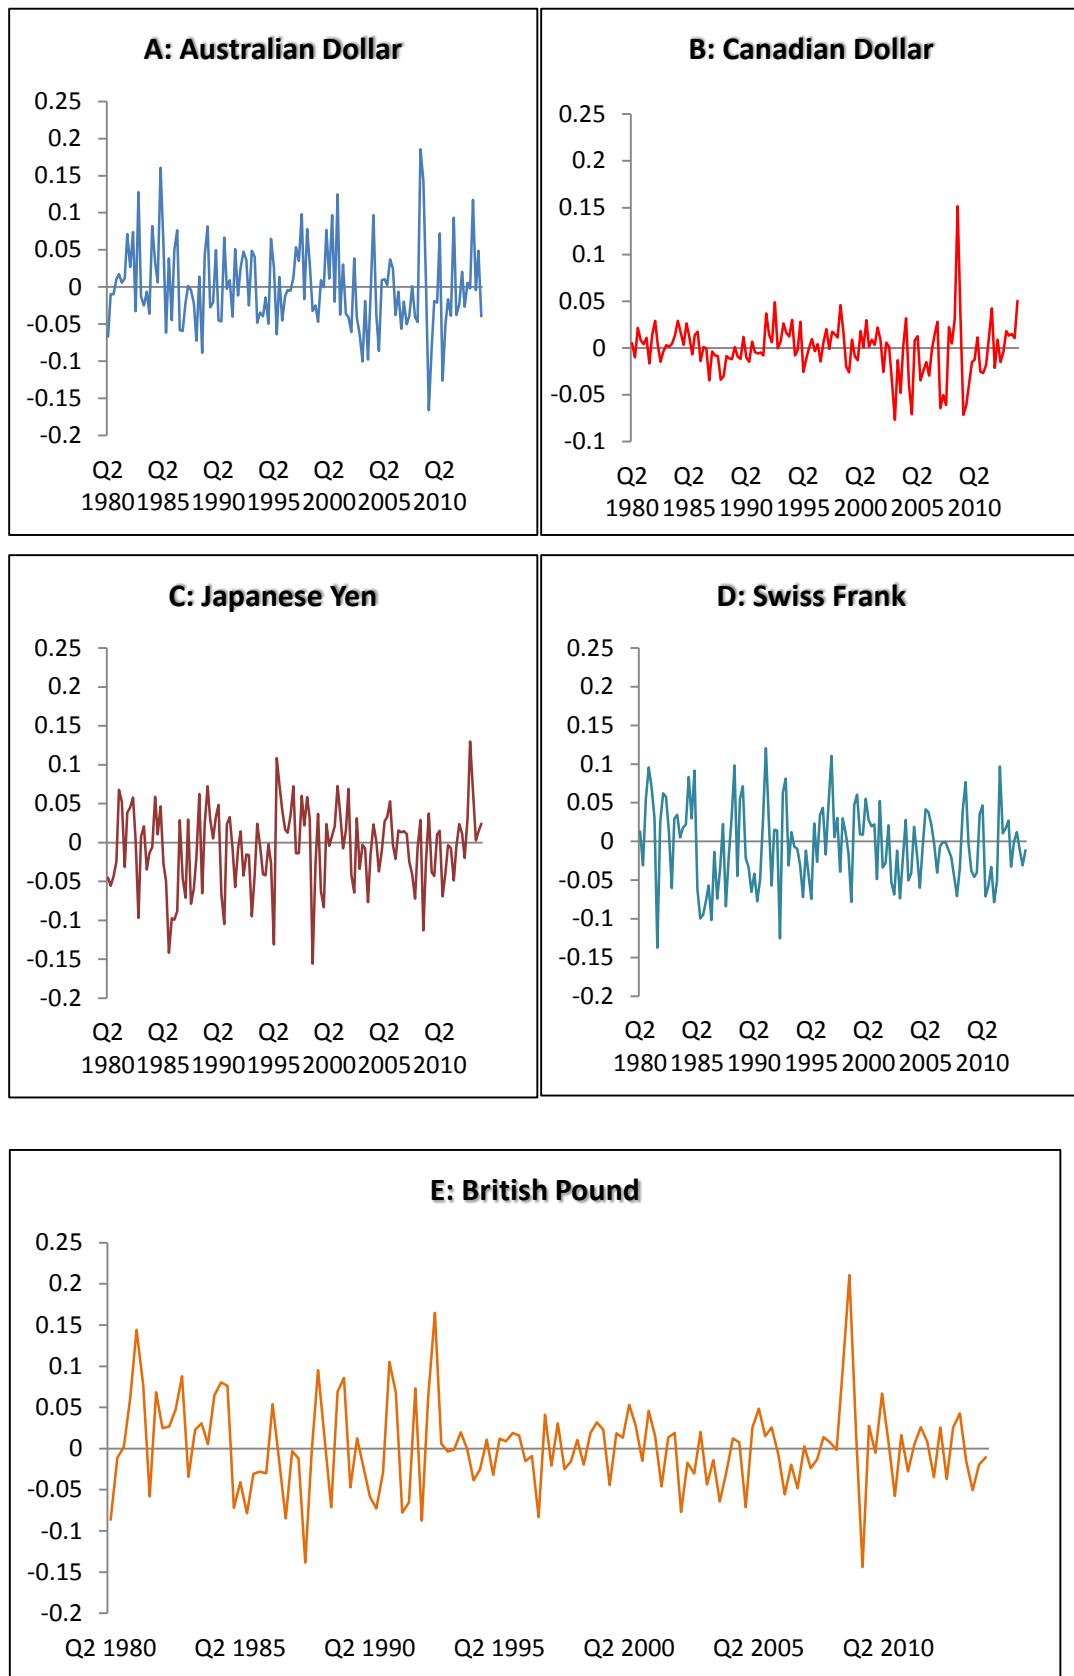

**Figure 1.1: Global foreign exchange market turnover**

Source: BIS Triennial Central Bank Survey 2013

Figure 1.2 gives the time-series plots of nominal exchange rates (in log-changes  $\times 100$ ) of five major currencies, namely, Australian dollar, Canadian dollar, Japanese yen, Swiss franc and the British pound sterling, all denominated in the U.S. dollar. The choice of log-difference as measurement of returns is consistent with the

**Figure 1.2: Exchange rate log-change:  
5 major currencies, 1980(Q1)-2014(Q1)**

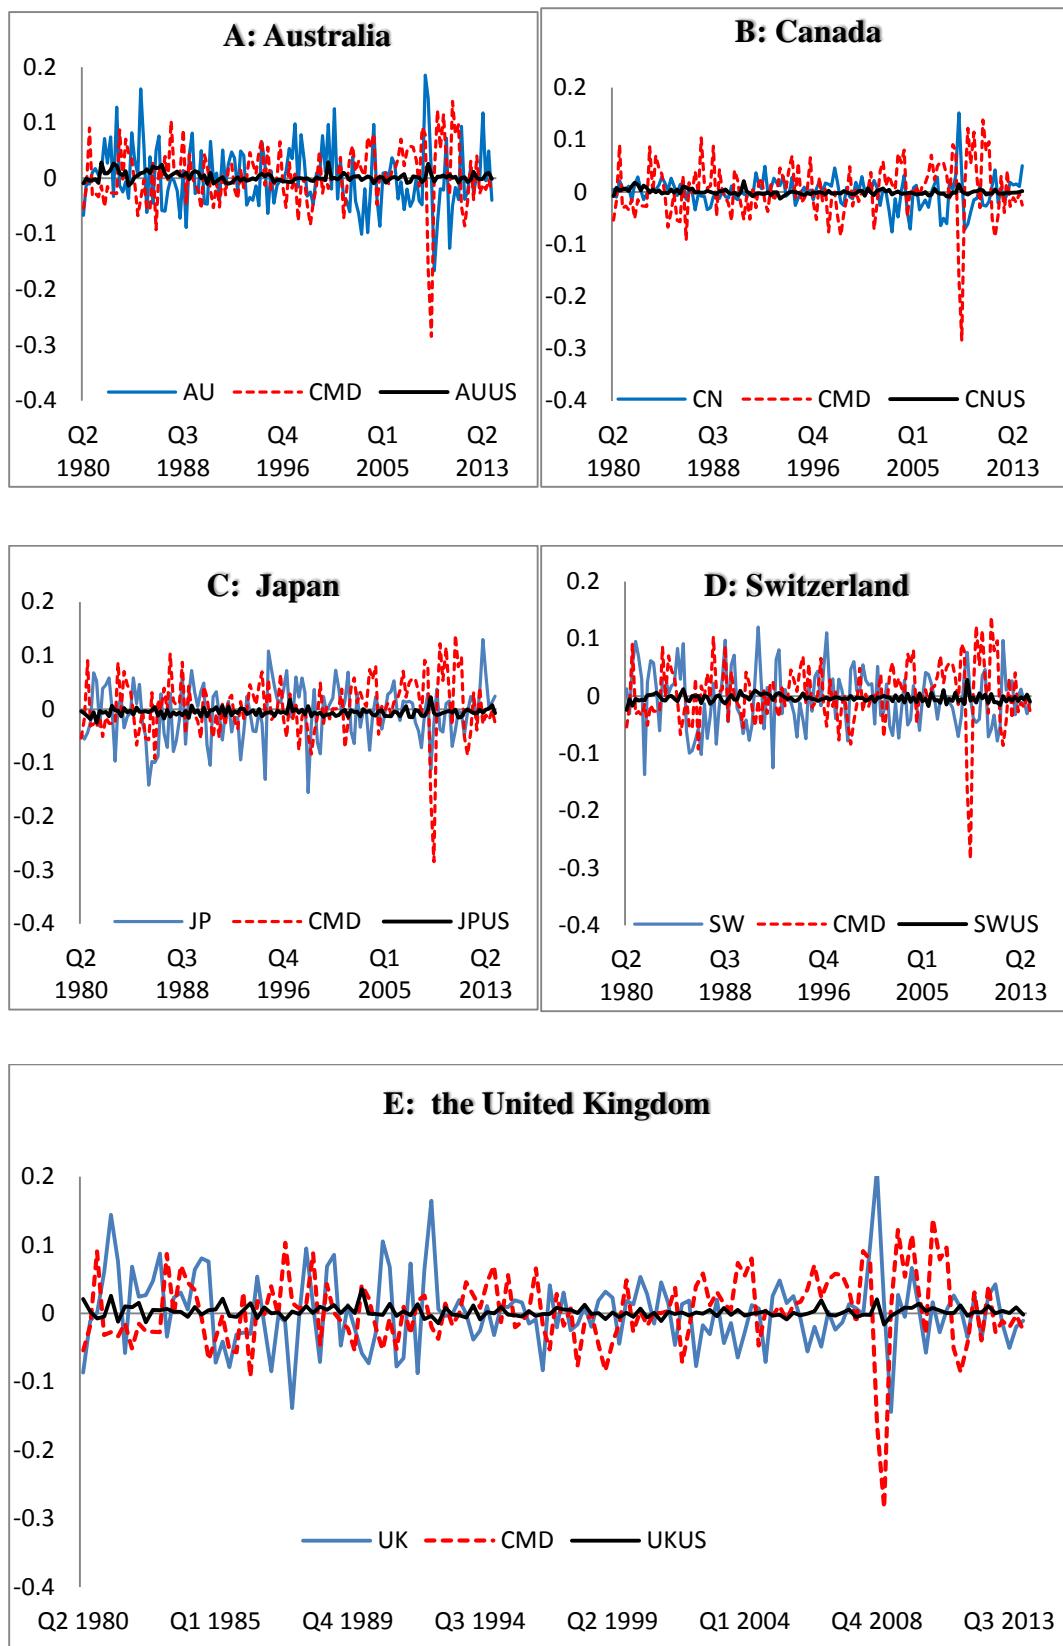

literature and the results presented here remain robust using the alternative measure such as percentage change. The data are quarterly and for the period 1980 (Q1) - 2014 (Q1). All data are from International Monetary Fund's (IMF) 'International Financial Statistics' (IFS) through DataStream and appended at the end of this chapter. As can be seen, the quarterly swings in the Australian dollar have been larger in amplitude compared to those in the Canadian dollar over the entire sample period. It can also be seen that Japanese yen, Swiss franc and British pound sterling are equally volatile with a tendency for the British pound sterling to slightly dominate. In all cases, the swings tended to have peaked during 2007-2008 – a period that coincides with the start of the global financial crisis.

For a *prima facie* comparison, exchange rate data for these five countries (as in Figure 1.2) are plotted with the inflation differential (domestic inflation minus the US inflation) and world commodity prices, as in Figure 1.3. CPI is used to measure inflation and Commodity Research Bureau (CRB) spot world commodity price index is used for commodity prices. Again all data are from IMF's IFS through DataStream and appended at the end of this chapter. Figure 1.3 is done for each country individually. As can be seen, exchange rates and commodity prices reflect some similarity in their quarterly oscillations, but the variability in relative inflation is considerably smaller. Thus, Figure 1.3 reveals little (if any) relationship between exchange rates and national inflation levels. Given the stationary nature of the returns, the unconditional mean can be interpreted as the long run change. This long-run, or underlying, change broadly approximates the inflation differential in Figure 1.3. This idea derives from PPP which is the subject of considerable investigation in the chapters to follow.

### **1.3 A Preview of Other Chapters**

Chapter 2 describes the broad features of major exchange rates since the early 1970s, and compares these features with those of the 1960s. Also included is an analysis of whether these features are manifested in real interest rates and in commodity prices. The results indicate that exchange rates are not as volatile as they are generally viewed. This chapter is based on Wali and Manzur (2013).

**Figure 1.3: Exchange rate, inflation differential and commodity price index:  
5 major countries 1980(Q1)-2014(Q1)**

Chapter 3 gives a systematic treatment of the time series properties of a mixed bundle of currencies since major currencies returned to the floating system in the early 1970s. The sample includes four major currencies and eight other relatively less-liquid currencies, all denominated in British pound-sterling. The purpose of including relatively less liquid currencies is to compare and check if nonlinearity is more of a phenomenon for the currencies of less-developed countries. The results indicate the presence of nonlinearity in exchange rates. However, the outliers and structural breaks are not found to be significant in affecting the results. This chapter is based on Wali et al. (2014).

Chapter 4 provides a re-examination of the empirical content of PPP for a mixed bundle of 12 currencies using panel data techniques. Alternative panel unit root tests are implemented with the British pound sterling (GBP) as the numeraire currency. Results are then compared with a U.S. dollar-based panel. The panel unit root tests failed to provide support to PPP. The data are then analysed using alternative panel cointegration tests. The reason for this further analysis is that non-rejection of unit roots in real exchange rates does not necessarily imply a rejection of PPP. If nominal exchange rates and relative price levels are integrated of order one (in levels), then it is possible that these two variables may be cointegrated, implying a close relationship in the long run. Again, the results are not encouraging for PPP. The sample of 12 countries is then divided into 3 sub-groups to check if the results are sensitive to country characteristics. The results are mixed and the data tend to reject PPP.

Chapter 5 provides a further check on the results in Chapter 4, this time using a Divisia index approach. This approach has a similarity with the panel approach in the previous chapter in that it provides a test of PPP based on several countries jointly, rather than taking pairs of countries in isolation from the rest of the world. Using this framework, the short-run results indicate that the predictions of PPP do not hold up well. On the other hand, the long-run data are quite consistent with the PPP hypothesis. The results also identify five years as a broad measure of the length of the long run in so far as PPP is concerned. Interestingly, the results in this chapter are at variance with those in previous chapter. This tends to be a puzzle. It could be a challenge to explain this puzzle. Chapter 6 concludes the thesis.

As can be seen from the above, this thesis takes a multidisciplinary approach to investigate the nature of exchange rate. As such, substantive literature review has been taken in each quantitative chapter to highlight the development in each separated but related approach to exchange economics; hence a separate chapter may induce unnecessarily repetition.

## Appendix to Chapter 1

This appendix contains exchange rate, commodity price index and price level differential data used in the analysis of this chapter. All data are quarterly and in log-change form. The numerarie currency is the U.S. dollar for all the exchange rates. The columns gicing the exchange rates in Table A1.1 are defined as: AU=Australia, CN=Canada, JP=Japan, SW= Switzerland, UK= British pound sterlign, CMD = commodity price index. The last 5 columns contain the price level differential data. It expresses difference between the log-change of domestic CPIs and the US CPI. For example, AUUS represents log-change of Australian CPI minus log-change of US CPI. The soft copies of the data are in excel files, available upon request.

