25 **Abstract.** In this contribution we analyze the single-frequency L5 positioning capabilities of  
26 the two regional satellite navigation systems IRNSS and QZSS, stand alone as well as  
27 combined. The positioning analysis is done for two different baselines, having a mix of  
28 receivers, providing ambiguity-float and ambiguity-fixed positioning for models with and  
29 without zenith tropospheric delay (ZTD) estimation. The analyses include a precision analysis  
30 of the observed signals as well as an analysis of the ambiguity resolution performance. This is  
31 done for both the multipath-uncorrected case as well as the multipath-mitigated case. It is  
32 shown that although single-system positioning performance is rather poor, the ZTD-fixed,  
33 single-epoch ambiguity success-rates (ASRs) are close to 100% when the two regional systems  
34 are combined, thus providing mm-to-cm level precision for instantaneous ambiguity-fixed  
35 positioning. When the ZTD is estimated as well, only a few additional epochs are needed to get  
36 the ASRs close to 100%.

38 positioning

39

## 40 **Introduction**

41 After the Japanese Quasi-Zenith Satellite System (QZSS) was realized as a four-satellite system  
42 in October 2017 (NSPS 2018a), the Indian Regional Navigation Satellite System (IRNSS), with  
43 the operational name of NavIC (Navigation with Indian Constellation), launched its eighth  
44 satellite in April 2018 (ISRO 2018). In addition to the first IRNSS satellite (IRNSS-1A), with  
45 failed onboard atomic clocks (<https://thewire.in/science/atomic-clock-rubidium-irNSS>) and  
46 located in inclined geosynchronous orbit (IGSO), there are four other IRNSS satellites located  
47 in the IGSO and another three in geostationary orbit (GEO), providing Standard Positioning  
48 Service (SPS) over the Indian landmass and Indian Ocean (Zaminpardaz et al. 2017). The L5  
49 signal (1176.45 MHz) is shared by both the QZSS and IRNSS.

50 Australia benefits from the dual-system L5 signals. Figure 1 shows the ground tracks of the  
51 IRNSS and QZSS satellites based on the combined multi-GNSS Experiment (MGEX)  
52 broadcast ephemeris (BRDM 2018, Montenbruck et al. 2017) on Day of Year (DOY) 77, 2018,  
53 which does not contain the IRNSS satellite I01 with failed onboard clocks and the newly April  
54 launched I09. The details of the satellites are given in Table 1. The repeat cycles of the satellites  
55 from both systems amount to about 1 sidereal day, the patterns shown in Figure 1 thus

56 approximately repeat after about 23 h 56 min. The left and right panels of Figure 2 illustrate  
 57 the percentages within a 24 h period that at least 6 and 8 QZSS/IRNSS satellites are visible  
 58 with an elevation angle above 10 degrees, respectively, and the number of the QZSS/IRNSS  
 59 satellites above the elevation mask as well as their sum for station CUT3 located in Perth,  
 60 Australia. It can be observed that in a large part of Australia, at least 8 satellites can be observed  
 61 during the entire day. In Perth, the number of the available satellites increases from about 4 in  
 62 standalone cases to about 8 in combined case.

63

64

65 **Fig 1** Satellite ground tracks. The blue and red lines represent the ground tracks of the IRNSS  
 66 and QZSS satellites, respectively. The plots were generated based on the combined Multi-  
 67 GNSS Experiment (MGEX) broadcast ephemeris (BRDM 2018, Montenbruck et al. 2017) on  
 68 DOY 77, 2018. Note that the IRNSS satellite I01 with failed onboard clocks and the newly  
 69 launched I09 were not contained in the combined broadcast ephemeris on this day and are not  
 70 shown in the plot

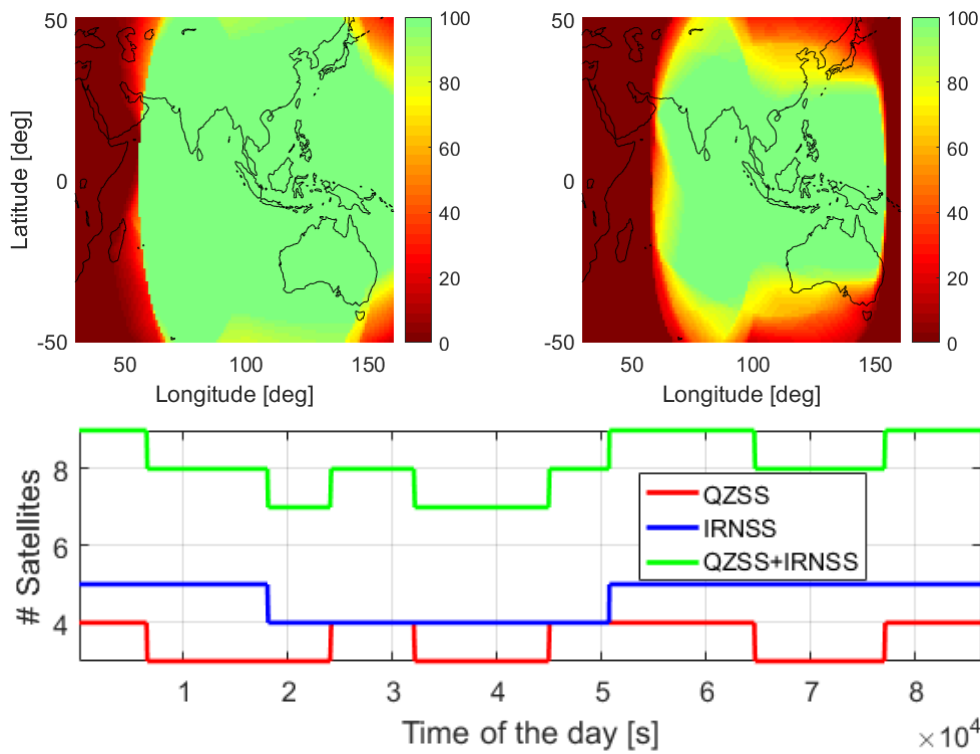

71

72 **Table 1** Information of the QZSS and IRNSS satellites (MGEX 2017a,b; Zaminpardaz et al.  
 73 2017)

Satellite	PRN	Orbit type	Launch date
QZS-1 (Michibiki)	J01	QZO	September 2010
QZS-2 (Michibiki-2)	J02	QZO	June 2017
QZS-3 (Michibiki-3)	J07	GEO	August 2017
QZS-4 (Michibiki-4)	J03	QZO	October 2017

IRNSS-1A	I01	IGSO	July 2013
IRNSS-1B	I02	IGSO	April 2014
IRNSS-1C	I03	GEO	October 2014
IRNSS-1D	I04	IGSO	March 2015
IRNSS-1E	I05	IGSO	January 2016
IRNSS-1F	I06	GEO	March 2016
IRNSS-1G	I07	GEO	April 2016
IRNSS-1I	I09	IGSO	April 2018

78 **Fig 2** Percentage color maps and number of visible satellites. Percentages within a 24 h period  
79 that at least 6 [top left] and 8 [top right] QZSS/IRNSS satellites are simultaneously visible  
80 above the elevation mask of 10 degrees, and the numbers of the QZSS and IRNSS satellites  
81 visible above the elevation mask as well as their sum for station CUT3 in Perth, Australia  
82 [bottom]. The plots were generated based on the combined MGEX broadcast ephemeris  
83 (BRDM 2018, Montenbruck et al. 2017) on DOY 77, 2018. Note that the IRNSS satellite I01  
84 with failed onboard clocks and the newly launched I09 were not contained in the combined  
85 broadcast ephemeris on this day and are not included in the plot. The colormaps in the top panel  
86 were generated based on a data sampling interval of 30 s

87

88 In recent years, several studies have been performed to analyze the signal characteristics of  
89 the IRNSS and QZSS signals (Hauschild et al. 2012; Nadarajah et al. 2016; Nie et al. 2015;  
90 Quan et al. 2016; Zaminpardaz et al. 2017, 2018). Zaminpardaz et al. (2017) gave both the  
91 undifferenced multipath-uncorrected and –corrected code and phase standard deviations in the  
92 zenith direction as well as the code-phase correlation coefficients for IRNSS and GPS L5  
93 signals. For triple-frequency QZSS signals on L1, L2 and L5, Zaminpardaz et al. (2018) showed  
94 the undifferenced zenith-referenced standard deviations as well as the phase between-frequency  
95 covariances. It was verified that the QZSS L5 code signals have higher precision than the L1  
96 and L2 code signals before and after multipath corrections.