## **Chapter 2**

### **Exchange Rate Manifestations**

---

#### **2.1 Introduction**

As alluded to in the previous chapter, exchange rates have been markedly volatile since switch to floating rates by major currencies in the early 1970s. Higher exchange rate volatility implies increased uncertainty for global business and finance, which can be enormously costly. In order to cope with this increased exchange rate volatility, economic managers have been constantly looking for alternative arrangements. The best example of a potential solution is the European Union whose member countries revoked use of their national currencies and adopted a single currency (the euro). A number of emerging economies have struggled with variants of managed exchanged rate regimes. Smaller countries like Panama and Ecuador have gone for dollarization; and other high-inflation countries like Mexico and Argentina are viewed as likely candidates for this option. Consequently, the issue of exchange rate volatility is of great concern for policymakers and business.

How volatile have real exchange rates been since a return to floating by the major currencies? Do other financial variables such as interest rates or commodity prices exhibit similar volatility? In this chapter, I provide a descriptive analysis of the broad features of major exchange rates since the early 1970s, and compare these with those of the 1960s. Also included is an analysis of whether these features are manifested in real interest rates and commodity prices. The purpose here is to describe the features rather than to explain them. A descriptive historical study is useful in abstracting a global picture corroborating the stylized facts that are fundamental to understanding the behaviour of exchange rates. These results have implications for several unresolved issues in exchange rate modelling, such as asymmetric exchange rate dependence (see, for example, Patton, 2006), financial risk management (see, for example, Christoffersen and Diebold, 2006), international trade and capital flows (see, for example, Kiyota and Urata, 2004), and the political economy of exchange rate regimes (see, among others, Willett, 2007; Wilson and Ng, 2007).

The chapter is organised as follows. The next section gives the details of the data used in this chapter. Section 2.3 contains a descriptive analysis of the exchange

rate data before and after the float. Exchange rate data are then compared with the corresponding real interest rates and commodity prices in Section 2.4, followed by a discussion on correlations in Section 2.5. The last section concludes the chapter. This chapter is based on Wali and Manzur (2013).

## 2. 2 Data

I use real rather than nominal exchange rates involving most major currencies, namely the Group of Seven (G-7) and the Australian dollar. The three European currencies in the G-7 (Italian lira, French franc and German mark) have been replaced by the Euro for post-2003 data. All exchange rates are denominated in the U.S. dollar. Real exchange rates are calculated as nominal rates (expressed as domestic currency costs of \$US1) multiplied by the ratio of the domestic price level to the US price level. The consumer price index (CPI) is used for prices. Harmonized CPI is used for Euro zone prices. All data are from DataStream, and are quarterly, starting from 1960:Q1 to 2014:Q1. For our purposes, data for the 1960s represent the experience of the fixed-exchange rate period. The sample for the flexible regime is further truncated into three sub-periods to allow for possible shocks that might have introduced structural breaks into the series. The first sub-period 1973:Q1–1986:Q2 witnessed a set of common shocks associated with sharp fluctuations in the price of oil and contractionary monetary policy in major industrial economies. The second sub-period, 1986:Q3–2003:Q4 represents the globalization period characterised by dramatic increases in the volume of cross-border trade in both goods and assets. The third sub-period 2004:Q1–2014:Q1 covers recent developments including the global financial crisis and sovereign debt problems in the Euro zone.

For commodity prices, I have used the Commodity Research Bureau (CRB) spot world commodity price index.<sup>1</sup> Note that, this index is a measure of price movements of a collection of sensitive basic commodities whose markets are presumed to be among the first to be influenced by changes in economic conditions. As such, it serves as one early indication of impending changes in business activity. So the volatility of the index can be used as the perfect substitute to the volatility of

---

<sup>1</sup> Back ground, description, estimation procedure and other detailed information on CRB spot index is available at [http://www.crbtrader.com/crbindex/spot\\_background.asp](http://www.crbtrader.com/crbindex/spot_background.asp).

the underlying commodities. Hence, it is no difference to consider share market index versus the firm stock price. The idea is to provide an overview on the market rather than just one particular commodity. Except for Japan during the 1960s, long-term government bond rates are used for nominal interest rates for the entire sample. For Japan, because of data unavailability, quarterly Treasury bill rates are used for the 1960s.<sup>2</sup> The data are appended at the end of this chapter.

### 2.3 Results

Table 2.1 contains descriptive statistics of quarterly log-changes of real exchange rates for the G-7 plus the Australian dollar before and after the float. The last column gives the means across currencies. A positive change is a real depreciation of the domestic currency against the U.S. dollar. Looking at mean changes for the 1960s, all these currencies had, on average, depreciated against the U.S. dollar. Similar results obtain for the full sample of the floating regime period (1973-2014), except for the Japanese yen, and the German mark, which, on average, had appreciated against the U.S. dollar. The mean changes for the sub-periods under the floating regime are slightly mixed, but on average, the value of the U.S. dollar has been in decline against these currencies from 1986 onwards. Interestingly, the mean quarterly change across all currencies for the entire floating rate sample (1973-2014) is not too far away from zero (.05, see the fifth entry from top in the last column of Table 2.1). This may have implications for the long-run adjustments of exchange rates to purchasing power parity (PPP). Manzur (1990) argued that, real exchange rate changes tend to persist on a quarter-to-quarter, bilateral basis, for an individual country, but they may wash away on a longer-term, multi-currency basis. Note that PPP, which postulates an equilibrium relationship between exchange rates and national price levels, is viewed as an anchor for exchange rate dynamics (Rogoff, 1996).

Looking at the standard deviation measures in Table 2.1, they have increased noticeably in the period 1973-2014 than in the 1960s for all currencies. The average

---

<sup>2</sup> Only long term bonds are available for all the countries and for the entire period under study. Other instruments like T-bills or other short term bonds are not available for all the countries and for the period 1960-2014.

Notes: \*, \*\* and \*\*\* represent 10%, 5% and 1% significance level, respectively. As the Australian dollar was floated in 1983, the data for Australia are adjusted accordingly for the sub-samples. Euro data for the period 1973-2014 starts from January 1999. Germany, Italy and France data finishes at December 1998. The last column gives the means across the rows. AU, CN, EUR, FRA, GER, ITA, JP, UK and US stands for Australia, Canada, Euro, France, Germany, Italy, Japan, the United Kingdom, and the United States respectively.

standard deviation of these four currencies is at least 2.5 times larger than that in the 1960s (see the last column of the table). Looking into the three sub-periods of the floating exchange rate system, the standard deviations for the first two sub-periods are more or less comparable, but have increased for each of these currencies except for the Japanese yen in the last sub-period. The reduction in variability of the yen in the last sub-period may not be the result of heavy interventions in the foreign

exchange market<sup>3</sup> by the Bank of Japan since early 1990s, but that cannot be ruled out (see, for example, Kim and Sheen, 2006). Overall, the results indicate that variability of real exchange rates has increased since exchange rates were set to float. This is consistent with the literature (see Mussa, 1987 and Manzur, 2003). Note that this result finds support in the asset approach to exchange rates, whereby exchange rates being asset prices adjust instantaneously to ‘news’, and consequently, increased variability under a floating regime can be viewed as a matter of rule, rather than exception (see Mussa 1982).

Table 2.1 also reports the skewness and kurtosis measures of real exchange rate changes as a check for their empirical distributions. Skewness is a measure of symmetrical distribution of a series, while the coefficient of kurtosis is informative of the tail behaviour of a series, both being issues that have drawn substantial interest in exchange rate economics (see, Bai and Ng, 2005, among others, for more details). As can be seen from the observed values of skewness, real exchange rate change distributions are approximately symmetric in all cases, except for the British pound sterling in the 1960s, and Australia in the last sub-period (2004-2012). In all cases except for those in the sub-period 1973-1986, the observed values of kurtosis exhibit a pronounced ‘fat-tailed’ property when compared to the normal. The Jarque-Bera (J-B) test (Jarque and Bera, 1980) statistic rejects the null of normality in most cases. Again, the perverse yen result may have implications for the Bank of Japan’s short-term control of the money supply with an external exchange rate objective since the move to floating exchange rates in 1973 (see, among others, Hutchison, 1988). As can be seen yen appreciated throughout the floating period. During that period Bank of Japan actively intervened in the foreign exchange market on a regular basis to keep the Yen value within a targeted range. Note that modelling leptokurtic behaviour of exchange rates has been among the active areas of research since the work of Engle (1982). See, for example, Hsieh (1988; 1989; and 1991), and more recently, Emekter et al. (2009), for empirical applications. While it is conventional to provide and compare density plots based on these histograms, this is not appropriate in this context

---

<sup>3</sup> Bank of Japan, in coordination with the Ministry of Finance, launched a reserve targeting program during that period and kept Japanese yen exchange rate at the targeted level by buying and selling yen in the foreign exchange market.

See notes to Table 2.1

since the focus is on the tails of exchange rate distributions. In this case, the density plots may potentially be misleading since there are not sufficient number of observations in the tails to construct robust density plots.

## 2.4 A Comparative Picture

For comparison purposes, I now turn to similar features of other financial variables such as commodity prices and real interest rates. The real interest rates are the nominal rates adjusted for inflation (ex-post). CPI is used to measure inflation. Note that changes in exchange rates and commodity prices are dimensionally consistently with ‘levels’ of real interest rates.

Table 2.2 is the real interest version of Table 2.1. As can be seen across the 1960s and the 1973-2014 period, the mean changes are somewhat comparable, but there are divergences in the standard deviations. The standard deviations of real interest rates for most of the countries in the sample have tended to decline, except for US (2.35 to 2.77) and the UK (4.22 to 5.31). Comparing the last column in Table 2.2 with the last column in Table 2.1, it can be seen that on average, the volatility of real interest rates tends to exceed that of exchange rates both under fixed and flexible exchange rate systems. Based on the observed values of skewness and kurtosis, the J-B test statistics reject the null of normality in most cases.

Table 2.3 reports results for world commodity prices. As can be seen, the mean changes are not wildly different from those for real exchange rates and real interest

**Table 2.3: Summary statistics of commodity price index (log-change):  
1960s vs post-float**

Period	Mean	SD	Skewness	Kurtosis	Jarque Berra
1960s:	0.24	2.68	0.31	2.59	0.9609
1973-2014:	0.79	5.74	-0.65	6.43	92.32*
1973-1986:	1.04	6.22	0.23	2.30	1.5574
1986-2003:	0.31	3.84	0.13	2.99	0.2076
2004-2014:	1.30	7.58	-1.57	7.45	50.51*

rates for all periods. The standard deviations indicate that world commodity prices are no less volatile than real exchange rates and real interest rates. Looking into the last sub-period, commodity prices tend to be more volatile than real exchange rates, but less so compared to real interest rates. J-B test statistics reject the null of normality for the full floating rate sample (1973-2014) and the last sub-period (2004-2014).

## 2.5. Correlations

Comparing the results in Table 2.1 with those in Tables 2.2 and 2.3, one may observe that it is not necessarily expected that the additional variability in real exchange rates in the post-float sub-period (simply as a consequence of the asset prices *vis-a-vis* national price levels) would necessarily carry over to commodity prices and interest rates. Can that possibility be ruled out? A crude way to handle this question is to examine correlations among these variables. Table 2.4 reports correlation coefficients across the four real exchange rates in pre- and post-float periods (Italy, France and Germany are dropped here for brevity). As can be seen correlations across the four currencies are either negative or close to zero in the 1960s. For 1973-2014, the coefficients are all positive and substantially larger as expected, except for the Japanese yen-Australian dollar and Japanese yen-Canadian dollar.

**Table 2.4: Correlation among the currencies: 1960s vs post-float**

<b>1960s:</b>					<b>1973-2014:</b>				
	Australia	Canada	Japan	UK		Australia	Canada	Japan	UK
Australia	1.00				Australia	1.00			
Canada	-0.02	1.00			Canada	0.70	1.00		
Japan	0.06	-0.15	1.00		Japan	0.05	-0.01	1.00	
UK	-0.11	0.06	0.07	1.00	UK	0.51	0.48	0.32	1.00

---

Note: All the values are statistically significant.

Table 2.5 gives the correlations of changes in real exchange rates, real interest differentials (relative to the U.S. real interest rate) and commodity prices for 1973-2012 for these four countries. For each of the currencies, the real exchange rate tends to be either uncorrelated or negatively correlated with the real interest rate and commodity prices. However, the correlation coefficients of Australian and Canadian dollars with world commodity prices are both negative (a negative change is a real

**Table 2.5: Correlations of exchange rates, interest rates and commodity prices, 1973 – post-float**

Australia				Canada		
	Dollar	Interest rate	Commodity price	Dollar	Interest rate	Commodity price
Dollar	1.00			Dollar	1.00	
Interest rate	0.077	1.00		Interest rate	0.083	1.00
Commodity price	-0.339	-0.059	1.00	Commodity price	-0.327	-0.238
Japan				UK		
	Yen	Interest rate	Commodity price	Pound	Interest rate	Commodity price
Yen	1.00			Pound	1.00	
Interest rate	-0.007	1.00		Interest rate	0.042	1.00
Commodity price	0.023	0.018	1.00	Commodity price	-0.262	0.116

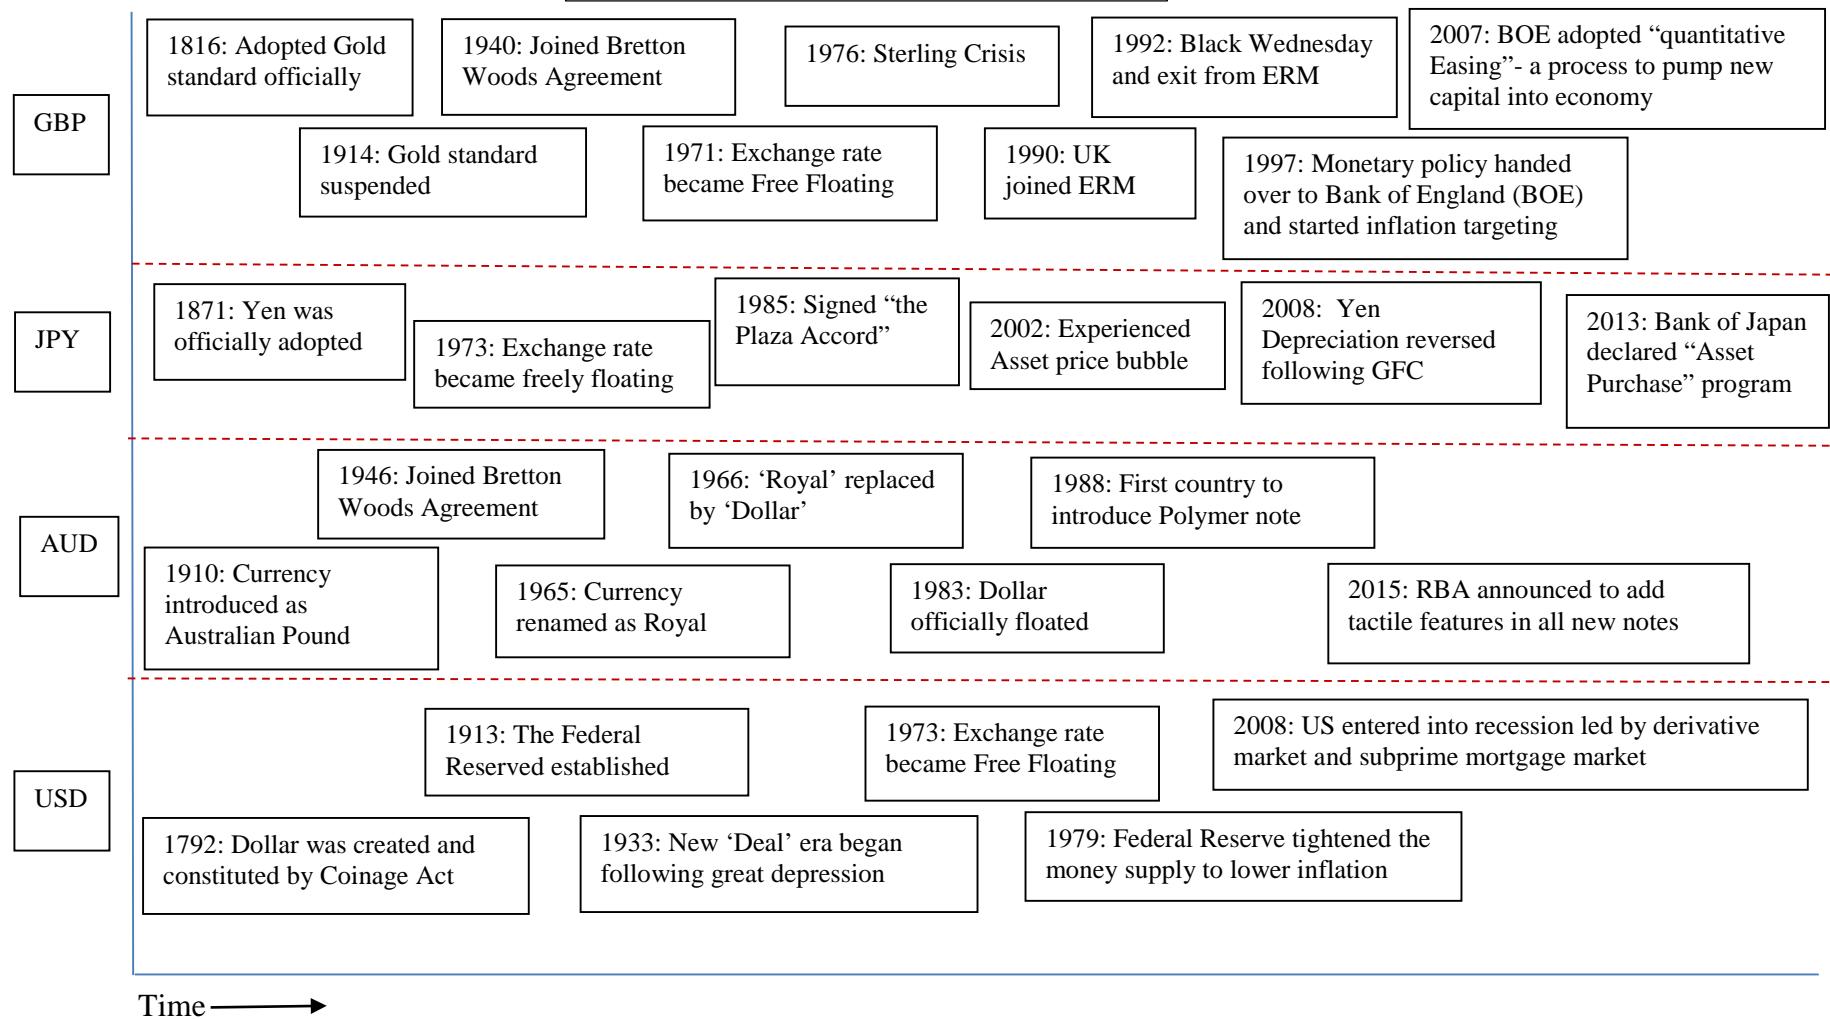

Note: Australian data starts from 1984. All values are statistically significant.

appreciation of the home currency) and relatively larger. This result may have implications for the interactions between exchange rates and world commodity prices (see, Chen and Rogoff, 2003; Clements and Fry, 2008, among others). However, I am reluctant to draw any conclusion regarding being or not being a commodity currency from this, as it requires further analysis on data that is yet to be collected.

## 2.6. Conclusions

Based on the first and second-order moments of real exchange rates, real interest rates and commodity prices, this chapter indicates that exchange rates may not be as volatile as they are generally viewed. There is a tendency for changes in real exchange rates to wash away in the long run. Curiously, real exchange rates have tended to be either uncorrelated or negatively correlated with real interest differentials; however, correlations of both the Australian and the Canadian dollars with world commodity prices tend to provide anecdotal support to a close relationship between exchange rates and of world commodity currency prices. These results have useful implications for further research in exchange rate dynamics, as well as for policymakers and businesses routinely grappled with exchange rate puzzles. Finally, I would like to finish the chapter by providing a diagram containing major historical events of selected currencies.

## Appendix to Chapter 2

This appendix contains real exchange rates and commodity prices in logarithm form and real interest rates that have been used in this chapter. All data are quarterly and for the period 1960Q1-2014Q1. The numerarie currency is the U.S. dollar for all the exchange rates. Table A2.1 contains the real exchange rate data for Australian dollar (AU), Canadian dollar (CN), Japanese yen (JP), the United Kingdom pound sterling (UK), French franc (FR), Deutsch mark (DM), Italian lira (IT) and euro (EU). The commodity price data (CMD) are given in the last column. Table A2.2 contains the corresponding real interest rates data with an ‘I’ added to denote interest rates for the respective countries. Soft copies of all data are contained in excel files and available on request.

## **Chapter 3**

### **Nonlinearity in Exchange Rates**

---

#### **3.1 Introduction**

Exchange rate behavior is still as mysterious as it has historically been in the past. It is now widely accepted that the exchange rates follow a random walk, whereby successive changes in the rates are serially uncorrelated. Unfortunately, empirical testing of the random walk model of exchange rate is controversial because it is possible for exchange rate changes to be linearly uncorrelated, but nonlinearly dependent. This possibility has led to extensive research in the area of nonlinearity in exchange rate. Many of these studies utilize the Multiple Regime Smooth Transition Autoregressive model to evaluate the non-linear relationship between the exchange rate and its fundamentals. Other studies have applied Markov-switching model to the foreign exchange markets and found evidence of frequent shifts of regimes in the relation between the exchange rate and its fundamentals (see, for a review, Taylor and Manzur, 2013). Existing literature tends to provide support to some nonlinear structures that appear consistent with the presence of conditional heteroskedasticity. However, adequate representation of the nonlinear dependence in exchange rate returns continues to remain a puzzle (see, Ballie and Bollerslev, 1989, 2002; Lundbergh et al., 2003; Sollis, 2008). There is widespread controversy surrounding the appropriateness of the model specification, the choice of numeraire currency, the issues of structural change and outliers and so on (see, such as, Giordani et al., 2007).

This chapter contains a systematic analysis of the time series properties of a mixed bundle of currencies since major currencies returned to the floating system in the early 1970s. Our sample includes four major currencies, namely, Canadian dollar, Japanese yen, Swiss franc and the U.S. dollar exchange rate series, all denominated in British pound-sterling, and eight other mixed relatively less-liquid currencies, namely, Chilean peso, Indonesian rupee, Malaysian ringgit, Pilipino peso, Singapore dollar, South African rand, South Korean won and Thai baht. As discussed later (in Section 3.3), the purpose of including these relatively less liquid currencies is to compare and check if nonlinearity is more of a phenomenon for the currencies of less-developed countries. Tests are employed on this sample based on the residuals of

the basic purchasing power parity (PPP) and simple autoregressive moving average (ARMA) equations to empirically determine the presence of nonlinearity, structural change and outliers. The purpose here is to provide further evidence on the properties of the series, rather than designing a statistically adequate empirical model of exchange rate returns. Note that using PPP as a base model puts the focus on real exchange rates, while ARMA describes the behavior of nominal exchange rates. Overall, the results are insightful and provide further evidence to nonlinear dependence in exchange rates.

The significance and innovations of this chapter are attractive. First, it provides updated evidence on the time series properties of representative exchange rates over the current floating rate system spanning last four decades. This is a useful work since further evidence will have important implications for previous work, as well as new work in future research. Second, for nonlinearity test purposes, a more general approach is introduced to specify the PPP equation in which the existence of cointegrating vectors between exchange rates and prices is first verified and confirmed before the check for nonlinearity in an error correction framework. Third, the British pound-sterling, rather than the U.S. dollar, serves as the base currency in this study. Previous literature has shown that the results can be sensitive to the choice of the numeraire currency (see Papell and Theodoridis, 2001). Finally, unlike most empirical research, I have provided tests for structural change and outliers, together with the direct test for the presence of nonlinearity. A clear-cut understanding of the time series properties of exchange rates is pivotal to resolving several outstanding puzzles, including the tests for market efficiency, predictability, forecasting model selection, and more fundamentally, the deviations from PPP.

The chapter is organized as follows. Section 3.2 provides a selective review of the existing literature, followed by a brief reference to analytical considerations in Section 3.3. The description of data and preliminary analysis are contained in Sections 3.4 and 3.5, respectively, while Section 3.6 contains the empirical results. The last section concludes the chapter. This chapter is based on Wali et al. (2014).

### **3.2 A Reference to Literature**

Existing literature points to at least three major sources of nonlinearity in exchange rates. The first and most prominent of these sources is the role of transaction costs and other frictions like tariffs and nontariff barriers to trade. This source of nonlinearity in exchange rates has attracted considerable attention in the literature (see Heckscher, 1916; Benninga and Protopapadakis, 1988; Dixit, 1989; Williams and Wright, 1991; Dumas, 1992; Coleman, 1995; Sercu et al., 1995; Rogoff, 1996, Ohanian and Stockman, 1997; O'Connell, 1997; O'Connell and Wei, 2002). It is argued that due to the presence of transaction cost, arbitrage profit from mispricing of currencies would no longer exist unless the mispricing reaches a certain level, thus showing up as a discontinuity in the behaviour of deviations from the equilibrium exchange rate. A second potential source of nonlinearity, as suggested by Kilian and Taylor (2003), arises from the interaction of heterogeneous agents in the foreign exchange market at the microstructural level giving rise to different beliefs of different market participants regarding the equilibrium exchange rate. A third potential source of nonlinearity, suggested by Sarno and Taylor (2001b) and Taylor (2002, 2003) arises from the types of official interventions in the foreign exchange market. In an effort to contain inflation and manipulate trade flows, some governments or central banks intervene in the foreign exchange market directly or indirectly, causing nonlinearity in the adjustment of the nominal and real exchange rates. It is argued that these interventions may solve a coordination problem in the foreign exchange market. When the exchange rate is grossly misaligned because fundamental traders have lost liquidity (or confidence), they need a coordinating signal in order to enter the market at the same time and correct the misalignment. This coordinating signal is provided by official intervention and is more likely to be successful, the greater the degree of misalignment. These issues relating to nonlinearity are under intense scrutiny by the recently developed literature known as 'new open economy macroeconomics' (NOEM), pioneered by Obstfeld and Rogoff (1995).

The empirical literature has extensively employed the test proposed by Brock, Dechert, Scheinkman (1987), referred to as BDS test, to uncover nonlinear dependence in exchange rates. This procedure tests the null hypothesis that the

residuals are independently and identically distributed (*iid*) against an unspecified alternative. The test has power against both deterministic chaos and nonlinear stochastic systems. The ability of this test to deal with stochastic time series makes its application in applied economics quite appealing. The test is developed on the concept of correlation integral, briefly described as follows.

Let  $\{x_t\}$  be a scalar time series generated randomly according to a density function  $f$ . Arrange  $m$ -dimensional vectors, called  $m$ -histories,  $x_t^m = (x_t, x_{t+1}, \dots, x_{t+m-1})$ . The correlation integral at embedding dimension  $m$  is computed as

$$C_{m,T}(\varepsilon) = 2 \sum_{t=1}^{T-m} \sum_{s=t+1}^{T_m} I_\varepsilon(x_t^m, x_s^m) / (T_m(T_m - 1)) \quad (3.1)$$

where  $T_m = T - m + 1$ , and  $I_\varepsilon(x_t^m, x_s^m)$  is an indicator function of the event  $\|x_t^m - x_s^m\| = \max_{i=0,1,\dots,m-1} |x_{t+i} - x_{s+i}| < \varepsilon$ . Thus, the correlation integral measures the fraction of pairs that lie within the tolerance distance  $\varepsilon$  for the particular embedding dimension  $m$ . The BDS statistic, for the time series of length  $T$  is then defined as

$$BDS_{m,T}(\varepsilon) = T^{1/2} [C_{m,T}(\varepsilon) - C_{1,T}(\varepsilon)^m] / \sigma_{m,T}(\varepsilon), \quad (3.2)$$

where  $T$  is the sample size,  $\varepsilon$  is the arbitrarily chosen proximity parameter, and  $\sigma_{m,T}(\varepsilon)$  is the standard sample deviation of the statistic's numerator that varies with dimension  $m$ . The idea is for BDS test to use pairs of  $m$ -histories that too often cluster together within a specific distance  $\varepsilon$ , and thus reveal hidden patterns that should not occur in truly randomly distributed data. Note that the values of two parameters,  $m$  and  $\varepsilon$  are typically determined *ex ante*.<sup>4</sup> Under certain conditions, the BDS test statistic is asymptotically normal (see Brock et al., 1987). Simulation studies have reported that the test has power against a large class of alternatives, including auto-

---

<sup>4</sup> Kočenda (2001) and Kočenda and Briatka (2005) extends the BDS test by specifying the intervals of the proximity parameter  $\varepsilon$ , but the question regarding the choice of embedding dimension,  $m$ , remains unresolved.

regressive conditional heteroskedastic (ARCH) models (see Bollerslev, Engle and Nelson, 1994). However, the interpretation of this test is not all that clear-cut, and consequently, a rejection of the null hypothesis do not suggest the type of alternative models one should consider (see Granger and Terasvirta, 1993). Studies using BDS test include Scheinkman et al (1989), Hsieh (1989, 1991), DeGrauwe et al. (1993), Brooks (1996), Mahajan and Wagner (1999), Clarida et al. (2003), Rahman and Saadi (2008), Emekter et al. (2009), among others. Most of these studies using different base currencies report evidence in support of nonlinear dependencies in exchange rates. This chapter contributes to the literature by confirming that similar results can be obtained when using GBP as based currency.

The literature includes several other statistical tests for detecting nonlinear dependence in exchange rates. McLeod and Li (1983) show that the autocorrelation coefficients and Box-Pierce Q-statistics of the squared residuals of an ARMA model can be used to test for nonlinear dependence. Tsay (1986) proposes a generalised version of Keenan's (1985) test by adopting a three-stage estimation routine. Both Tsay and Keenan Tests are directly designed to test for departures of linearity in mean. Another approach is to use the bi-spectrum, which is the double Fourier transform of the third order cumulant function, and this forms the basis of the test for Gaussianity and linearity as suggested by Hinich (1982), following Subba Rao and Gabr (1980). For a fuller exposition and comparative analysis of these and similar other tests, see Lee et al. (1993) and Brooks (1996). An important conclusion of these comparative studies is that no single test is uniformly superior to the others. More recently, significant efforts have also been directed to nonparametric entropy-based tests of independence in exchange rates. These tests rely on kernel-based estimation techniques in which kernels and bandwidths are typically selected by the researcher. Besides, the finite sample level of these tests differs from the asymptotic one, and the constructs lose certain amount of detailed information (see, Granger et al., 2004; Racine and Maasoumi, 2007; Martilla-Garcia and Marin (2008); Fernandes and Neri, 2009; Yoon, 2010, among others). In traditional applications (eg Mann-Whitney and Wilcoxon) if the test assumptions hold, parametric tests have greater power than non-parametric tests. The value of non-parametric tests is when the assumptions do not hold.