97 As stand-alone systems respectively, the real-time kinematic (RTK) positioning results were  
98 shown and discussed in Zaminpardaz et al. (2018) based on triple-frequency data from 4 QZSS  
99 satellites and in Zaminpardaz et al. (2016) using L5 signals from 6 IRNSS satellites. Combining  
100 QZSS satellites with other GNSS like **GPS, Galileo and BDS**, RTK results were also studied  
101 in Odolinski and Teunissen (2017), Odolinski et al. (2015). In Nadarajah et al. (2016), the L5  
102 signals from IRNSS, GPS, Galileo and QZSS were combined for analysis of the RTK and  
103 attitude determination performances, however, based only on two IRNSS satellites (I01 and  
104 I02) and one QZSS satellite (J01). As the number of the satellites of both the IRNSS and QZSS  
105 has largely increased during recent years, taking advantage of Australia’s location, it is now  
106 possible to assess the ambiguity resolution and positioning performances using the  
107 QZSS/IRNSS combined L5 signals with more satellites (see Figure 2).

108 This contribution thus aims to study the potential of single-frequency L5 RTK positioning  
109 using the two regional satellite systems. We first introduce our observational model and then  
110 perform a signal analysis of the QZSS and IRNSS L5-code and -phase data for both the  
111 multipath-uncorrected and –corrected cases. This is followed by our ambiguity resolution and  
112 positioning analyses, first of a short baseline using identical receivers and no atmospheric  
113 delays, and then of a longer baseline, using mixed receivers. Our study includes both formal  
114 and empirical analyses of the ambiguity success-rates (ASRs) and positioning precision.

115

## 116 **Processing strategy**

117 For a single-frequency model, the expectation of the double-differenced (DD) observed-minus-  
 118 computed (O-C) terms of the code  $\Delta p$  and phase observations  $\Delta\phi$  of a single baseline can be  
 119 formulated as (Teunissen and Montenbruck 2017):

$$120 \quad \mathbb{E} \begin{bmatrix} \Delta p \\ \Delta\phi \end{bmatrix} = \begin{bmatrix} D_m^T G & 0 \\ D_m^T G & \lambda_j I_{m-1} \end{bmatrix} \begin{bmatrix} \Delta\rho \\ a \end{bmatrix} \quad (1)$$

121  
 122 with  $\mathbb{E}[\cdot]$  denoting the expectation operator. The matrix  $D_m^T$  is the differencing operator given  
 123 as  $D_m^T = [-e_{m-1}, I_{m-1}]$ , where  $m$  denotes the number of satellites. The term  $I_{m-1}$  denotes the  
 124 identity matrix of size  $m - 1$ . The vector  $\Delta\rho$  contains the geometry elements, i.e., the 3-  
 125 dimensional baseline increment  $\Delta x$  and, for baselines with a length of several kilometers, it may  
 126 also contain the between-receiver zenith tropospheric delay (ZTD) increment  $\Delta\tau$ . The a priori  
 127 tropospheric delays are computed with the Saastamoinen model (Saastamoinen 1972) and are  
 128 corrected in the O-C terms. The matrix  $G$  is given as  $G = [u^1, \dots, u^m]^T$ , with  $u^s$  denoting the  
 129 satellite-to-receiver unit vectors, and in case of the presence of  $\Delta\tau$ ,  $G =$   
 130  $[[u^1, \dots, u^m]^T, [g^1, \dots, g^m]^T]$ , with  $g^s$  denoting the elevation-dependent tropospheric  
 131 mapping function, here the Ifadis mapping function (Ifadis 1986). For baselines within 10 km,  
 132 we assume the tropospheric mapping functions of both receivers  $g_1^s$  and  $g_2^s$  to be the same, and  
 133 therefore we drop their subscript. The vector  $a$  represents the DD ambiguities in cycles, and  $\lambda_j$   
 134 denotes the wavelength of the frequency used for the processing, i.e. L5. We remark that for  
 135 each epoch, we select only one reference satellite and thus not a system-specific reference  
 136 satellite. By forming between-system double differences, we assume the differential inter-  
 137 system biases (ISBs) to be zero for baselines with the same receiver and antenna types (Odijk  
 138 et al. 2017). For baselines with mixed receiver types, the processing is only performed in  
 139 multipath-mitigated case, where the day-differenced observations are used. As the differential  
 140 ISBs are assumed to be constant over two consecutive days, they are considered removed  
 141 through multipath mitigation.

142 The dispersion of the DD O-C terms (1) is given as

$$143 \quad \mathbb{D} \begin{bmatrix} \Delta p \\ \Delta\phi \end{bmatrix} = \begin{bmatrix} D_m^T Q_p W^{-1} D_m & 0 \\ 0 & D_m^T Q_\phi W^{-1} D_m \end{bmatrix} \quad (2)$$

145 where the  $m \times m$  diagonal matrices  $Q_p$  and  $Q_\phi$  contain the undifferenced zenith-referenced  
 146 variances on L5 code and phase observations, respectively, for satellites of the corresponding  
 147 systems.  $D[\cdot]$  denotes the dispersion operator, and the inversed between-receiver weight matrix  
 148  $W^{-1}$  is given as

$$149 \quad W^{-1} = W_1^{-1} + W_2^{-1} = \text{diag}([w_1^1, \dots, w_1^m]^T)^{-1} + \text{diag}([w_2^1, \dots, w_2^m]^T)^{-1} \quad (3)$$

151 where  $\text{diag}(\cdot)$  denotes the diagonal matrix with the diagonal elements contained in  $(\cdot)$ . The  
 152 term  $w_r^s$  is the elevation-dependent exponential weighting function (Euler and Goad 1991):

$$153 \quad w_r^s = \left( 1 + 10 \exp\left(-\frac{e_r^s}{10}\right) \right)^{-2}$$

154 (4)

155 for which  $e_r^s$  denotes the elevation angle from receiver  $r$  to satellite  $s$  in degrees, and  $\exp(\cdot)$  is  
 156 the **natural** exponential function. In this study, the elevation mask is set to be 10 degrees.

157

## 158 **Measurement Setup**

159 In this study, the 1 Hz QZSS and IRNSS phase and code observations on L5 were collected  
 160 from receivers CUT3, CUBB, CUCC located in Curtin University, Perth, Australia and UWA0  
 161 located at the University of Western Australia, Perth, Australia. The very short baseline CUT3-  
 162 CUBB of around 4 m and the longer baseline CUCC-UWA0 of around 8 km (Figure 3) were  
 163 formed for the RTK processing. Receivers of the same type JAVAD TRE\_G3TH DELTA and  
 164 antennas of the same type TRM 59800.00 SCIS were used for the baseline CUT3-CUBB. For  
 165 the baseline CUCC-UWA0, mixed receiver and antenna types were used as shown in Table 2.

166

167

168 **Fig 3** Baselines used for the processing. The baseline CUT3-CUBB [top] of around 4 m and  
 169 the baseline CUCC-UWA0 [bottom] of around 8 km are located in Perth, Australia. Map data  
 170 [bottom] @ 2018 Google (Google Earth 2018)

171

172 **Table 2** Receiver and antenna types of the stations used for the processing

Station	Receiver type	Antenna type
CUT3	JAVAD TRE_G3TH DELTA	TRM 59800.00 SCIS
CUBB		
CUCC		
UWA0	SEPT POLARX5	JAVRINGANT_DM SCIS

173

174 In this contribution, days in March/April 2018 were used for analysis of the signal  
 175 characteristics and RTK processing. Figure 4 shows the skyplot of the IRNSS and QZSS  
 176 satellites for the station CUT3 on DOY 77, 2018. The skyplot was generated based on the  
 177 combined MGEX broadcast ephemeris on this day (BRDM 2018, Montenbruck et al. 2017).

178

179

180 **Fig 4** Skyplot of the IRNSS and QZSS satellites. The blue and red lines represent the skyplots  
 181 of the IRNSS and QZSS satellites for the station CUT3 on DOY 77, 2018, respectively. The  
 182 plot was generated based on the ground truth of station CUT3 and the combined MGEX  
 183 broadcast ephemeris (BRDM 2018, Montenbruck et al. 2017)

184

185 Figure 5 shows the Position Dilution of Precision (PDOP) of the baseline CUT3-CUBB for  
 186 QZSS-standalone, IRNSS-standalone and QZSS/IRNSS-combined cases on DOY 77, 2018.  
 187 The PDOP is calculated with:

$$188 \quad \text{PDOP} = \sqrt{\frac{\text{tr}\{(G^T D_m W_{DD} D_m^T G)^{-1}\}}{2}}$$

189 (5)

190 with

$$191 \quad W_{DD} = (D_m^T W^{-1} D_m)^{-1}$$

192 (6)

193 where  $\text{tr}\{\cdot\}$  denotes the trace of the matrix contained in  $\{\cdot\}$ . The term  $G$  contains here only the  
 194 satellite-to-receiver unit vectors, and the inversed between-receiver weight matrix  $W^{-1}$  can be  
 195 obtained with (3). We remark that the data used in this study went through a screening process  
 196 in the single point positioning (SPP) procedure and was afterwards checked for possible half

197 cycle problems after cycle slips. Gaps in Figure 5 are caused by time points with less than four  
 198 satellites or with PDOPs larger than 100, which are not used in the processing. **The maximal**  
 199 **PDOP in the combined case is about 8.7.**

200

201

202 **Fig 5** PDOP time series. The baseline CUT3-CUBB on DOY 77, 2018 was used for computing  
 203 the PDOPs in QZSS-standalone (red), IRNSS-standalone (blue) and QZSS/IRNSS-combined  
 204 (green) cases

205

206 **Stochastic Properties**

207 In this section, the L5 code and phase signals are analyzed for QZSS and IRNSS satellites in  
 208 multipath-uncorrected and –mitigated cases. The geometric ranges and the integer DD  
 209 ambiguities are assumed known and removed from the DD observations so that the remaining  
 210 DD residuals contain only the noise, multipath effects and for the baseline CUCC-UWA0 also  
 211 the DD atmospheric delays:

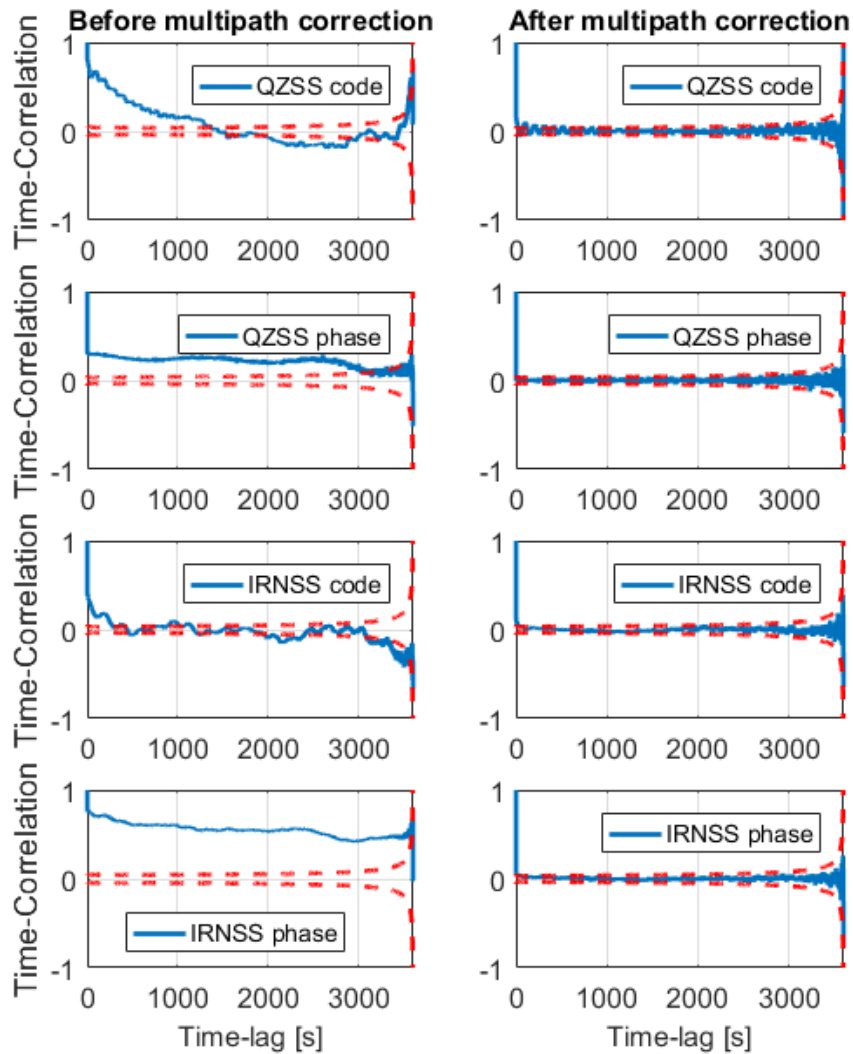

$$212 \begin{bmatrix} e_p \\ e_\phi \end{bmatrix} = \begin{bmatrix} p \\ \phi \end{bmatrix} - \begin{bmatrix} I_{m-1} & 0 \\ I_{m-1} & \lambda_j I_{m-1} \end{bmatrix} \begin{bmatrix} \rho \\ a \end{bmatrix} \tag{7}$$

213

214 where  $e_p$  and  $e_\phi$  represent the DD code and phase residuals, respectively, and  $p$  and  $\phi$  stand  
 215 for the DD code and phase observations, respectively. The vector  $\rho$  denotes the DD geometric  
 216 ranges. For the 4 m baseline CUT3-CUBB, the ambiguities were obtained with the single-epoch  
 217 baseline-known model, for which the DD geometric ranges computed from the ground truth  
 218 were removed from the DD phase observations, and the DD ambiguities were obtained by

219 rounding the residuals divided by the wavelength. For the 8 km baseline CUCC-UWA0, the  
220 referenced ambiguities were obtained with the stronger multi-epoch baseline-known model, for  
221 which the ambiguities are assumed to be constant in time. For multipath mitigation, the DD  
222 residuals on the subsequent day are subtracted from those on the processing day. A time shift  
223 of 4 min was considered by forming the day-to-day differences. Assuming that the satellite  
224 configuration approximately repeats on the subsequent day after shifting 4 min, the multipath  
225 is considered to be removed to a large extent. The remaining residuals contain thus for the 4 m  
226 baseline CUT3-CUBB mainly the noise, and for the 8 km baseline CUCC-UWA0 mainly the  
227 noise and the day-to-day DD atmospheric delays. Figure 6 shows the time correlation for the  
228 baseline CUT3-CUBB using 1 h data on DOY 75, 2018. The data on DOY 76 was used for  
229 multipath mitigation. The figures illustrate the influence of the multipath mitigation procedure  
230 on the time correlation of the observations. The large correlations were reduced to ignorable  
231 level after mitigating the multipath.