The potential nonlinearity in exchange rates adds a new dimension to testing the empirical validity of PPP. Note that PPP is arguably the oldest and most durable workhorse in exchange rate economics (see Manzur, 2008). In its simplest form, PPP implies that for there to be no unexploited profits, arbitrage ensures equalisation of national price levels when expressed in a common currency. Thus, we have:

$$S_t = \beta_0 + \beta_1 P_t - \beta_2 P_t^* + \varepsilon_t \quad (3.3)$$

where  $S_t$  is the logarithm of the domestic currency cost of one unit of a foreign currency at time  $t$ ,  $P_t$  and  $P_t^*$  are the logarithms of the domestic and foreign price levels, respectively, and  $\varepsilon_t$  is the disturbance term capturing deviations from PPP. Note that the term  $\varepsilon_t$  in equation (3.3) identically coincides with a measure of the real exchange rate under PPP so that, we have

$$d_t = \beta_0 + \varepsilon_t = S_t - P_t + P_t^*. \quad (3.4)$$

Earlier tests of PPP focused on  $d_t$  using conventional linear unit root tests, and a vast majority of them rejected PPP (see, for a survey, Taylor, 2006). However, the well-known PPP puzzle raised by Rogoff (1996) has seen a new wave of literature unraveling the low power of the linear autoregressive models and accounting for nonlinearity in exchange rates.<sup>5</sup> Prominent nonlinear approaches include the threshold autoregressive (TAR) model of Tong (1978) and smooth transition model can be defined as follows:

$$d_t = \beta_0 + \sum_{i=1}^p \phi_i d_{t-i} + \left( \sum_{i=1}^q \theta_i d_{t-i} \right) F(x_t; c) + u_t \quad (3.5)$$

---

<sup>5</sup> Rogoff (1996) highlights the puzzle that existing models seem inadequate to explain the ‘excessive’ persistence in the real exchange rate and its huge short-term volatility. More specifically, if nominal price distortions are really responsible for short-term PPP deviations, ‘one would expect substantial convergence to PPP over one to two years, as wages and prices adjust to shock’ (p.654). The consensus estimate of convergence to PPP is between 3 and 5 years.

where  $x_t$  is the transition variable, it could be the lagged value of  $d_t$  or any other exogenous variables,  $c$  is the threshold value and  $F(x_t; c)$  is an indicator function such that

$$F(x_t; c) = \begin{cases} 0, & x_t < c \\ 1, & x_t \geq c. \end{cases}$$

Equation (3.5) is usually estimated via a grid search on the thresholds, and the restrictions are tested accordingly. In the case of STAR model, the indicator function  $F(x_t, c)$  is replaced by a transition function, which can be any continuous and twice differentiable function that ranges from 0 to 1. In the STAR literature, the logistic function (LSTAR) and the exponential function (ESTAR) are among the popular specifications of  $F(x_t, c)$  (see Terasvirta, 1994). For a survey on the developments of STAR modeling, see van Dijk et al. (2002). Studies using an ESTAR framework include Michael et al. (1997), Baum et al. (2001), Taylor et al. (2001), O'Connell and Wei (2002), Kilian and Taylor (2003), among others, and provide evidence in support of nonlinear mean reversion of real exchange rates. Their findings generally support the existence of two regimes in exchange rates. While the speed of adjustment and the threshold values varied between exchange rates and the period used for estimation. Overall, they provide some evidence supporting that (i) exchange rates follow different regimes and (ii) the transition between regimes is smooth rather than abrupt.

Overall, the evidence, as above, is at best mixed. The performance of the class of nonlinear models in out-of-sample forecasting has not been encouraging (see, Clarida et al. 2003; Rapach and Wohar, 2006, among others). Empirical studies have typically considered nonlinearity, structural change and outliers in isolation, rather than all of these properties simultaneously. It is argued that the apparent nonlinearity in exchange rates could simply be due to structural breaks or outliers in the series (see, for example, Villavicencio, 2008). Thus, the need for further work on these issues cannot be underestimated.

### 3.3 Econometric Issues

A problem with specification such as equation (3.5) is that it focuses on the deviation from PPP, namely,  $d_t$ . Given the strong empirical evidence suggesting that  $S_t$ ,  $P_t$  and  $P_t^*$  are  $I(1)$ , the specification relies heavily on the assumption that  $(1, -1, 1)'$  is a cointegrating vector, that is,  $S_t - P_t + P_t^*$  is stationary (or  $I(0)$ ). However, if this is not true, then  $d_t$  will be non-stationary and standard approaches in estimating nonlinear models, such as those specified in equation (3.5) will not be appropriate.

I propose to resolve this issue by tackling the problem in a slightly more general form, which allows proper testing on (i) the existence of cointegrating vectors between exchange rates and prices, and (ii) the existence of non-linearity in the vector error correction model (VECM). Under the assumption that there is a cointegrating vector between the three variables, then by the Granger's representation theorem (Engle and Granger, 1987), there must exists a vector error correction representation for exchange rate, that is:

$$\Delta S_t = \alpha(S_{t-1} - \beta_1 P_{t-1} - \beta_2 P_{t-1}^*) + \sum_{i=1}^K (\delta_{si} \Delta S_{t-i} + \delta_{pi} \Delta P_{t-i} + \delta_{p_i^*} \Delta P_{t-i}^*) + \varepsilon_t \quad (3.6)$$

where  $\Delta$  is the change operator, and  $\varepsilon_t$  is an error term which does not have to be iid.

Equation (3.6) is general enough to cover all previous cases as special cases. For example, Equation (3.6) reduces to Equation (3.5) by setting  $\beta_1 = 1$  and  $\beta_2 = -1$  along with the restrictions that  $\delta_{si} = \delta_{pi} = \delta_{p_i^*} = 0$  for all  $i$ . Obviously, if cointegrating vector does not exist, it is equivalent to  $\alpha = 0$ . In such a case, equation (3.6) with an appropriate serial correlation structure is ensured by the Wold's decomposition on the stationary variable,  $\Delta S_t$ , and consequently, no long run relationships exist between the three variables. Furthermore, equation (3.6) specifies that the exchange rate change is a linear function to the past values of all three variables as well as the error correction term. Therefore, any potential nonlinearity will be embedded in the estimated residuals,  $\hat{\varepsilon}_t$ . That is, detecting potential nonlinearity in the exchange rate

can be achieved by testing the existence of nonlinearity in the estimated residuals in (3.6). Thus, equation (3.6) provides a more complete platform to examine nonlinearity in exchange rates. Equation (3.6) also nests an ARMA representation of delta S. Under the assumption  $\alpha = 0$  and epsilon follows an AR(q) process then delta S follows an ARMA-X process.

Under the null of  $\varepsilon_t$  being a sequence of iid random variable, the Johansen's (1988) trace and max tests can be used to determine the number of cointegrating vectors among  $(S_t, P_t, P_t^*)$ . Once the number of cointegrating vectors has been determined then the coefficients in equation (3.6) can be estimated by reduced-rank regression algorithm as proposed in Johansen (1988). The estimated residuals,  $\hat{\varepsilon}_t$  can then be obtained in a natural way and can be used for purposes of analyzing the potential nonlinear structure in  $\Delta S_t$ . These procedures are adopted in the empirical analysis section of this chapter.

### 3.4 Data

Exchange rate data series are all monthly and denominated in British pound-sterling (domestic currency cost of GBP 1). Our sample consists of two sets of currencies. In the first set, we have four major exchange rates of the Canadian dollar (CAD), Japanese yen (Y), Swiss franc (CHF), US dollar (USD), all denominated in British pound sterling (GBP). Euro is not included in this study as it has a relatively shorter period of existence. The data for these four currencies start from 1973(1) to 2013(4). For comparison purposes, included is a mixed bundle of eight globally-representative currencies of economies with a sufficiently long history of exchange rates, namely, Chile (CLP), Indonesia (IDR), Malaysia (MYR), Philippines (PHP), Singapore (SGD), South Africa (ZAR), South Korea (KRW) and Thailand (THB). The idea is to consider whether there is any difference in the extent of nonlinearity between the most-traded currencies in large volumes, such as the major ones listed above, and those which are less frequently traded in considerably smaller volumes, such as those in our mixed bundle. Possibility of this difference arises from the notion that the most-traded currencies are subject to closer market scrutiny (by analysts, traders and regulators), and hence any autoregressive dependencies in their returns are likely to be arbitrated away instantaneously (see, Brooks, 1996). The data for Chile are for the

period from 1976(1) to 2013(4), and for the remaining countries in this group, from 1979(1) to 2013(4). Consumer price index (CPI) is used as the measure of inflation. All data are from the International Financial Statistics (IFS) through DataStream and appended at the end of this chapter.

### 3.5 Basic Statistics and Preliminary Analysis

Descriptive statistics of the exchange rate series are provided in Table 3.1. All the data are in log change from. The statistics are presented separately for the two sets of currencies. As can be seen, the kurtosis measures for all exchange rates are larger than the standard normal distribution measure 3.0. The Jarque-Bera test statistics indicate departure from normality in the exchange rate returns of all the countries.

**Table 3.1: Summary statistics of the exchange rate series (log-change):  
1973(M1)-2013(M4)**

Highly Liquid Currencies						
Exchange rate	Mean	Median	Std. Dev.	Skewness	Kurtosis	Jarque-Bera
CAD	-0.0009	-0.0019	0.0303	-0.0247	4.39957	38.65 (0.00)

Note: Figures in parenthesis are the p-values. The variables in two digits are the respective exchange rates of the respective countries against British pound sterling and the three-digit variables are the respective price levels.

Next, standard tests have been employed to check for the stationarity of the series of both exchange rates and price levels. Table 3.2 contains the unit root test results of both Augmented Dickey-Fuller (ADF) and Phillips-Perron (PP) tests (with and without trend). The results in this table indicate that both ADF and PP tests cannot reject the null of a unit root in levels, but the series tend to be stationary in their first differences for all countries except for UK and Chile. For these two countries the series in question tend to be stationary in both levels and first differences. This presents a problem for our subsequent cointegration analysis, as the test for a cointegrating vector requires the series to be I(1) in levels. This problem is addressed by treating the UK CPI as an exogenous variable, and dropping Chile from our subsequent analysis.

### 3.6 Empirical Results

As indicated in Section 3.3, Johansen's (1988) trace and max tests have been conducted first to determine the number of cointegrating vectors among  $(S_t, P_t, P_t^*)$ <sup>6</sup>. The UK is the numeraire country for both exchange rate and relative inflation and treated as an exogenous variable. As the data are monthly, lags specified are 1 to 12. The critical values for the test have been computed using

**Table 3.3: Cointegration results: exchange rates and prices (in logarithm)**

	Data Trend	None		Linear		Quadratic
		Test Type	No Intercept	Intercept	Intercept	
		No Trend	No Trend	No Trend	Trend	
United States	Trace	2	1	1	1	2
	Max Eig	2	1	1	1	2

MacKinnon-Haug-Michelis (1999) p-values. The results are presented in Table 3.3. The focus here is on the column with linear trend and tests with both intercept and

---

<sup>6</sup> Eviews 8 is used for this and other tests in this section.

trend, which is considered appropriate when the data tend to be trend stationary<sup>7</sup>. As can be seen, no integrating relationship is present between exchange rates and price levels for Indonesia, Malaysia, Thailand and South Korea, while there is at least one cointegrating vector for the remainder of the countries. Consequently, we discuss the empirical results of these four countries first, followed by those for the rest of our sample.

### 3.6.1 Non-cointegrating currencies

For Indonesia, Malaysia, Thailand and South Korea, we estimate equation (3.3) using OLS in the following form:

$$\Delta S_t = \alpha_0 + \beta (\Delta P_t - \Delta P_t^*) + \varepsilon_t \quad (3.7)$$

where  $\varepsilon_t \sim iid(0, \sigma_\eta^2)$  are assumed to be iid random variables with zero means and finite variances. Note that estimating equation (3.7) is tantamount to testing PPP. For PPP to hold,  $\beta$  in the above equation needs to be unity. As can be seen from Table 3.4,  $\beta$  is not statistically significant for any of the pairs of currencies.

**Table 3.4: PPP estimation results: non-cointegrating countries**

$y_t = \alpha + \beta (\pi_t - \pi_t^*) + \eta_t$					
$y_t$	$\alpha$	$\beta$	Std. Error	R <sup>2</sup>	DW
IDR/GBP	0.0040	0.4811	0.0671	0.0090	1.8124
KRW/GBP	0.0015	-0.1025	0.0429	0.0003	1.9508
MYR/GBP	0.0001	-0.1213	0.0365	0.0005	1.9417
THB/GBP	0.0004	0.0204	0.0358	-0.0011	1.8223

Note: None of the above values are significant even at 10%

Next, the BDS test is conducted on the residuals of the estimated series for these four countries. Note that the currencies of these four countries are relatively less liquid. The BDS test results are given in Table 3.5. Note that, for the BDS tests

---

<sup>7</sup> In practice the test without any intercept and trend in no trend assumption is hardly used because of its extreme assumptions. For the same reason test with intercept and trend for quadratic trend is rarely used. As a rough guide, it is advisable to use test with intercept and no trend if none of the series appear to have a trend. For liner trending series, test with intercept and no trend is advisable to use.

statistics of the residuals reported, embedding dimensions (m) are 6. The distance measure  $\varepsilon$  approximately equals to 0.5. This is used by default in Eviews. For comparison purposes, also reported are the results of the Breusch-Godfrey Lagrange multiplier (LM) test for serial correlation. Under the alternative of the LM test, the residuals are linearly related to its past values and therefore it is a test of linear dependence in the residuals against the null hypothesis of independence. As can be seen, the reported p-values for the LM test indicate that the null hypothesis of no serial correlation cannot be rejected for all currencies except IDR/GBP. In the case of the BDS test, the null of iid is rejected for all four currencies.

**Table 3.5: LM and BDS test on PPP residuals: non-cointegrating countries**

Exchange rate	LM	BDS
IDR	0.0142	0.0000
KRW	0.7554	0.0000
MYR	0.1570	0.0002
THB	0.1449	0.0000

Note: The numbers reported in the table are the associated p-values for each test, with dimension set equals to 2. Other dimensions were also tried with similar results.

We double-check these results with those using an ARMA of the following form:

$$\Delta S_t = \alpha_0 + \sum_{i=1}^p \theta_i S_{t-1} + \sum_{j=1}^q \phi_j \varepsilon_{t-1} + \varepsilon_t \quad (3.8)$$

where  $\varepsilon_t \sim iid(0, \sigma_\varepsilon^2)$ . The optimal lags are based on the lowest Schwarz Information Criterion (SIC), and the results are reported in Table 3.6. As reported, none of the

**Table 3.6: ARMA estimation results: non-cointegrating countries**

$y_t$	Lag Length	$y_t = \alpha_0 + \sum_{i=1}^p \theta_i y_{t-1} + \sum_{j=1}^q \phi_j \varepsilon_{t-1} + \varepsilon_t$				DW
		$\alpha_0$	$\theta_i$	$\phi_j$	R <sup>2</sup>	
IDR/GBP	0,1	0.0060			0.0166	2.0184
KRW/GBP	2,0	0.0012	0.0306		0.0011	2.0003
			0.0253			
MYR/GBP	0,1	0.0001		0.0232	0.0006	1.9950
THB/GBP	0,1	0.0001		0.0963	0.0085	2.0004

Note: None of the above values are significant even at 10%

ARMA coefficients are significant, not even at 10% level. As with the PPP model, the LM and BDS tests are conducted on the residuals of the estimated series for these four countries. As can be seen, both LM and BDS test results on ARMA residuals in Table 3.7 are qualitatively similar to those in Table 3.5. For the BDS tests statistics of the residuals reported, embedding dimensions ( $m$ ) and distance measure  $\epsilon$  approximately equals to 6 and 0.5 respectively. Please note, in our case variation of ( $m$ ) or  $\epsilon$  will not have impact on the result we are reporting or looking at. The LM test cannot reject the null of no serial correlation for all exchange rates except KRW/GBP. In the case of the BDS test, null of iid is rejected in all four cases. Overall, the results of Table 3.4 and Table 3.5 provide evidence rejecting iid and serial independence for these four less-liquid currencies. This result is consistent with the notion alluded to in Section 3.4, but at variance with the earlier literature (see, such as, Brooks, 1996). In what follows, we provide further investigations of these results.

**Table 3.7: LM and BDS test on ARMA residuals: non-cointegrating countries**

Exchange rate	LM	BDS
IDR	0.2873	0.0000
KRW	0.0023	0.0000
MYR	0.1077	0.0005
THB	0.0824	0.0000

See notes to Table 3.5

We employ the Andrews (1993) test to detect the existence of structural instability in the PPP model over the sample period. Structural instability in the series can adversely affect various diagnostic tests, including the BDS test (see, such as, Sibbertsen, 2004 and Banerjee and Urga, 2005). The Andrews test has two attractions: (i) the potential break point, if exists, is estimated, rather than assumed exogenous, and (ii) the asymptotic distribution is nonstandard. Standard tests, such as the classical Chow test does not accommodate these problems.