232

233

234 **Fig 6** Time correlation of the L5 signals of baseline CUT3-CUBB. The code and phase signals  
 235 from QZSS and IRNSS satellites from 00:04:00 to 01:03:59 in GPS Time (GPST) on DOY 75,  
 236 2018 were used for the plots before [left] and after multipath mitigation [right]. Data from  
 237 00:00:00 to 00:59:59 in GPST on DOY 76 of 2018 was used for multipath mitigation

238

239 Using the least-squares variance component estimation (LS-VCE) procedure (Amiri-  
 240 Simkooei et al. 2009; Teunissen and Amiri-Simkooei 2008), the undifferenced standard  
 241 deviations were computed in the zenith direction for L5 code and phase signals of QZSS and  
 242 IRNSS separately. For the 4 m baseline CUT3-CUBB, time points on DOY 75 and 76 (shifted  
 243 by 4 min for multipath mitigation) with observations from 4 QZSS satellites (J01, J02, J03,  
 244 J07) and 5 IRNSS satellites (I02, I03, I04, I05, I07) were used for signal analysis of QZSS and

245 IRNSS, respectively. For the 8 km baseline CUCC-UWA0, the data on DOY 70 and 71 was  
 246 used for signal analysis in the multipath-mitigated case. We note that by forming geometry-  
 247 free combination using L1 and L5 phase signals of the QZSS satellites, the ionospheric  
 248 behaviors for the QZSS satellites during the time epochs used for signal analysis on DOY 70  
 249 and 71 for baseline CUCC-UWA0 are mostly shown to be quiet. We thus ignored the DD  
 250 ionospheric delays for the 8 km baseline but considered only its DD ZTDs. For the baseline  
 251 CUCC-UWA0, the standard deviations for QZSS L5 signals were taken from Zaminpardaz et  
 252 al. (2018), and those for L5 IRNSS signals were calculated in multipath-mitigated case. We  
 253 remark that after multipath mitigation, the factor of  $\sqrt{2}$  caused by forming day-to-day  
 254 differences are included in the third and fourth columns. For the short baseline CUT3-CUBB,  
 255 the signal standard deviations of QZSS and IRNSS are found to be similar to those performed  
 256 for other short baselines of the same receiver/antenna type in Zaminpardaz et al. (2017, 2018),  
 257 when the factor of  $\sqrt{2}$  is correctly considered. The correlation coefficients between L1/L2/L5  
 258 QZSS phase signals are found to be small in Zaminpardaz et al. (2018), and are not considered  
 259 in this study.

260

261 **Table 3** Zenith-referenced standard deviations for undifferenced L5 code and phase  
 262 observations of QZSS and IRNSS satellites. Data on DOY 75 and 70, 2018 was used for the  
 263 signal analysis of the baseline CUT3-CUBB and CUCC-UWA0, respectively. Data on DOY  
 264 76 and 71, 2018 was used for multipath mitigation. We remark that after multipath mitigation,  
 265 the factor of  $\sqrt{2}$  caused by forming day-to-day differences are included in the third and fourth  
 266 columns. The QZSS standard deviations for baseline CUCC-UWA0 were taken from  
 267 Zaminpardaz et al. (2018)

	CUT3-CUBB (4 m)		CUCC-UWA0 (8 km)
	MP-uncorrected	MP-mitigated	MP-mitigated
QZSS L5 code [m]	0.16	0.11	0.08
QZSS L5 phase [m]	0.002	0.002	0.003
IRNSS L5 code [m]	0.27	0.28	0.21
IRNSS L5 phase [m]	0.002	0.001	0.003

268

269 From Table 3, for the baseline CUT3-CUBB, we see that even with the enlarged noise by  
 270 forming day-to-day differences considered in the multipath-mitigated case, the standard  
 271 deviations after multipath mitigation are similar to or smaller than those before multipath  
 272 mitigation. The QZSS L5 code signal is shown to be more precise than the IRNSS L5 code  
 273 signal.

274

## 275 **Baseline CUT3-CUBB**

276 In this section, the ambiguity resolution and RTK positioning performance of the 4 m baseline  
 277 CUT3-CUBB are analyzed assuming that the DD atmospheric delays are negligible. It is based  
 278 on single-epoch processing using all the four QZSS satellites and five IRNSS satellites (I02,  
 279 I03, I04, I05, I07) with observations available on the processing day and the subsequent day  
 280 shifted by 4 min for multipath mitigation. Time epochs with PDOP larger than 100 are excluded  
 281 from the analysis.

282

### 283 **Ambiguity resolution**

284 Making use of the variance matrix of the float ambiguities  $Q_{\hat{a}\hat{a}}$ , the ambiguity dilution of  
 285 precision (ADOP) measures the model strength for ambiguity resolution (Teunissen 1997) with

$$286 \quad \text{ADOP} = \sqrt{|Q_{\hat{a}\hat{a}}|}^{\frac{1}{m-1}} \quad (8)$$

287

288 where  $|\cdot|$  denotes the determinant of the corresponding matrix. Using the time points explained  
 289 above for the processing day DOY 77, 2018, the ADOP values are shown in Figure 7 for the  
 290 multipath-uncorrected case. The black dashed line marks the ADOP of 0.12 cycles, which as a  
 291 rule of thumb corresponds to an integer least-squares (ILS) ASR of 99.9% (Odijk and Teunissen  
 292 2008). The gaps in the red line correspond to the time points with PDOP larger than 100, which  
 293 are not used in further data analysis. We see that combining both systems is helpful to improve  
 294 the ambiguity resolution. The green line is below 0.12 cycles, which indicates an ILS ASR  
 295 higher than 99.9% in combined case. Note that the integer bootstrapping (IB) ASR that is used  
 296 in this paper lower bounds the ILS ASR (Teunissen 1999).

297

298

299 **Fig 7** L5 ADOP time series. Results are illustrated for the QZSS-standalone (red), IRNSS-  
 300 standalone (blue) and QZSS/IRNSS-combined (green) cases for the baseline CUT3-CUBB  
 301 using multipath-uncorrected observations on DOY 77, 2018. The time points used in the plot  
 302 have simultaneously observations from 4 QZSS and 5 IRNSS satellites (I02, I03, I04, I05, I07)  
 303 on DOY 77 and 78 (shifted by 4 min). The gaps in the red line represent the time points with  
 304 PDOP larger than 100. The black dashed line marks the ADOP of 0.12 cycles

305

306 Using the time points shown in Figure 7, after decorrelation of the variance-covariance  
 307 matrix of the float ambiguities, the formal integer bootstrapping (IB) ASR  $P_F$  is computed for  
 308 each epoch as (Teunissen 1999):

$$P_F = \prod_{i=1}^{m-1} \left( 2\Phi\left(\frac{1}{2\sigma_{\hat{a}_{i|I}}}\right) - 1 \right) \quad (9)$$

310

311 with

$$\Phi(x) = \int_{-\infty}^x \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{u^2}{2}\right) du \quad (10)$$