Equation (3.7) is used for the Andrews test and the results are given in Table 3.8. For purposes of comparison, we have also included the results from the three variants of the Chow test by assuming the break date to be January 1999 (introduction of euro). The idea of the breakpoint Chow test is to fit the equation separately for each subsample and to see whether there are significant differences in the estimated

equations. A significant difference indicates a structural change in the relationship. The software ‘Eviews’ reports three test statistics for the Chow breakpoint test. The F-statistic, the log likelihood ratio statistic and the Wald statistic. To know the details process please see Chow, Gregory C. (1960). Also note that Andrew test applies the Chow test recursively and select the potential break date based on the test statistics with the highest probability to reject the null hypothesis of no break. As can be seen, the results are mixed; there is no evidence of structural instability for KRW and MYR, while IDR and THB seem to have experienced structural breaks in their series. Note that the Chow test has failed to identify the presence of structural instability for all four countries. This indicates the impacts of unknown break date and non-normal errors. While it is well known that the Chow test required normality, the fact that both Andrews and Chow tests provided similar results suggest that non-normality is not the underlying cause on the non-rejection of a structural break. Please note, Andrews test does not require the identification of the break date in prior. While the Chow test does require such information, the results have been robust with different break dates. Given both Andrews and Chow tests provided qualitatively similar results, it is clear that non-normality is not the cause since the Andrews test does not require any distributional assumption.

**Table 3.8: Breakpoint test results: non-cointegrating countries**

Exchange rate	Inflation differential	Andrews	Chow (F-sts)	Chow's (L-L)	Chow (Wald sts)
IDR	IDI-UKI	0.0001	0.1541	0.1513	0.1528
KRW	KWI-UKI	0.5750	0.4311	0.4276	0.4304
MYR	MYI-UKI	0.7377	0.1689	0.1660	0.1676
THB	THI-UKI	0.0043	0.3473	0.3437	0.3463

Note: Andrews Maximum LR / minimum Wald F statistics is reported. F-sts, L-L and wald sts are the F-statistic, Log-likelihood ratio statistic and Wald statistic respectively. Chow tests have been conducted for the periods before and after January 1999.

The presence of influential observations, such as outliers and extreme observations may also bias the BDS test to reject the null. Consequently, it is important to examine the importance of these aberrant observations on the BDS test statistics. To identify the contribution of outliers, we employ a crude, but simple and sensible technique, whereby we re-estimate the BDS test statistics after reducing the

size of aberrant observations by a sample-trimming algorithm. The trimming algorithm can be summarized as follows:

Step 1: Let  $s$  be the estimated standard deviation of the residuals.

Step 2: Set  $n=1$ .

Step 3: Let  $|a(n)|$  be the  $n^{\text{th}}$  observation and let  $\text{abs}(x)$  denotes the absolute value of  $x$ . If  $|a(n)| > 3s$  then set  $a(n) = 3s$ ; else if  $2.5 < |a(n)| \leq 3s$  then set  $|a(n)| = 2.5s$ ; else if  $2 < |a(n)| \leq 2.5s$  then set  $|a(n)| = 2s$ ; else keep  $|a(n)|$ .

Step 4: Set  $n=n+1$  and repeat Step 3 until  $n=T$  where  $T$  is the total number of observations. Note that the above sample trimming procedure does not involve omission or removal of outliers but rather reduce their impacts on estimation and testing.

Table 3.9 contains the LM and BDS test results before and after adjusting for outliers using the above algorithm. P-values have been reported here. As can be seen, the test results before and after outlier adjustments are very similar. This seems to suggest that our test results are unaffected by outliers and extreme observations. Thus, these results, along with the results from the structural stability tests, provide evidence in support of the presence of nonlinearity in exchange rates for this sample.

**Table 3.9: LM and BDS test statistic before and after adjusting outliers: non-cointegrating countries**

Exchange rates	Before Adjusting Outliers		After Adjusting Outliers

### 3.6.2 Currencies with At Least One Cointegrating Vector

Based on the results as reported in Table 3.3, we now turn to the countries in our sample that have at least one integrating vector among the variables  $(S_t, P_t, P_t^*)$ . These countries are the USA, Canada, Japan, Switzerland, Singapore, Philippines, South Africa and Chile. As before, equation (3.7) is estimated for these countries, followed by employing BDS and LM tests on the residuals of the estimated series. The BDS and LM test results are given in last two columns of Table 3.10. Note that the regressing results of equation (3.7) for these countries are not reported here for brevity. As can be seen, the reported p-values for the LM test indicate that the null hypothesis of no serial correlation cannot be rejected for all currencies except JPY/GBP. In the case of the BDS test, the null of iid is rejected for all currencies except for the Canadian dollar, yen and Singapore dollar. First two columns of Table 3.10 is the ARMA counterpart of last two columns. As can be seen, the results on ARMA residuals are qualitatively similar to those of PPP residuals. The LM test cannot reject the null of no serial correlation for all exchange rates. In the case of the BDS test, the results indicate that the null of iid is rejected for all other currencies except the Canadian dollar, Japanese yen and Singapore dollar, as in Table 3.8. The results of these two tables indicate that the data tend to support nonlinear dependence in exchange rates, but the evidence for the major currencies is not all that clear-cut.

**Table 3.10: LM and BDS on ARMA and PPP residuals: cointegrating countries**

Exchange rate	ARMA		PPP	
	LM	BDS	LM	BDS
CAD	0.9365	0.1940	0.9990	0.1576
JPY	0.1254	0.4424	0.0705	0.6001
CHF	0.9905	0.0001	0.4795	0.0000
USD	0.4969	0.0338	0.1609	0.0051
PHP	0.8749	0.0065	0.7921	0.0076
ZAR	0.9115	0.0000	0.9459	0.0000
SGD	0.9168	0.1383	0.5970	0.1211

See notes to Table 3.5

Next, as discussed in Section 3.3, we test these currencies for cointegration via the Johansen (1988) procedure. Specifically, the coefficients in equation (3.6) are estimated by reduced-rank regression algorithm as proposed in Johansen (1988). The

estimated residuals are then subjected to the BDS test to identify the potential nonlinear structure in exchange rates. The alpha value is set following the convention of the literature and set at 5%. The VECM coefficient and BDS test results are presented below in Table 3.11. In this table the BDS test results of ARMA residuals from Table 3.10 are reproduced for comparison purpose. As can be seen, test results are not different at all qualitatively. This seems to provide confirmation to the results reported in our previous two tables.

**Table 3.11: VECM and BDS results: cointegrating countries**

Exchange rate	$\beta_0$	$\frac{\beta_1}{\alpha_1}$	BDS Before	BDS After
CAD	-6.6514	39.2593	0.1940	0.3140
JPY	28.1166	-14.3568	0.4424	0.4265
CHF	-6.2998	3.043478	0.0001	0.0092
USD	-1.3475	1.017195	0.0338	0.0739
PHP	-6.6928	17.46073	0.0065	0.0217
ZAR	-19.1617	38.22785	0.0000	0.0000
SGD	4.6342	0.069854	0.1383	0.6712

Notes: VECM coefficient and p values of BDS test are reported.

Breakpoint test and the effect of outliers for these currencies have been tested. Table 3.12 reports the Andrew's breakpoint test results also been checked with no difference in the results. As can be seen, the results do not indicate the presence of structural instability for all eight countries.

Table 3.13 reports and compares the BDS and LM test results conducted on the ARMA residuals before and after adjusting the outliers. As can be seen, the results are not significantly different from each other, thus confirming that impact of outlier is not an issue in the case of linearity or otherwise for these data.

**Table 3.12: Breakpoint test results: Quandt-Andrews test and Chow's test for cointegrating countries**

Exchange rate	Inflation differential	Quandt-Andrews	Chow's test (F-stat)	Chow's test (Log-Like)	Chow's test (Wald stat)
CAD	CNI-UKI	0.9496	0.5251	0.5223	0.5247
JPY	JPI-UKI	0.1806	0.1066	0.1046	0.1055
CHF	SWI-UKI	0.1461	0.4646	0.4617	0.4641
USD	USI-UKI	0.3709	0.2875	0.2846	0.2866

See notes to table 3.5

### 3.7 Conclusion

This chapter has focused on the time series properties of major currencies since their return to floating rates in the early 1970s. The major currencies included here are the U.S. dollar, Canadian dollar, Japanese yen and Swiss franc exchange rate

series, all denominated in British pound-sterling. We also include in our sample a mixed bundle of eight other relatively less-liquid currencies for comparison purposes. Alternative specifications and test procedures have been employed for this purpose. We provide direct tests for the presence of nonlinearity, structural change and outliers. The results are quite instructive. The BDS test results reject iid for the less-liquid currencies. This result is consistent with the notion that the less-liquid currencies are subject to lesser scrutiny by the market agents and consequently, any autoregressive dependencies in their returns tend not to be arbitrated away instantaneously. However, the results for the major currencies are not all that clear-cut. Unlike most other studies, we find that the Canadian dollar, yen and Singapore dollar returns tend to be iid. In future research, it may be worthwhile to dig further whether this result is attributable to the choice of the numeraire currency.

### Appendix to Chapter 3

Table A3.1 lists Canadian dollar (CN), Chilean peso (CP), Indonesian rupiah (ID), Japanese yen (JP), Malaysian ringgit (MY), Pilipino peso (PH), Singapore dollar (SG), South African rand (SA), South Korean won (KO), Swiss franc (CH), Thai baht (TH), and U.S. dollar (US), all denominated in British pound sterling (UK). These are monthly exchange rates data for the period Jan-1973 to May-2014. Note that the data in this chapter cuts-off in April 2013. Next chapter uses the same sample countries and data, and the additional data listed in Table 3.1 are used in the next chapter. Also the CPI data used in this chapter are appended at the end of Chapter 4. Soft versions of these data are available on request.

## **Chapter 4**

### **Purchasing Power Parity and Panel Data Tests**

---

#### **4.1 Introduction**

Purchasing power parity (PPP) is perhaps the oldest and most controversial theory of exchange rate determination. Absolute PPP states that the exchange rate is given by the ratio of domestic to foreign price levels. The relative version implies that the change in the exchange rate is approximately equal to the inflation differential. Under PPP, prices of goods and services are internationally arbitrated so that they are the same in all locations when expressed in a common currency. Note that PPP is more of an empirical proposition and the real exchange rate is constant under this proposition. Despite its long and chequered history, PPP continues to occupy the centre stage of research in exchange rate economics for two important business implications. First, PPP serves as the benchmark to judge the level of an exchange rate. This implies that PPP enables us to have meaningful discussions about over- or undervaluation of a currency. Second, PPP serves as a simple prediction model for exchange rates.

Empirical research on PPP is arguably the most voluminous in the exchange rate literature (see for surveys, among others, Rogoff, 1996, Taylor, 2003, Manzur, 2003, Manzur, 2008, Taylor and Manzur, 2013). While the content of PPP has historically been tested using several procedures, the focus has recently concentrated on time series econometrics involving unit root and cointegration properties of variables in panel frameworks. The test of PPP for a panel of countries is grounded on the idea that this framework enlarges the size of the sample (which is relevant for focusing on long-run PPP) and hence increases the statistical power of the test. In a panel framework, both unit root and cointegration procedures have gained popularity. The unit root procedure tests for a unit root in real exchange rates, while the cointegration procedure tests for a cointegrating relationship between various measures of domestic and foreign prices as well as nominal exchange rates. While the panel approach has made significant advances in the PPP literature, many questions remain.

This chapter systematically provides a re-examination of the empirical content of PPP for the same sample as in the previous chapter using panel data techniques. Alternative panel unit root tests are employed with the British pound sterling (GBP) as the numeraire currency. Results are then compared with a U.S. dollar-based panel. The purpose is to provide evidence if the results are sensitive to the choice of the numeraire currency (see Papell and Theodoridis, 2001). Panel unit root results are further analysed using alternative panel cointegration tests. The reason for this cointegration test is that, non-rejection of unit roots in real exchange rate do not necessarily imply a rejection of PPP. If nominal exchange rates and relative price levels are integrated of order one (in levels), then it is possible that these two variables may be cointegrated, implying a close relationship in the long run. Overall, the results are not encouraging for PPP. The sample of 12 countries is then divided into 3 subgroups to check if the results are sensitive to country characteristics. Again, the data tend to reject PPP. Note that this chapter uses the same sample countries and data as those in the previous chapter with slightly updated cut-off period.

The study in this chapter makes two contributions. First, it represents empirical applications of recent methodological developments in the PPP literature thereby providing updated evidence using the most recent data. Second the results of this chapter are expected to contribute to the understanding of the role of numeraire or base currency in PPP analysis. The chapter is organized as follows. The next section provides a brief reference to literature, followed by analytical considerations in Section 4.3. The data are discussed in Section 4.4 and empirical results are contained in Section 4.5. The last section concludes the chapter.

## 4.2 Brief Review of Literature

Efficient market version of PPP is empirically tested in the early literature in two ways. The first is to test for the stationarity of the real exchange rates using classical univariate procedures, such as the one proposed by Dicky and Fuller (1979). Studies using this approach include, among others, Mark (1990), Grilli and Kaminsky (1991), Flynn and Boucher (1994), Yazgan (2003) and Narayan (2005, 2006). A second approach, pioneered by Engle and Granger (1987), and subsequently, Johansen and Juselius (1990), is to test for cointegration between nominal exchange rates vis-a-vis some common currency, such as the US dollar, and relative prices. For

PPP studies along this line, see such as, Corbae and Ouliaris (1991), Enders (1988), Taylor (1988), Fisher and Park (1991), Cheung and Lai (1993) and Thacker (1995). In general, empirical studies employing classical unit root and cointegration procedures have rejected PPP.

As classical tests have low statistical power, the authors have developed what is now known as the multivariate panel data test, whereby PPP is tested by pooling the time series data across a panel of members or countries. For panel unit root tests, Im et al. (2003) [hereafter IPS], Levin et al. (2002) [hereafter LLC], Maddala and Wu (1999) [hereafter MW] and Pesaran (2007) are among the leading exponents. Ghoshroy-Saha and Berg (1996), O'Connell (1998), Papell and Theodoridis (1998) Fleissig and Strauss (2000), Ho (2002), Taylor (2002), Huseyin (2005), and Chang et al. (2006), among others, employ this methodology for PPP and provide mixed evidence. A parallel development has been the panel cointegration tests, proposed by Pedroni (1999, 2004) and Westerlund (2007), among others. Studies such as Azali et al. (2001), Nagayasu (2002), Basher and Mohsin (2004), and Jenkins and Snaith (2005) examine PPP using the Pedroni panel methodology with mixed results.

Panel frameworks exploit both time-series and cross-section information and have the advantage that their asymptotic distribution is standard normal (see Baltagi et al. 2007). However, several issues remain unresolved in panel data methods. For example, homogeneity in panels as required by some of these tests such as LLC and IPS, is hard to observe in the real world. Consequently, the authors resort to the assumption of cross-sectional independence, thereby making the results restrictive and difficult to interpret. Several studies have proposed to model cross-sectional dependence using nonlinear IV (instrumental variable) and GLS-demeaning procedures (see such as, Chang, 2002; 2004). Given the restrictive nature of these approaches, authors have introduced dynamic factor models that involve two steps: first, use orthogonalisation type methods to asymptotically eliminate cross section dependence of the series; and second, apply standard unit root tests to the transformed series (see such as, Bai and Ng , 2004; Moon and Perron 2004; Phillips and Sul, 2003). Pesaran (2007) proposes an alternative to the factor based tests, whereby standard panel unit root tests are based on the simple averages of the individual cross-sectionally augmented ADF statistics (CADF). By comparison to panel unit root tests,

the cointegration analysis in panels is still at an early stage of its development. In panel cointegration framework, testing of hypothesis and estimation procedures are further complicated by the presence of cross section cointegration. These and other issues are currently the subject of extensive research (see Breitung and Pesaran, 2008 for a review).

### 4.3 Analytical Framework

This study employs MW and CADF methods for panel unit tests of PPP. MW test has several attractions in that it allows for the flexibility in the size and dimension of the time series and cross sections, and that the alternative hypothesis allows some members to have unit roots while others may not (see Baltagi et al., 2007). CADF is a simpler procedure to get rid of cross-sectional dependence. Similarly, two separate cointegration tests are employed, namely, the one proposed by Pedroni (2004) and the other one proposed by Westerlund (2007). In what follows, these tests are briefly discussed.

#### 4.3.1 MW and CIPS Tests

MW test is implemented using the Augmented Dicky-Fuller (ADF) which follows Fisher (1932) unit root test. This test can also be implemented using the Phillips-Perron's (PP) unit root test (Phillips and Perron, 1988). Consider the following ADF regressions for each cross section:

$$\Delta y_{it} = \rho_i y_{it-1} + \sum_{t=1}^{\rho_i} \beta_{it} \Delta y_{it-j} + X_{it} \delta + \varepsilon_{it} \quad (4.1)$$

where  $i = 1, 2, \dots, N$  represents cross-section units that are observed over periods  $t = 1, 2, \dots, T$ .  $X_{it}$  represents the exogenous variables including any fixed or individual trend,  $\rho_i$  is the autoregressive coefficient and  $\varepsilon_{it}$  is idiosyncratic disturbance. If  $|\rho_i| < 1$ ,  $y_i$  is said to be weakly stationary and if  $|\rho_i| = 1$ , then  $y_i$  is said to contain a unit root. The null hypothesis is  $H_0 : \rho_i = 0$  for all  $i$  and the alternative hypothesis is that not all of the individual series have a unit root:

$$H_0 : \rho_i = 0$$

$$H_1 : \left\{ \begin{array}{l} \rho_i < 0 \text{ for } i = 1, 2, \dots, N_1, \\ \rho_i = 0 \text{ for } i = N_1 + 1, N_1 + 2, \dots, N \end{array} \right\}.$$

Hence, MW uses Fisher's (1932) result to derive tests that combine the p-values from the individual unit root in each cross-sectional unit. If the p-value from individual unit root test for cross-section  $i$  is defined as  $\pi_i$ , then under the null hypothesis of unit root for all  $N$  cross-sections, the test statistic is given by

$$P = -2 \sum_{i=1}^N \log(\pi_i) \rightarrow \chi^2_{2N}. \quad (4.2)$$

Pesaran (2007)'s cross section dependence IPS (CIPS) panel unit root test is based on a CADF regression, which filters out the cross-sectional dependence by augmenting the ADF regressions with the lagged cross-section mean and the lagged first differences of the cross sectional mean. Instead of basing the unit root tests on deviations from the estimated factors, Pesaran (2007) augmented the standard DF (or ADF) regressions with the cross-section averages of lagged levels and first-differences of the individual series. Panel unit root tests are then based on the simple averages of the individual cross-sectionally augmented ADF statistics or suitable transformations of the associated rejection probabilities. The individual CADF statistics or the rejection probabilities are then used to develop, for example, modified versions of the t-bar test in IPS, the P test in MW, and the Z test suggested by Choi (2001). The CADF regression estimates a dynamic linear heterogenous panel data model:

$$\Delta y_{it} = \alpha_{i0} + \alpha_{i1}t + \alpha_{i2}y_{i,t-1} + \alpha_{i3}\bar{y}_{t-1} + \sum_{j=0}^p d_{ij}\Delta\bar{y}_{t-j} + \sum_{j=1}^p \delta_{ij}\Delta y_{i,t-j} + \varepsilon_{it}. \quad (4.3)$$

The error term in equation (4.3) is assumed to have an unobserved one-common-factor structure accounting for cross sectional correlation and an idiosyncratic component. Let,  $\tilde{t}_i$  denote the t-ratio for  $\alpha_{i2}$  in the above regression. Then the CIPS test statistic is derived as:

$$\text{CIPS} = N^{-1} \sum_{i=1}^N \tilde{t}_i \quad (4.4)$$

See Pesaran (2007) for full derivation. The null and alternative hypothesis for CIPS test are

$$H_o : \alpha_{i2} = 0 \text{ for } i = 1, 2, \dots, N,$$

and

$$H_1 : \left\{ \begin{array}{l} \alpha_{i2} < 0 \text{ for } i = 1, 2, \dots, N_1, \\ \alpha_{i2} = 0 \text{ for } i = N_1 + 1, N_2 + 2, \dots, N. \end{array} \right\}$$

### 4.3.2 Pedroni and Westerlund Tests

In panel cointegration literature residual-based and system approaches have been suggested. Residual-based tests typically employ non-parametric procedures to model the residual serial correlation in the error correction terms, while vector auto-regressions (VAR) are employed in the development of system approaches. Two widely used residual-based panel cointegration tests are those suggested by Pedroni (1999, 2004) and Kao (1999) and the system approach is suggested by Larsson et al. (2001). Monte Carlo comparison by Gutierrez (2003) shows that in homogeneous panels, Kao's (1999) test have higher (lower) power than Pedroni's (1999) test when a small-T (high-T) are included in the panel. Gutierrez (2003) also shows that both these tests outperform Larsson et al.'s (2001) test. This study uses 37 years of monthly data and thus employs Pedroni's residual-based panel cointegration technique.

Pedroni's (1999, 2004) test is the extension of Engle and Granger's (1987) cointegration test for a single cross-section unit. The Engle and Granger cointegration test is based on the examination of the residual of a spurious regression performed using variables integrated of order one,  $I(1)$ . If the variables are cointegrated, then the residual will be  $I(0)$  and if the variables are not cointegrated, then residual will be  $I(1)$ . Pedroni proposes tests for cointegration that allows for heterogeneous intercepts and trend across cross-section units. For two  $I(1)$  variables  $x$  and  $y$ , consider the following regression

$$y_{it} = \alpha_i + \delta_i t + \beta_{1i} x_{1it} + \beta_{2i} x_{2it} + \dots + \beta_{Mi} x_{Mit} + e_{it} \quad \text{for } t = 1, 2, \dots, T; i = 1, 2, \dots, N; m = 1, 2, \dots, M. \quad (4.5)$$

The parameters  $\alpha_i$  and  $\delta_i$  allow for the possibility of member specific fixed effects and deterministic trends, respectively. The slope coefficients  $\beta_i$  are also permitted to vary by individual, so that in general the cointegrating vectors may be heterogeneous across members of the panel. To test whether the residuals are stationary, the following auxiliary regressions are estimated for each cross-section unit:

$$e_{it} = \rho_i e_{it-1} + u_{it} \quad (4.6)$$

$$e_{it} = \rho_i e_{it-1} + \sum_{j=1}^{\rho_i} \psi_{ij} \Delta e_{it-j} + v_{it} \quad (4.7)$$

Against the null hypothesis of no cointegration ( $H_0 : \rho_i = 0$ ), there are two alternative hypotheses, (i) the homogeneous alternative [ $H_1 : (\rho_i = \rho) < 1, \text{ for all } i$ ], also called within-dimension test or panel statistic test and, (ii) the heterogeneous alternative ( $H_1 : \rho_i < 1, \text{ for all } i$ ), also called between-dimension or groups mean panel statistic test. The within dimension tests consist of four statistics, namely, panel v-statistic, panel p-statistic, panel PP-statistic, and panel ADF-statistic. These tests take into account common time factors and allow for heterogeneity across panel members. The between-dimension tests include three statistics: group p-statistic, group PP-statistic, and group ADF-statistic. All seven tests are distributed asymptotically as standard normal. Among the seven tests, only the panel v-statistic is a right-sided test where large positive values reject the null of no cointegration. Conversely, large negative values reject the null hypothesis of no cointegration for the remaining tests. The panel cointegration test statistic  $\mathbf{N}_{N,T}$  is constructed from the residuals from any of the auxiliary regressions as in equations (4.6) and (4.7). A total of 11 statistics are generated with varying degrees of size and power for different  $N$  and  $T$  values. Pedroni shows that the standardized statistic is asymptotically normally distributed,  $\frac{\mathbf{N}_{N,T} - \mu\sqrt{N}}{\sqrt{v}} \Rightarrow N(0,1)$ , where  $\mu$  and  $v$  are Monte-Carlo generated adjustment terms.

For comparison purposes, a relatively new cointegration test proposed by Westerlund (2007) is employed on the data. One attraction of this new cointegration test is that it handles the problem of cross-sectional dependence by bootstrapping the critical values of the test statistics. Using an error correction setup, this framework proposes four test statistics: two are designed to test the alternative that the panel is cointegrated as a whole, while the other two are designed to test the alternative that variables in at least one cross-section unit are cointegrated. The former two statistics are referred to as group mean statistics, while the latter two are referred to as panel

statistics. The group mean statistics are constructed using three steps. The first step is to estimate a conditional error correction model:

$$\Delta y_{it} = \delta'_i d_t + \alpha_i y_{it-1} + \lambda'_i x_{it-1} + \sum_{j=1}^{p_i} \alpha_{ij} \Delta y_{it-j} + \sum_{j=0}^{p_i} \gamma_{ij} \Delta x_{it-j} + e_{it} \quad (4.8)$$

The second step involves estimating the error correction parameter  $\alpha_i(1)$  and the third step is to compute the group mean statistics as follows:

$$G_\tau = \frac{1}{N} \sum_{i=1}^N \frac{\hat{\alpha}_i}{SE(\hat{\alpha}_i)} \quad \text{and} \quad G_\alpha = \frac{1}{N} \sum_{i=1}^N \frac{T\hat{\alpha}_i}{\hat{\alpha}_i(1)}. \quad (4.9)$$

A three-step procedure is also involved to implement the panel statistics. In this part, the first step is the same as for the group mean statistics. The common error correction parameter and its standard error are estimated in the second step. The final step is to compute the panel statistics:

$$P_\tau = \frac{\hat{\alpha}}{SE(\hat{\alpha})} \quad \text{and} \quad P_\alpha = T\hat{\alpha}. \quad (4.10)$$

See Westerlund (2007) for full derivation.

#### 4.4 Data and Basic Statistics

This study uses two different panels of 12 countries. The first panel (Panel 1) has the British pound sterling (GBP) as the numeraire currency, while the second is the U.S dollar-based panel (Panel 2). Nominal exchange rates and the price levels are all monthly observations transformed in natural logarithms. All data are from the International Monetary Fund's International Financial Statistics through datastream. The euro is excluded from this analysis for its limited period of existence. For the first panel, the sample consists of the Canadian dollar (CND), Chilean peso (CLP), Indonesian rupiah (IDR), Japanese yen (JPY), Malaysian ringgit (MYR), Pilipino peso (PHP), South African rand (ZAR), South Korean won (KRW), Singapore dollar (SGD), Swiss franc (CHF), Thai baht (THB) and U.S. dollar (USD), all denominated in British pound sterling (GBP). The countries were chosen for purposes of comparison with results from earlier chapters. Consumer price index (CPI) is used as the measure of inflation. The U.S. dollar-base replaces GBP in the second panel. All data are appended at the end of this chapter.

## 4.5 Empirical Results

Log real exchange rates are calculated as  $y_{it} = s_{it} - p_{it} + p_{gbpt,ust}$ , where  $s_{it}$  is the log of exchange rate of country  $i$ th currency in terms of GBP (for the first panel) and U.S. dollar (for the second panel),  $p_{it}$  are logarithms of consumer prices indices in country  $i$ , and  $p_{gbpt,ust}$  are logarithms of consumer price indices of the UK and the USA, respectively (used as foreign price levels for the two panels). MW test results on real exchange rate along with CIPS test results for both panels are reported in the first two rows of Table 4.1. Note that MW test is carried out using both ADF and PP procedures. In the case of ADF, the optimum lag length is chosen on the basis of Schwartz Information Criteria (SIC) and in case of PP, Newey-West bandwidth is selected using Bartlett kernel. The null hypothesis is that all of the series contain unit roots and the alternative hypothesis is that all of the series are stationary. As can be seen, the results of both MW and CIPS tests indicate that the null hypothesis of a unit root cannot be rejected for both panels. This result is consistent with Pesaran (2007) and others. Pesaran (2007) found unit root in their test. While discouraging for PPP, this result is not overly surprising as the data used here are monthly, and that the panels are relatively smaller in size and a mixed bundle of countries from across the world.

The full-sample results may be sensitive to the selection of the countries in the panels. As a further check, panels are divided into three subgroups based on country characteristics such as their geographic locations and the levels of economic development. Accordingly, for Panel 1, Canada, Japan, Switzerland and the USA are put into the first subgroup; Indonesia, Malaysia, Philippines, Singapore, South Korea and Thailand constitute the second subgroup; and the remaining two outlying countries, namely, Chile and South Africa make up for the third subgroup. For Panel 2, everything remains the same except that the USA is substituted for the UK.

Table 4.1 also presents the unit root test results of panels in sub-groups. As can be seen, the full-sample and sub-sample results are very similar. None of the test statistics are significant at conventional levels, implying a rejection of stationarity of the real exchange rates in panels. Consequently, these results do not lend support to PPP.

As the tests for unit roots in real exchange rates may not be adequate for the empirical test of PPP, the two panel cointegration tests as discussed above are implemented. Before testing for cointegration, the first step is to check the order of integration of both the nominal exchange rate and the relative price level, as they need to be I(1) in levels for cointegration purposes. This is done using the same two panel unit root tests already employed as above (namely, MW and CIPS tests). The results reported in Table 4.2 show that the nominal exchange rate and relative price level appear non-stationary for both panels under MW and CIPS tests. Consequently, we can proceed to test for cointegration between these variables. Note that these variables are found to be stationary at 1 percent level when conducted the tests on their first differences (results not reported here for brevity).

**Table 4.1: Panel unit root tests on real exchange rates: sub-samples**

Panel/sub-group	ADF based MW	PP based MW	CIPS
Panel 1: Full Sample	12.37 (0.97)	14.38 (0.94)	1.40 (0.92)
Panel 2: Full Sample	10.04 (0.99)	11.57 (0.98)	0.35 (0.64)
Panel 1: 1 <sup>st</sup> sub-group	5.54 (0.69)	6.07 (0.64)	0.27 (0.61)
Panel 2: 1 <sup>st</sup> sub-group	3.73 (0.88)	4.27 (0.83)	1.13 (0.87)
Panel 1: 2 <sup>nd</sup> sub-group	9.16 (0.69)	7.43 (0.83)	-0.80 (0.21)
Panel 2: 2 <sup>nd</sup> sub-group	7.21 (0.84)	7.45 (0.83)	-1.25 (0.11)
Panel 1: 3 <sup>rd</sup> sub-group	0.29 (0.99)	0.31 (0.99)	0.91 (0.82)
Panel 2: 3 <sup>rd</sup> sub-group	0.35 (0.99)	0.39 (0.98)	1.28 (0.90)

Notes: The numbers in parenthesis are p values. The reported test statistics are given by equations (4.2) and (4.4) for MW and CIPS tests, respectively, with intercept and trend included in all cases.

**Table 4.2: Panel unit root tests on nominal exchange rate and relative price level: full sample**

Variables (Panels)	ADF based MW	PP based MW	CIPS
NER (Panel 1)	14.94 (0.92)	16.39 (0.87)	0.45 (0.67)
RPL (Panel 1 )	22.47 (0.55)	48.27 (0.00)	1.27 (0.90)
NER (Panel 2)	11.66 (0.98)	11.66 (0.98)	-1.31 (0.10)
RPL (Panel 2)	16.83 (0.86)	25.40 (0.38)	1.96 (0.97)

Notes: NER = Nominal exchange rate; RPL = Relative price level. See notes to Table 4.1

Pedroni's panel cointegration test is first conducted. As discussed in Section 4.3, this procedure tests for the null of no cointegration using seven test statistics. The results of these seven test statistics are reported in Table 4.3. As can be seen, the panel rho-statistics for full sample and 1<sup>st</sup> sub-sample in Panel 1 are significant at 10% and 5% respectively. However, the group rho-statistics for Panel 1 is not significant at any

level. None of the test statistics are significant for Panel 2. Thus, these results indicate that the Pedroni test has rejected panel cointegration between the exchange rate and inflation differential, indicating a rejection of PPP.

**Table 4.3: Pedroni's panel cointegration tests**

Panel 1				
	Full Sample	First Sub-group	Second Sub-group	Third Sub-group
Panel v-statistic	2.31**	1.15	1.45*	1.60*

Group ADF-statistic	1.76	0.91	1.60	0.28

Note: \*, \*\*, \*\*\* represents the significance level at 10%, 5% and 1% respectively.