313

314 where  $\sigma_{\hat{a}_{i|I}}$  represents the conditional standard deviation of the  $i^{th}$  decorrelated ambiguity  
 315 with  $I = 1, \dots, i - 1$ . The average formal ASRs are then compared with the empirical IB  
 316 success rates  $P_E$  of the multipath-uncorrected and -mitigated cases, computed as

317

$$P_E = \frac{N_C}{N}$$

318

(11)

319 where  $N_C$  and  $N$  represent the number of epochs with correctly fixed ambiguities and the  
 320 number of all processing epochs, respectively. The reference ambiguities were obtained with  
 321 the single-epoch baseline-known model. The comparison is performed for QZSS-standalone,  
 322 IRNSS-standalone and QZSS/IRNSS-combined cases and shown in Table 4. Compared to the  
 323 standalone cases, both the formal and empirical ASRs increase from below 10% to almost  
 324 100%. The empirical and formal success rates correspond mostly well with each other, which  
 325 indicates the correspondence of the model with the data. Note that the values given in Table 4  
 326 only intends to provide an overview of the ASRs with the best satellite configurations that can  
 327 be achieved on the test day for the very short baseline in Perth, i.e., at the time points with 4  
 328 QZSS and 5 IRNSS satellites available.

329

330 **Table 4** Single-epoch empirical and average formal ASRs (see 9, 11). The results are given for  
 331 the QZSS/IRNSS-standalone and -combined cases. The same time points on DOY 77, 2018  
 332 were used as in Figure 7. Data on DOY 78 was used for multipath mitigation

	MP-uncorrected		MP-mitigated	
	Empirical	Formal	Empirical	Formal
QZSS	0.019	0.014	0.058	0.036
IRNSS	0.069	0.080	0.096	0.091
QZSS/IRNSS	0.997	1.000	0.997	1.000

333

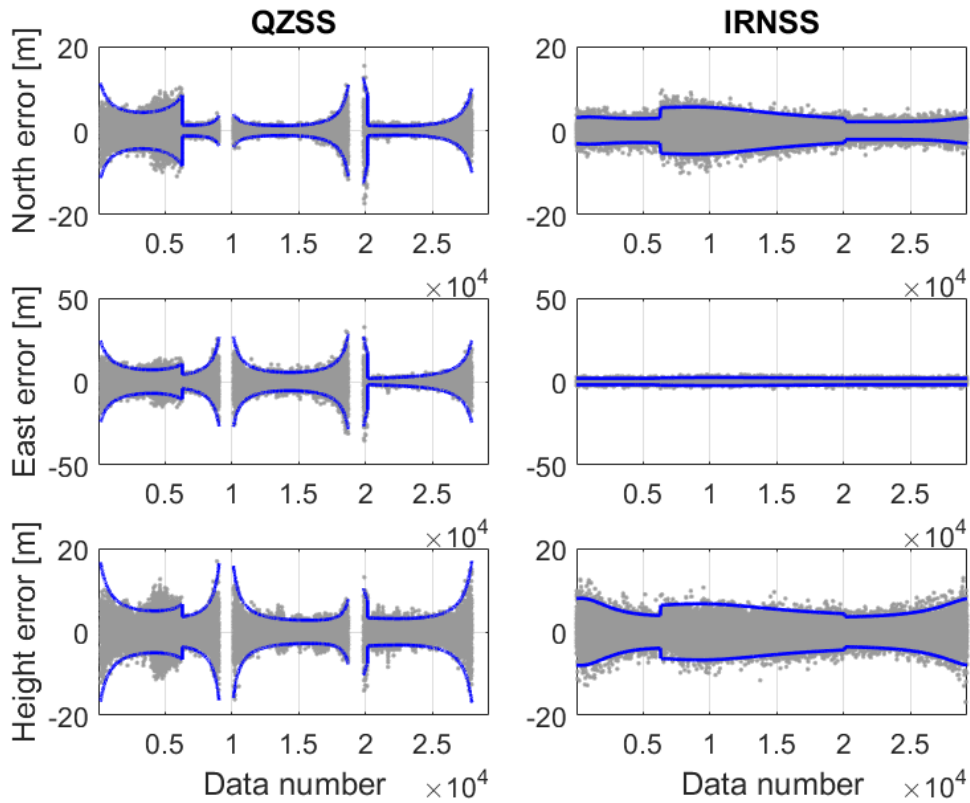

### 334 Positioning Performance

335 Making use of the L5 signals from the four QZSS satellites J01, J02, J03 and J07, as well as  
 336 the five IRNSS satellites I02, I03, I04, I05 and I07 as shown in Figure 4, the RTK positioning  
 337 performance is evaluated for the 4 m baseline CUT3-CUBB in QZSS/IRNSS standalone cases  
 338 and combined case. The time points on DOY 77, 2018 as shown in Figure 7 were used for the  
 339 data analysis. The data on DOY 78, 2018 was used for multipath mitigation.

340 Using only QZSS or IRNSS satellites, the single-epoch L5 positioning results are of poor  
 341 precision. Due to the low ASRs, as shown in Table 4, only the float north, east and height  
 342 baseline errors are plotted in Figure 8 for the multipath-mitigated case using the QZSS satellites  
 343 (left) and IRNSS satellites (right), respectively. It can be observed that the float solutions are  
 344 in the range of tens of meters. For reason of comparison, the y-axis of the east errors is scaled  
 345 to 50 meters. For IRNSS-standalone solutions, the meter-level east errors are smaller than those  
 346 in the other two directions. As explained in Zaminpardaz et al. (2018), in single-system single-  
 347 epoch case, the precision of the north, east and height baseline increments is related to the  
 348 components in  $|\sqrt{w^s}(u^s - \bar{u})|$ , with the assumption that  $w_1^s \approx w_2^s$  for the 4 m baseline and the  
 349 subscripts are thus dropped. The term  $\bar{u}$  is equal to  $\sum_{s=1}^m (w^s u^s) / \sum_{s=1}^m w^s$ . A larger component  
 350 in  $|\sqrt{w^s}(u^s - \bar{u})|$  leads to a better precision of the corresponding baseline increments. The  
 351 small east errors in IRNSS-standalone case (right panel of Figure 8) can thus be explained by  
 352 Figure 9. From Figure 8 we can also observe a poorer precision of the east baseline estimates  
 353 in QZSS-standalone case than that of the other two directions (left panel of Figure 8). This  
 354 corresponds to the results in Zaminpardaz et al. (2018) and are not explained here again.

355

356

357 **Fig 8** North, east and height baseline errors in QZSS/IRNSS-standalone case. The gray dots  
 358 represent the ambiguity-float solutions for the baseline CUT3-CUBB in QZSS-standalone [left]  
 359 and IRNSS-standalone cases [right] after multipath mitigation, and the blue lines represent the  
 360 95% formal confidence intervals of the float solutions. The same time points on DOY 77, 2018  
 361 were used as in Figure 7. Data on DOY 78, 2018 was used for multipath mitigation. The gaps  
 362 in the left panel represent the time points with PDOP larger than 100, which are not used in the  
 363 data analysis

364

365

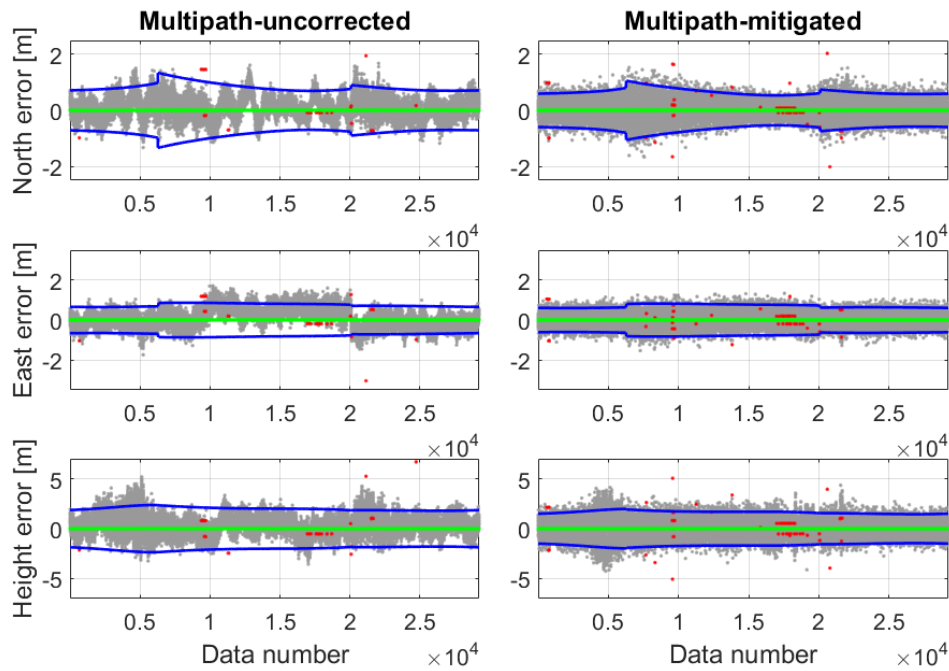

366 **Fig 9** Absolute values of the components in  $\sqrt{w^s}(u^s - \bar{u})$  for IRNSS satellites. The values are  
 367 computed for the baseline CUT3-CUBB in the IRNSS-standalone case after multipath  
 368 mitigation. The same time points on DOY 77, 2018 were used as in Figure 7

369

370 After combining both systems, the error ranges are reduced in all the three directions. Figure  
 371 10 illustrates the north, east and height errors of the same baseline in QZSS/IRNSS-combined  
 372 case. The gray, green and red dots correspond to the ambiguity-float, ambiguity-correctly-  
 373 fixed, and ambiguity-wrongly-fixed cases, and the blue line represents the 95% confidence  
 374 intervals of the float solutions. We see that the large systematic effects in the multipath-  
 375 uncorrected case are reduced after multipath mitigation. This is directly reflected in the reduced

376 mean values in the absolute sense as shown in Table 5. We remark that in Table 5 only the time  
 377 points with correctly fixed ambiguities were used to calculate the mean values in ambiguity-  
 378 fixed case. The ambiguity-fixed mean values are not given for the standalone cases since they  
 379 are not considered representative with the low ASRs shown in Table 5. After multipath  
 380 mitigation, the percentage of float solutions (gray dots) within the 95% formal confidence  
 381 intervals (blue lines) is around 96.3%, 95.6% and 93.1% in the north, east and up directions,  
 382 respectively. This shows the correspondence between the formal and empirical solutions.

383

384

385 **Fig 10** North, east and height baseline errors in QZSS/IRNSS-combined case. The gray, green  
 386 and red dots represent the ambiguity-float, ambiguity-correctly-fixed and ambiguity-wrongly-  
 387 fixed solutions, respectively, before [left] and after multipath mitigation [right] for baseline  
 388 CUT3-CUBB. The blue lines represent the 95% formal confidence intervals of the float  
 389 solutions. The processing is based on QZSS/IRNSS-combined L5 observations with the same  
 390 time points on DOY 77, 2018 used as in Figure 7. Data on DOY 78, 2018 was used for multipath  
 391 mitigation

392

393 **Table 5** Mean of the single-epoch positioning errors. The results are given in the format of the  
 394 QZSS-standalone/IRNSS-standalone/QZSS-IRNSS-combined cases. The same time points on

395 DOY 77, 2018 were used as in Figure 7. Data on DOY 78, 2018 was used for multipath  
 396 mitigation

Direction	Ambiguity float [m]		Ambiguity-fixed [m]	
	MP-uncorrected	MP-mitigated	MP-uncorrected	MP-mitigated
North	0.07/-0.44/0.09	-0.03/-0.09/0.03	--/--/-0.001	--/--/-0.000
East	-0.33/0.36/0.11	-0.17/0.10/0.02	--/--/0.003	--/--/0.000
Height	0.66/-0.73/0.34	-0.00/-0.11/0.06	--/--/0.000	--/--/0.000

397

398 The empirical and average formal standard deviations of the north, east and height errors are  
 399 shown in Table 6 in multipath-uncorrected and -mitigated cases. We remark that only the time  
 400 points with correctly-fixed ambiguities were used for computing the standard deviations in  
 401 ambiguity-fixed case, and the average formal standard deviations are calculated as the square  
 402 roots of the mean formal variances. Due to the low ASRs in QZSS/IRNSS-standalone cases  
 403 (Table 5), their standard deviations in the ambiguity-fixed case are not considered  
 404 representative and are not give in the table. Using QZSS/IRNSS-combined observations, the  
 405 standard deviations are within decimeters and millimeters in ambiguity-float and -fixed cases,  
 406 respectively. In ambiguity-float case, the standard deviations are reduced from meters in  
 407 standalone cases to decimeters in QZSS/IRNSS-combined case. Note the correspondence  
 408 between the empirical and formal results.

409

410 **Table 6** Empirical and average formal standard deviations of the single-epoch positioning  
 411 errors. The results are presented for the baseline CUT3-CUBB with the formal results given in  
 412 brackets. The same time points on DOY 77, 2018 were used as in Figure 7. Data on DOY 78,  
 413 2018 was used for multipath mitigation

System	Direction	Ambiguity float [m]		Ambiguity-fixed [m]	
		MP-uncorrected	MP-mitigated	MP-uncorrected	MP-mitigated
QZSS	North	2.35(2.67)	1.76(1.93)	--	--

	East	5.47(6.79)	4.18(4.90)	--	--
	Height	4.09(4.13)	2.68(2.98)	--	--
IRNSS	North	2.12(1.88)	1.85(1.89)	--	--
	East	1.41(1.07)	1.07(1.08)	--	--
	Height	2.83(2.85)	2.60(2.86)	--	--
QZSS/IRNSS	North	0.37(0.43)	0.32(0.34)	0.003(0.004)	0.003(0.004)
	East	0.48(0.39)	0.35(0.36)	0.002(0.003)	0.003(0.003)
	Height	0.98(1.02)	0.93(0.84)	0.007(0.008)	0.006(0.008)

414

415 To have an overview of the GPS-related single-epoch RTK performance in Perth, in Table  
416 7 we also give the daily mean formal ASRs and formal standard deviations of the positioning  
417 errors in L5 single-, dual- and triple-system cases for baseline CUT3-CUBB. The satellite  
418 configurations on DOY 77, 2018, the ground truth of the baselines, and the multipath-mitigated  
419 standard deviations given in Table 3 were used for the processing. The GPS L5 code and phase  
420 multipath-mitigated standard deviations were taken from Zaminpardaz et al. (2017), and the  
421 sampling rate is 1 Hz. All time epochs with not less than 4 satellites above the elevation mask  
422 and with PDOP smaller than 100 were used for the processing. The percentage of these epochs  
423 within one day is denoted by  $p_{s \geq 4}$ . Note that the results shown in Table 7 is purely based on  
424 geometry and is not related to any real observations. Only the time points with ASR larger than  
425 99.9% were used for computing the ambiguity-fixed standard deviations. As shown in the  
426 second column of Table 7, the number of the time points that was taken into account for  
427 calculating the mean ASRs and standard deviations are different for different system  
428 combinations. The mean formal ASR of about 0.285 in GPS-standalone case, e.g., was  
429 computed based on about 44% of the time points in the test day. In other time points, the  
430 number of the available GPS IIF satellites is mostly lower than that of the IRNSS satellites,  
431 which results in a lower mean formal ASR in QZSS/GPS-combined case than that in  
432 QZSS/IRNSS-combined case. Within several hours, only one or two GPS IIF satellites are  
433 above the elevation mask. This results in low ASRs in e.g. IRNSS/GPS-combined case during  
434 these time periods, and slightly lower mean formal ASRs in IRNSS/GPS-combined case than  
435 that in QZSS/IRNSS-combined case.