To check if the nominal exchange rate and relative price level are cross-sectionally independent or not, Pesaran's (2004) cross-section dependence (CD) test is done and the results are presented in Table 4.4. As can be seen, the p- values are close to zero, which implies that the null hypothesis of no cross-sectional dependence is strongly rejected. As there is evidence of cross-sectional dependence, it may be worthwhile to take this into account in examining the long-run relationship between the exchange rate and relative price level.

The panel cointegration test proposed by Westerlund (2007) accommodates the issue of cross dependence. As already mentioned, this test handles the problem of cross-sectional dependence by bootstrapping the critical values of the test statistics. The null hypothesis of this test is no cointegration. If the null is rejected, then there is evidence of long-run or cointegrating relation between the variables in question, which will provide evidence of weak form of PPP to hold. Tables 4.5 and 4.6 report

**Table 4.4: Average correlation coefficients and Pesaran's CD test**

Panel 1						
	Nominal Exchange Rate			Relative Price Level		
	CD test	p-value	Correlation	CD test	p-value	Correlation
Full Sample	34.51	0.00	0.56	-6.35	0.00	0.78

Note: Under the null hypothesis of cross-section independence  $CD \sim N(0,1)$

the results of this cointegration test for Panel 1 and Panel 2, respectively. Information criterion AIC is set to be used to choose optimal lag and lead lengths for each series and the Bartlett kernel window width is set according to  $4(T/100)^{2/9}$  (See, Westlund, 2008) Column (4) of the table reports the p-value and column (5) reports the bootstrapped p-values with 1000 replications. Test results show that, even with bootstrapping, the null of no cointegration between nominal exchange rate and relative price level cannot be rejected at conventional significance levels. Given these results, it may not be worthwhile to pursue the usual next step in using fully modified OLS (FMOLS) or dynamic OLS (DOLS).

As a final check, conventional unit root tests on real exchange rates are conducted on an individual country basis and the results are presented in Tables 4.7. As can be seen from Table 4.7, in both panels the statistics for only Switzerland and Chile tend to be significant, while the rest of the sample fails the stationarity tests.

Chile	-4.18(0.01)	-3.72(0.02)	-4.07(0.01)	-3.81(0.02)

As a pre-requisite to cointegration test, the unit root for nominal exchange rates and relative prices in levels are tested and the results are presented in Table 4.8. As can be seen, the results are very mixed. For Panel 1, 5 out of 13 countries' CPI differential are stationary at level. The countries are Canada, the USA, Switzerland, Chile.

Malaysia and Chile. For Panel 2, CPI differential of Japan, UK, Switzerland, Malaysia and Chile are I(0). In such scenario conducting a cointegration test will lead to spurious results, hence the usual next step of testing for cointegrating relationship is dropped.

Overall, the results in this section tend not to provide support to PPP. While this evidence is at variance with several studies employing panel techniques (for example, Alba and Papell, 2007), it is consistent with a set of other studies (for example, Papell and Theodoridis, 2001). It is to be noted that the number of countries included in the panel for this chapter is relatively small and very mixed. Thus, the evidence here may lend support to the notion that panel unit root tests are sensitive to the selection of series included in the panel (Chortareas and Kapetanios, 2009).

**Table 4.8: Unit root results of individual countries: nominal exchange rates and inflation differentials**

	Panel 1				Panel 2

Note: p-values has been reported. \*, \*\* and \*\*\* represents significance at 1%, 5% and 10% respectively.

### Conclusion:

As far as I am aware, this chapter is the first comprehensive investigation on PPP using more than one the panel data approach simultaneously, specifically, it focused on the potentially non-stationary nature of the panel. USD is chosen, as it is the most popular currency base. We also conducted the same analysis using GBP as base currency to examine the robustness of results. This chapter has systematically

provided a re-examination of the empirical content of PPP for a mixed bundle of 12 currencies using panel data techniques. Both panel unit root tests and panel cointegration tests have been employed. For panel unit root tests, MW and CADF, and for panel cointegration tests, Pedroni and Westurlund frameworks have been used with the British pound sterling (GBP) as the numeraire currency. Results are then compared with a U.S. dollar-based panel. Overall, results do not lend empirical support to PPP which is consistent with the previous chapter. Results also indicate that alternative methodologies and numeraire currencies do not tend to make any difference in the results. These results may be attributable to the issues arising out the selection of series included in the panel, cross section dependence, cross integration and so on which are currently the focus of intense research in the literature.

## Appendix to Chapter 4

This appendix contains the log of nominal exchange rates (US dollar as numeraire) and consumer price index (CPI) data used in this chapter. The exchange rate and CPI are for the period 1979(M1) – 2014(M5) and 1973(M1)-2014(M4) respectively. As mentioned earlier, same CPI data have been used in previous chapter with slightly lesser cut-off (1973 M1 – 2013 M4). Table A4.1 contains the log of nominal exchange rate data for 12 countries. Table A4.2 contains the log of CPI data of all the 13 countries (including numeraire country).

**A4.1: Nominal exchange rates (USD as numeraire, in logarithm): 12 countries 1979(M1) – 2014(M5)**

# **Chapter 5**

## **Purchasing Power Parity and Divisia Index Numbers**

---

### **5.1 Introduction**

This chapter is a follow-up of the previous chapter where alternative panel data methods were employed to test purchasing power parity (PPP). The empirical results as reported in the previous chapter do not provide clear-cut evidence in support of PPP for a mixed bundle of currencies for the period spanning over the last three decades. The purpose of this chapter is to provide a further check on these results, this time using a Divisia index approach. Note that this approach has the similarity with the panel data methods in that it is based on the experience of several countries simultaneously, rather than looking at pairs of countries in isolation from the rest of the world.

Divisia index numbers possess desirable index number properties and are widely used in production and consumption economics (Thiel, 1975/76, Section 3.7). They can be interpreted and estimated as regression coefficients under a plausible error specification (see, Clements and Izan, 1981). Over the last decade or so, a Divisia approach has become quite popular in energy economics for aggregating electricity and fuels, as well as to decompose energy intensity (see, such as, Choi and Ang, 2012). Manzur (1990) introduces a Divisia index approach to the PPP literature. He sets up an analytical framework to show how Divisia index numbers apply to PPP and derives a set of restrictions based on Divisia index numbers to test PPP. The approach is simple and flexible in that it provides a test of PPP for each observation of the sample period, whereas the regression methods provide a test for only the entire period. Applying this methodology to the quarterly data for the Group of Seven (G-7) countries over the 1970s and 1980s with the U.S. dollar as the reference country, Manzur's results indicate that PPP does not hold up in the short run, but it works fairly well as a long-run proposition.

This chapter provides a re-examination of PPP based on Divisia index numbers, using quarterly data spanning over more than three decades for a mixed bundle ten countries. The original intention was to use the same sample with same frequency of

observations (monthly) as those in the previous chapter, but that has not been possible due to GDP data availability issues. While this chapter draws on Manzur (1990), it differs from that paper in respect of sample countries and time periods. The present study also uses the British pound sterling together with the U.S. dollar as base currencies. Overall, consistent with Manzur (1990), the results are very encouraging for PPP as a long-run proposition.

Since PPP is already introduced in the previous chapters, this chapter is relatively shorter, focusing mainly on the results, and organized as follows. In Section 5.2, a skeletal analytical framework abstracted from Manzur (1990) is given. This section also describes the data used in this study. Empirical results are contained in Section 5.3, followed by some additional results in the following section. The last section concludes the chapter.

## 5.2 Test Design and Data

Let  $p_i$  and  $q_i$  be the GBP (British pound sterling) price and quantity of a good purchased from country  $i$ ,  $M = \sum_{i=1}^n p_i q_i$  be the total cost of the bundle of goods purchased from  $n$  countries,  $\omega_i = p_i q_i / M$  be the  $i$ th budget share and let  $\bar{\omega}_i$  be the arithmetic average of  $\omega_i$  over the current and previous periods. If  $p_i'$  is the domestic currency price and  $s_i$  is the  $i$ th exchange rate (defined as the domestic currency cost of GBP1), then  $p_1 = p_1'$  as  $s_1 = 1$ .

The first-order Divisia moments are given by

$$\Pi_t = \sum_{i=1}^n \bar{\omega}_{it} dp_{it}, \quad \Pi_t' = \sum_{i=1}^n \bar{\omega}_{it} dp_{it}', \quad \Psi_t = \sum_{i=1}^n \bar{\omega}_{it} ds_{it}, \quad (5.1)$$

where  $d$  is the log-change operator ( $dx_t = \log x_t - \log x_{t-1}$ ),  $\Pi_t$ ,  $\Pi_t'$  and  $\Psi_t$  are the Divisia indexes of GBP price levels, domestic currency price levels and exchange rates, respectively. Similarly, Divisia variances are given by

$$\sigma_t^p = \sum_{i=1}^n \bar{\omega}_{it} (dp_{it} - \Pi_t)^2, \quad \sigma_t^{p'} = \sum_{i=1}^n \bar{\omega}_{it} (dp_{it}' - \Pi_t')^2, \quad \sigma_t^s = \sum_{i=1}^n \bar{\omega}_{it} (ds_{it} - \Psi_t)^2 \quad (5.2)$$

where,  $\sigma_t^p$ ,  $\sigma_t^{p'}$  and  $\sigma_t^s$  are the variances of GBP price levels, domestic currency price levels, and exchange rate changes, respectively. Divisia co-variances are defined as

$$\sigma_t^{ps} = \sum_{i=1}^n \bar{\omega}_{it} (dp_{it} - \Pi_t) (ds_{it} - \Psi_t), \quad \sigma_t^{p's} = \sum_{i=1}^n \bar{\omega}_{it} (dp'_{it} - \Pi'_t) (ds_{it} - \Psi_t) \quad (5.3)$$

where  $\sigma_t^{p's}$  and  $\sigma_t^{ps}$  are the co-variances of domestic-currency price levels to exchange rate changes and the GBP price levels to exchange rates changes, respectively.

The relative version of PPP states that the percentage change in the exchange rate is equal to the inflation differential:

$$ds_{it} = dp'_{it} - dp_{lt} + \varepsilon_{it}, \quad (5.4)$$

where  $\varepsilon_{it}$  is the deviation from PPP. Under PPP, the deviation  $\varepsilon_{it}$  is zero. Equation (5.4) together with equation (5.1) yields

$$\Psi_t = \Pi'_{it} - dp_{lt} + E_t, \quad (5.5)$$

where  $E_t = \sum_{i=1}^n \bar{\omega}_{it} \varepsilon_{it}$  is the Divisia mean (or weighted mean) of the deviations from PPP. Equation (5.5) states that the  $n$ -country average change in exchange rates is equal to the difference between the  $n$ -country average inflation rate in terms of domestic currencies and the average inflation rate in the UK, plus an average deviation. As  $\varepsilon_{it} = E_t = 0$  under PPP, it implies that

$$ds_{it} - \Psi_t = dp'_{it} - \Pi'_{it} + \varepsilon_{it} - E_t. \quad (5.6)$$

Under PPP,  $\varepsilon_{it} = E_t = 0$ . Similarly, using equations (5.1)-(5.6), the following conditions obtain:

$$\sigma_t^s = \sigma_t^{p'} = \sigma_t^{p's} \quad (5.7)$$

$$\sigma_t^p = \sigma_t^{ps} = 0. \quad (5.8)$$

and

$$\rho_t^{p's} = 1. \quad (5.9)$$

Equations (5.7) and (5.8) state that under PPP (i) exchange rates and domestic-currency price variances and their co-variance all coincide; and (ii) the variance of GBP prices and the co-variance between exchange rates and GBP prices both vanish. According to equation (5.9) domestic prices and exchange rates are perfectly

correlated under PPP. See Manzur (1990) for a step-by-step derivation of this framework.

The analysis in this chapter is carried out using n=10 countries, namely, Australia, Canada, Japan, the Philippines, Singapore, South Korea, South Africa, Switzerland, and the USA, with the UK as the reference country. Additional results are provided subsequently with the UK substituted by the USA. The data are quarterly, for the period from 1980 (4) to 2014 (1) (as late as available at the time of concluding this chapter). Domestic prices for each country ( $p_i$ ) are measured by consumer prices, and gross domestic product (GDP) shares are used for the weights ( $\omega$ ). All data are from IMF's International Financial Statistics (IFS) through DataStream and appended at the end of this chapter.

### 5.3 Empirical Results

Table 5.1 gives a summary of the data. As the data in this table refer to averages over more than three decades, they can be used for analysing the long run relationship between exchange rates and prices. PPP implies that exchange rate changes should coincide with inflation differentials. It is observed from the second

**Table 5.1: Summary statistics of quarterly exchange rates, inflation rates and GDPs (all in log-changes): 10 countries, 1981(Q1)-2014(Q1)**

Country	Average Exchange rate log-change $ds_i$	Average price log-change $dp_i$	Average inflation differential $Dp_i - Dp_1$	Mean GDP share. $\bar{\omega}$
(1)	(2)	(3)	(4)	(5)
UK		0.97		2.42
Australia	-0.09 (0.06)	1.02	0.04 (1.00)	0.87
Canada	-0.33 (0.05)	0.75	-0.23 (0.81)	5.53
Japan	-0.78 (0.07)	0.18	-0.79 (0.67)	26.73
Switzerland	-0.80 (0.05)	0.44	-0.53 (0.84)	0.52
USA	-0.27 (0.05)	0.76	-0.21 (0.78)	61.84
Singapore	-0.65 (0.05)	0.50	-0.48 (1.00)	0.15
Philippines	1.09 (0.07)	1.95	0.97 (2.47)	0.00
South Korea	0.09 (0.08)	1.06	0.08 (1.06)	0.80
South Africa	1.72 (0.08)	2.20	1.23 (1.24)	1.15

Note: All entries are multiplied by 100. Standard deviation in parenthesis

and fourth column of Table 5.1 that these two variables are quite closely related for the sample countries. This relation can be seen more clearly when we plot the

exchange rate changes against the inflation differentials, as in figure 5.1. As can be seen, the points are scattered around a  $45^0$  line, suggesting a fairly close relationship between exchange rates and national price levels over the longer term.

**Figure 5.1: Average exchange rate log-change against average inflation differential: long-run data**

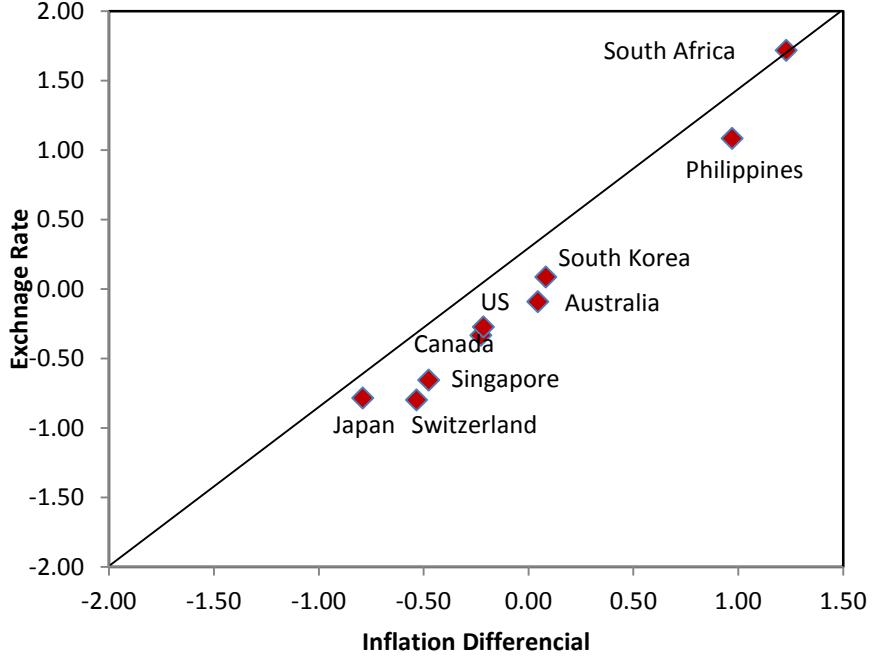

Table 5.2 gives the first- and second-order Divisia moments of exchange rate and prices computed from the data in Table 5.1. The first column of the table gives the Divisia index of exchange rates, defined by equation (5.1). We substitute into this equation the averages of  $ds_{it}$  and the averages of  $\bar{\omega}_{it}$ , given in the second column and the last column, respectively, of Table 5.1. A similar procedure is used for the application of the other measures to the long-run data. The second and third columns of Table 5.2 present the Divisia indexes for prices in domestic currencies and in GBP, defined also by equation (5.1). As can be seen exchange rate appreciated on average by 0.39 per cent per quarter, while prices in domestic currencies and in GBP increased by 0.63 per cent and 1.02 per cent, respectively. Using equation (5.5), we calculate the average deviation from PPP as  $E = \Psi - \Pi' + dp_1 = -0.39 - 0.63 + 1.02 = -0.05$  per cent per quarter (see column 5 of Table 5.2), which is not far away from zero (as required under PPP). Columns (6) to (8) give the Divisia variances of exchange rates and prices. The domestic-currency price-exchange rate co-variance and the corresponding correlation coefficient are presented in columns (9) and (10). The results in Table 5.2 reveal the following. First, the figure of 0.000055 for the variance

of prices in GBP, given in column (8), is small in comparison with the two other variances, 0.10 for  $\sigma^p$  and 0.11 for  $\sigma^s$ . This provides support to the prediction contained in equation (5.8) that  $\sigma^p = 0$  under PPP. Second, the figures of 0.11 and 0.10 for the variances of exchange rates and domestic-currency prices, given in columns (6) and (7), are quite close together, again in accordance with the implication for PPP contained as in equation (7). Finally, column (10) reports the value of the domestic-currency price-exchange rate correlation coefficient as 0.98, which is obviously quite close to unity, the value implied by PPP (see equation (9)). In summary, the long-run data in this sample are consistent with the PPP hypothesis. This result is consistent with Manzur (1990) and several other more recent studies using panel data methods (see, Chortareas and Kapetanios, 2009 and Ramajo and Ferré, 2010, among others).