436

437 **Table 7** Daily **average** mean formal RTK solutions for the baseline CUT3-CUBB. All time  
 438 epochs on DOY 77, 2018 with not less than 4 satellites above the elevation mask and with  
 439 PDOP smaller than 100 were used for processing. The terms  $p_{s \geq 4}$  and  $\bar{P}_F$  denote the percentage  
 440 of these epochs within the test day and the mean formal ASR, respectively. The analysis was  
 441 performed using multipath-mitigated signal standard deviations. Note that the ambiguity-fixed  
 442 standard deviations are computed only based on the time epochs with ASR larger than 99.9%.  
 443 **The GPS IIF satellites sending L5 signals were used for computation of the GPS-related cases.**

System	$p_{s \geq 4}$	$\bar{P}_F$	Ambiguity-float [m]			Ambiguity-fixed [m]		
			North	East	Height	North	East	Height
QZSS	43%	0.032	1.74	4.78	2.82	--	--	--
IRNSS	97%	0.056	4.57	1.66	6.39	--	--	--
GPS	44%	0.285	0.96	0.43	1.22	--	--	--
QZSS/IRNSS	100%	0.995	0.54	0.40	1.06	0.005	0.003	0.009
QZSS/GPS	100%	0.871	0.28	0.56	0.75	0.003	0.003	0.007
IRNSS/GPS	100%	0.966	0.35	0.43	1.01	0.002	0.003	0.006
QZSS/IRNSS/GPS	100%	1.000	0.20	0.23	0.54	0.002	0.002	0.006

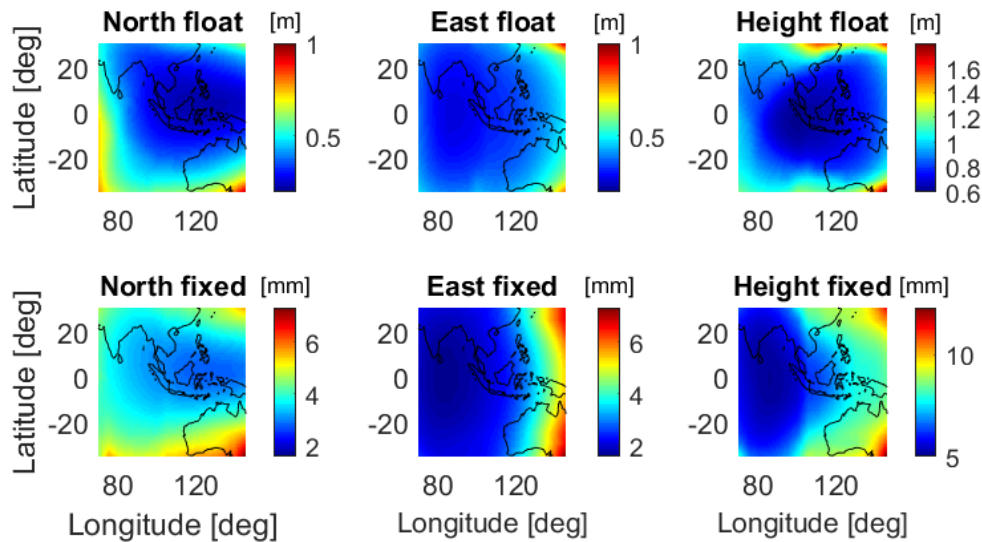

444

445 From Table 7 it can be observed that low daily mean ASRs of single-epoch L5  
 446 QZSS/IRNSS/GPS-standalone solutions increase to above 85% after using combined  
 447 observations from any two systems. Among them, the QZSS/IRNSS, IRNSS/GPS and  
 448 QZSS/IRNSS/GPS-combined solutions have reached a daily mean ASR of above 95%.  
 449 Millimeter-level ambiguity-fixed **standard deviations** can be obtained for the combined cases  
 450 using time epochs with ASRs larger than 99.9%.

451 Apart from for the 4 m baseline in Perth, we also computed the daily **average** mean formal  
 452 standard deviations of the north, east and height errors for short baselines located in a larger  
 453 area, including part of the QZSS and IRNSS service areas. The results are processed in the  
 454 QZSS/IRNSS-combined case using multipath-mitigated signal standard deviations. The  
 455 reference stations are assumed to be located at the grid points from 35°S to 30°N with a step

456 of 5° in latitude and from 70°E to 145°E with a step of 5° in longitude. All time points on DOY  
 457 77, 2018 with at least 4 satellite above the elevation mask and with PDOP smaller than 100  
 458 were used for the analysis. Only the time epochs with the ASR larger than 99.9% were used to  
 459 compute the ambiguity-fixed solutions. The grid values are smoothed in Figure 11 for  
 460 visualization purpose. As shown in the figure, in the north-west of Australia, the average formal  
 461 standard deviations of the positioning errors amount to about 4 and 8 dm in the horizontal  
 462 (north and east) and vertical directions, respectively, in ambiguity-float case. In ambiguity-  
 463 fixed case, the average formal standard deviations are about 3-4 mm and 8 mm in the horizontal  
 464 and vertical directions, respectively. In India, the averaged ambiguity-float standard deviations  
 465 amount to about 3-4 dm and 9 dm in the horizontal and vertical directions, and those in  
 466 ambiguity-fixed case amount to about 2-4 mm and 5 mm in horizontal and vertical directions,  
 467 respectively. In Japan, which is not shown in Figure 11, the values in ambiguity-float case  
 468 increase to about 1 and 2 m in the horizontal and vertical directions, and the ambiguity-fixed  
 469 values are about 5-6 mm and 1 cm in the horizontal and vertical directions.

470

471

472 **Fig 11** Average formal standard deviations of the baseline errors. The processing was  
 473 performed for L5 QZSS/IRNSS-combined case on DOY 77, 2018 using multipath-mitigated  
 474 signal standard deviations (Table 3). The epochs with less than 4 satellites or with PDOP larger  
 475 than 100 were excluded from the analysis