**Table 5.2: Divisia moments of exchange rates and prices:  
long run data**

Price Index				Variance of			price- exchange rate		
$\Psi$	$\Pi'$	$\Pi$	$dp_1$	$E$	$\sigma^\psi$	$\sigma^{\pi'}$	$\sigma^\pi$	$\sigma^{\pi'\psi}$	$\rho^{\pi'\psi}$
(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)
-0.39	0.63	1.02	0.97	-0.05	0.11	0.10	0.000055	0.10	0.98

Table 5.3 is the short-run (quarterly) version of columns (1) – (5) of Table 5.2. We present in column (2) the ten-country average exchange rate change and in column (3) the domestic-currency average inflation rate. Column (4) gives UK inflation and the Divisia mean of PPP deviations in column (5). As can be seen, on average exchange rates appreciated (relative to GBP) by about 0.01 per cent per quarter while domestic-currency prices increased by about 0.99 per cent. Prices in GBP rose by 0.98 per cent on average. Consequently, the average deviation from PPP is  $-0.01 - 0.99 + 0.98 = -0.01$  per cent per quarter, as indicated by the last entry in column (5).

Figure 5.2 is the time-series version of Figure 5.1 with  $\Psi_i$  replacing the average exchange rate change for country  $i$  and similarly for the inflation differentials. As can be seen, there is almost no relation between exchange rates and prices with quarterly data.

Figure 5.3 plots these two variables against time. This figure reveals little (if any) relationship on a quarter-to-quarter basis. Given the stationary nature of the returns. The unconditional mean can be interpreted as the long run change. This long-run, or underlying, change broadly approximates the inflation differential in Figure 5.3.

**Figure 5.2 Average exchange rate log-change against average inflation differential- short-run data**

**Figure 5.3: Time series of average exchange rate log-change and average inflation differential- short-run data**

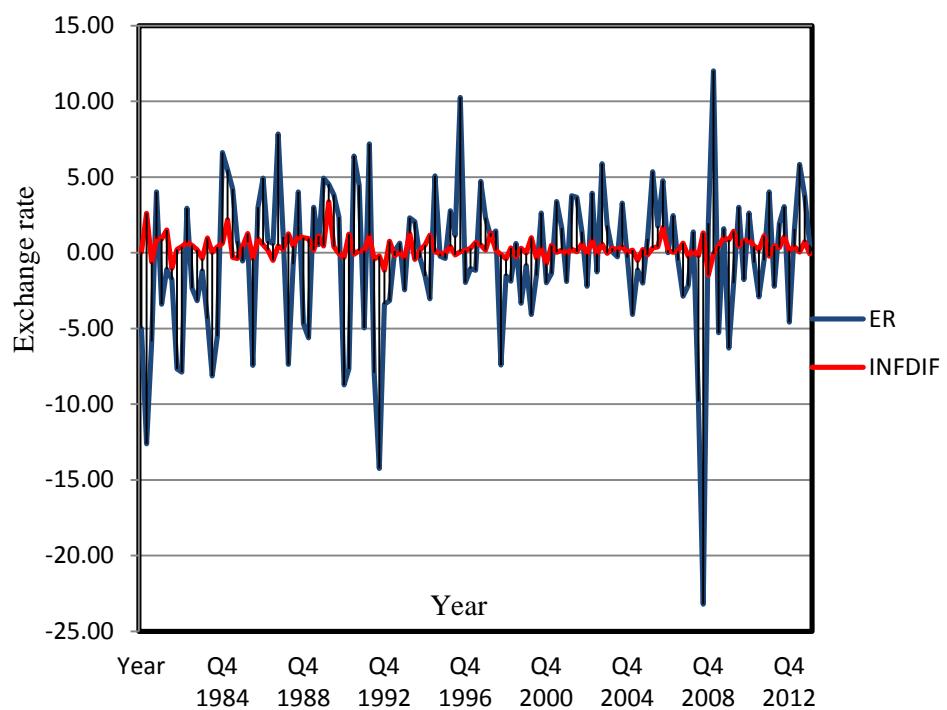

Figure 5.4 plots  $\Psi_t$  against  $E_t$  indicating that most of the deviations from PPP come from the nominal exchange rate changes.

**Figure 5.4: Average exchange rate log-change against average purchasing power parity deviation- short-run data**

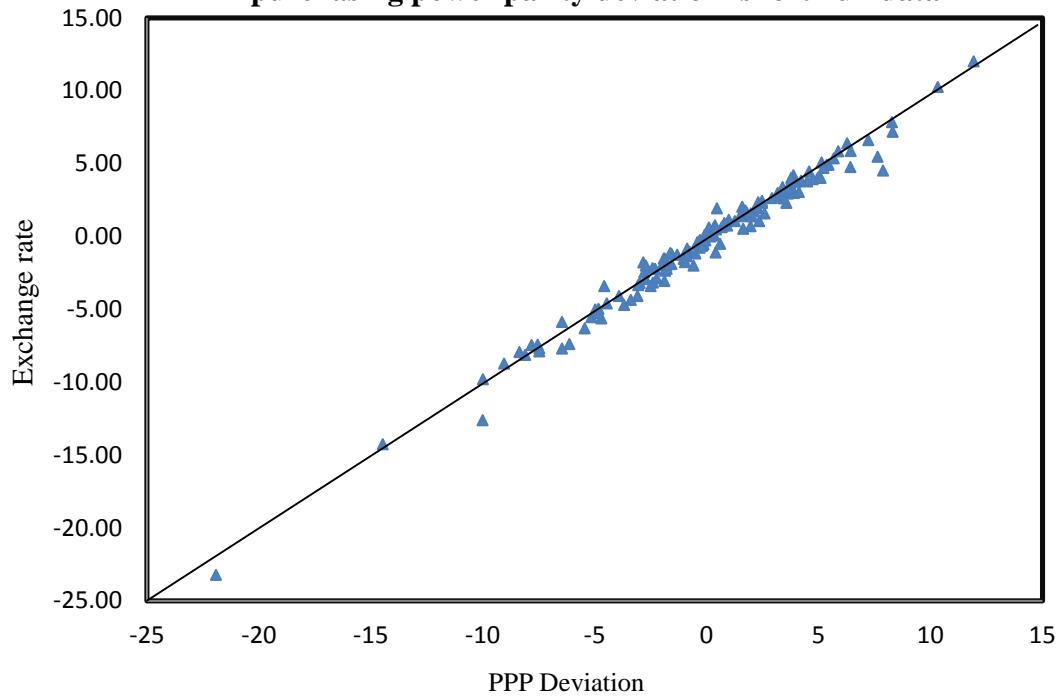

Table 5.4 is the quarterly version of columns (6)-(10) of Table 5.2. As can be seen, on average the ( $\sigma^s$ ), ( $\sigma^{p'}$ ) and ( $\sigma^p$ ) are far from each other and ( $\rho^{p's}$ ) is close to zero.

**Table 5.4: Divisia variances and co-variances of exchange rates and prices: short run data**

Notes: All entries are multiplied by 10,000 except those in the last column

As shown above, the short-run results indicate that PPP performs poorly. On the other hand, the long-run data are quite consistent with the PPP hypothesis. If PPP holds in the long run only, how long is the long run? Manzur (1990) handles this question by computing multi-period Divisia price-exchange rate correlations. For this purpose, rather than using changes in prices and exchange rates over one quarter as before, changes are used for over two quarters, three quarters and so on, up to the last quarter of the sample time period. Since these changes involve comparisons of periods which become further and further apart, they represent the transition from the short run to the long run. A similar exercise is carried out here and the results are presented in Table 5.5. Note that this table reports multi-period Divisia price-exchange rate correlations for up to 35 quarter-change for brevity. Each entry in this table is a Divisia price-exchange rate correlation for a given length of change. Thus, the entries under the first-quarter change coincide with those in the last column of Table 5.4. As can be seen, the correlations improve as one moves from left to right in Table 5.5. The last row of the table gives the averages of the correlation coefficients for the various lengths of changes. We plot these averages against the length of the change, as in Figure 5.5. It can be seen that the values increase with the length of the change and reach around 0.60 after about 20 quarters. Thus, the results tend to identify five years as being a broad measure of the length of the long run insofar as PPP is concerned.

In summary, the results based on the UK as the reference country indicate that the short-run variability in exchange rates does not reflect at all inflation differentials. This finding is in sharp contrast to the long-run results and is consistent with Manzur (1990).

#### 5.4 Additional Results

The results thus far have been based on exchange rates with GBP as the numeraire currency. For comparison purposes, this section presents results with computations re-done using the U.S. dollar as the numeraire currency. GDP shares are now recalculated with nominal GDPs converted into US dollars using the corresponding US dollar exchange rates. This section also presents results based on samples truncated into sub-groups with both GBP and U.S. dollar as numeraire currencies, respectively. The purpose of dividing the sample into sub-groups is to check if the results were to differ due to country characteristics such as, its size, location and the level of economic development. With GBP as the numeraire currency, the first sub-group consists of countries of the major currencies, namely, Australia, Canada, Japan,

Switzerland and the USA; the second sub-group has the remaining ones namely Singapore, Philippines, South Korea and South Africa. With the U.S. dollar as the numeraire currency, the USA is replaced by the UK in the first sub-group, while other things remaining the same.

Figure 5.6 is the U.S. dollar-version of Figure 5.1. As can be seen, this figure closely resembles Figure 5.1. Table 5.6 is an enlarged version of Table 5.2. In this enlarged table, full-sample and sub-group long-run results are presented with both GBP and the U.S. dollar as the numeraire currencies, respectively. Note that the entries reported in this table for the full sample under GBP are the same as those in Table 5.2. The results in Table 5.6 indicate that the sub-group results are very similar to the full-sample results under both GBP and the U.S. dollar as numeraire currencies, respectively. These results imply that the choice of the numeraire currency may not be important in so far as the long-run PPP is concerned.

## 5.5 Conclusion

This chapter has used a relatively simple methodology to test the purchasing power parity with data spanning over the last three decades. Following Manzur (1990), a set of test conditions are set up using the first- and second-order moments of prices and exchange rate across a mixed bundle of countries. This framework has provided an empirical test of PPP with both short-run (quarterly) and long-run data for the period 1981-2014. The results indicate that PPP does not hold up at all well in the short run. The evidence with the long-run data lends considerable support to PPP. The results also tend to identify five years as being a broad measure of the length of the long run as far as PPP is concerned. These results are consistent with the recent mainstream literature.

## Appendix to Chapter 5

This appendix provides the data quarterly exchange rate, CPI and GDP for the Australia, Canada, Japan, Switzerland, UK, US, Philippines, Singapore, South Korea and South Africa. The data are from International Financial Statistics (IFS) through Thomson Reuters Datastream. Tables 5.1-A5.10 present the data. GDP is reported in both domestic currency and in equivalent GBP. In Table A5.11 the arithmetic averages of the GDP shares (with GBP as numeraire) are given. Note that the U.S. dollar denominated data are not reported here.

## **Chapter 6**

### **Conclusion:**

---

This thesis has provided a systematic analysis of a set of key issues in exchange rate economics. It has empirically investigated topics including exchange rate volatility and its manifestations; the presence of nonlinearity in exchange rates; and the interaction between national price levels and exchange rates. The approach is analytical and empirical, employing formal econometric and modeling techniques to a wide range of up-to-date data on the major as well as developing countries. The issues covered in this study are among the most controversial in international finance. They raise questions about the degree to which domestic inflationary propensities and their transmission across countries are conditioned by the nature of the exchange rate regimes. These questions themselves concern the more fundamental problems of exchange rate determination, the degree of monetary independence and its implications for macroeconomic policy. The empirical analyses and results of this study are expected to contribute to an understanding of the intriguing questions regarding the nature of exchange rate dynamics; the role of nonlinearity, outlier and structural change in exchange rate returns; and the content of purchasing power parity (PPP), linking exchange rate instability with domestic inflation.

The thesis has started with Chapter 1, setting the stage for the other chapters to follow. This chapter has provided a skeletal background, using set of stylised facts. Chapter 2 has given a set of broad features of major exchange rates since the early 1970s, and compared these features with those of the 1960s. Also included was an analysis of whether these features were manifested in real interest rates and in commodity prices. The results have indicated that exchange rates are not as volatile as they are generally viewed. Note that this result is instructive in view of the popular intuition that exchange rates are excessively volatile.

The next three chapters may be viewed as the core work of this thesis. Chapter 3 has given a systematic treatment of the time series properties of a mixed bundle of currencies since major currencies returned to the floating system in the early 1970s. The sample has included four major currencies and eight other relatively less-liquid currencies, all denominated in British pound-sterling. The purpose of including

relatively less liquid currencies is to compare and check if nonlinearity is more of a phenomenon for the currencies of less-developed countries. The results have indicated the presence of nonlinearity in exchange rates. However, the outliers and structural breaks have not been found to be significant in affecting the results.

Chapter 4 has provided a re-examination of the empirical content of PPP for a mixed bundle of 12 currencies using panel data techniques. Alternative panel unit root tests are implemented with the British pound sterling (GBP) as the numeraire currency. Results are then compared with a U.S. dollar-based panel. The panel unit root tests failed to provide support to PPP. The data are then analysed using alternative panel cointegration tests. The reason for this further analysis is that non-rejection of unit roots in real exchange rates does not necessarily imply a rejection of PPP. If nominal exchange rates and relative price levels are integrated of order one (in levels), then it is possible that these two variables may be cointegrated, implying a close relationship in the long run. Again, the results have not been encouraging for PPP. The sample consisting of 12 countries was then divided into 3 sub-groups to check if the results were sensitive to country characteristics. The results are mixed and the data tend to reject PPP. Chapter 5 has provided a further check on the results in Chapter 4, this time using a Divisia index approach. This approach has a similarity with the panel approach in the previous chapter in that it provides a test of PPP based on several countries jointly, rather than taking pairs of countries in isolation from the rest of the world. Using this framework, the short-run results indicate that the predictions of PPP do not hold up well. On the other hand, the long-run data are quite consistent with the PPP hypothesis. The results also identify five years as a broad measure of the length of the long run in so far as PPP is concerned.

In general, conclusions drawn in each chapter are consistent with the broad literature on these topics. However, the results in Chapters 4 and 5 are somewhat contrasting. This may be attributable to the difference in the data frequency used in the two chapters. Note that the choice of the data frequency used in these two chapters was dictated by the data availability. Given the puzzles in the results in these two chapters, it may be worthwhile to revisit these issues in future research.