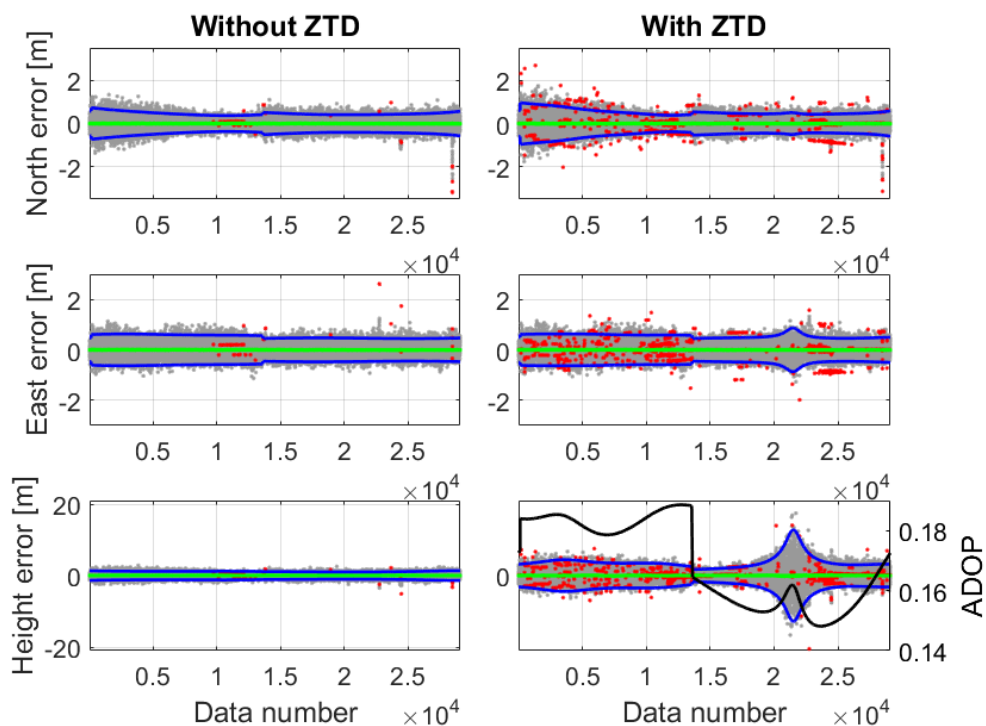

476

477 **Baseline CUCC-UWA0**

478 For the 8 km baseline CUCC-UWA0, multipath-mitigated solutions without and with the  
 479 estimation of the between-receiver ZTDs are presented for DOY 103, 2018. The data on DOY  
 480 104, 2018 was used for multipath mitigation. Like with the short baseline CUT3-CUBB, only  
 481 the time epochs with observations from 4 QZSS and 5 IRNSS satellites (I02, I03, I04, I05, I07)  
 482 were used for the processing. The results are shown and discussed in the QZSS/IRNSS-  
 483 combined case. Note that the processing time that we use does not show large DD ionospheric  
 484 delays.

485 Figure 12 illustrates the north, east and height baseline errors of the single-epoch solutions  
 486 without and with the estimation of the between-receiver ZTDs. It can be observed that  
 487 estimating the between-receiver ZTDs leads to increasing errors mainly in the vertical  
 488 direction. This is caused by the high correlation between the ZTDs and the kinematic height  
 489 estimates (Rothacher and Beutler 1998). In the right panel of Figure 12, more wrongly-fixed  
 490 ambiguities can be observed in the first half of the processing time. This corresponds to the  
 491 higher ADOPs during this time span, which are illustrated with the black line.

492

493

494 **Fig 12** Single-epoch north, east and height errors of the baseline CUCC-UWA0. The gray,  
 495 green and red dots represent the ambiguity-float, ambiguity-correctly-fixed and ambiguity-  
 496 wrongly-fixed solutions, respectively, without [left] and with the estimation of the between-

497 receiver ZTDs [right]. The black line illustrates the ADOPs with the between-receiver ZTDs  
 498 estimated, and the blue lines represent the 95% formal confidence intervals of the float  
 499 solutions. The processing is based on multipath-mitigated QZSS/IRNSS-combined L5  
 500 observations at the time points with observations available from 4 QZSS and 5 IRNSS (I02,  
 501 I03, I04, I05, I07) on DOY 103 and 104 (shifted by 4 min for multipath mitigation), 2018  
 502

503 From Figure 12, between  $2 \cdot 10^4$  and  $2.3 \cdot 10^4$  s, increasing height errors can be observed  
 504 when the between-receiver ZTDs are estimated. Extended from Zaminpardaz et al. (2018), for  
 505 the single-epoch multi-system case, the baseline variance-covariance matrix with the  
 506 estimation of the between-receiver ZTDs can be formulated as:

$$507 \quad Q_{\hat{x}\hat{x}} = \begin{pmatrix} Q_{\hat{c}\hat{c}} & Q_{\hat{c}\hat{\tau}} \\ Q_{\hat{c}\hat{\tau}}^T & Q_{\hat{\tau}\hat{\tau}} \end{pmatrix} = \begin{pmatrix} N_{\hat{c}\hat{c}} & N_{\hat{c}\hat{\tau}} \\ N_{\hat{c}\hat{\tau}}^T & N_{\hat{\tau}\hat{\tau}} \end{pmatrix}^{-1} = \left( \sum_{s=1}^m q^s (\beta^s - \bar{\beta})(\beta^s - \bar{\beta})^T \right)^{-1}$$

508 (12)

509 with

$$510 \quad q^s = (\sigma_p^s)^{-2} ((w_1^s)^{-1} + (w_2^s)^{-1})^{-1}$$

511 (13)

512

$$513 \quad \bar{\beta} = \frac{\sum_{s=1}^m (q^s \beta^s)}{\sum_{s=1}^m q^s}$$

514 (14)

515 where  $\sigma_p^s$  represents the zenith-referenced L5 code standard deviations of the corresponding  
 516 system for satellite  $s$ . The subscript  $c$  and  $\tau$  corresponds to the baseline elements and the  
 517 between-receiver ZTDs, respectively. The vector  $\beta^s$  is equal to  $[(u^s)^T, g^s]^T$ . The baseline  
 518 variance-covariance matrix  $Q_{\hat{c}\hat{c}}$  in this case can be formulated as:

$$519 \quad Q_{\hat{c}\hat{c}} = N_{\hat{c}\hat{c}}^{-1} + \Delta Q$$

520 (16)

521 with

$$522 \quad \Delta Q = N_{\hat{c}\hat{c}}^{-1} N_{\hat{c}\hat{\tau}} q N_{\hat{c}\hat{\tau}}^T N_{\hat{c}\hat{c}}^{-1}$$

523 (17)

524 
$$q = (N_{\hat{\tau}\hat{\tau}} - N_{\hat{\tau}\hat{c}}^T N_{\hat{c}\hat{c}}^{-1} N_{\hat{c}\hat{\tau}})^{-1}$$

525 (18)

526 where  $N_{\hat{c}\hat{c}}^{-1}$  corresponds to the baseline variance-covariance matrix without estimation of the  
527 between-receiver ZTDs, and the term  $(N_{\hat{\tau}\hat{\tau}} - N_{\hat{\tau}\hat{c}}^T N_{\hat{c}\hat{c}}^{-1} N_{\hat{c}\hat{\tau}})^{-1}$  is a scale that changes with the  
528 time, denoted by  $q$ . To explain the baseline precision differences without and with the  
529 estimation of the between-receiver ZTDs, the values of  $\sqrt{q}$  and  $\sqrt{\text{diag}(\Delta Q)}$  (see 17) for the  
530 north, east and height components are shown in Figure 13. The change of  $\sqrt{q}$  almost only  
531 influences the height component of  $\sqrt{\text{diag}(\Delta Q)}$ , and the pattern corresponds to the change in  
532 the height errors, as shown in the right bottom panel of Figure 12.

533

534

535 **Fig 13** Values of  $\sqrt{q}$  [top] and  $\sqrt{\text{diag}(\Delta Q)}$  [bottom] (Eq. 16). The day pair DOY 103/104 were  
536 used for computing the values in multipath-mitigated case

537

538 The empirical and formal standard deviations of the baseline errors and the ASRs are listed  
539 in Tables 8 and 9. Both the empirical and formal ASRs decrease by about 15% when the  
540 between-receiver ZTDs are estimated. With the ambiguities correctly fixed, standard  
541 deviations at mm- and cm-level can be obtained in the horizontal and vertical directions,  
542 respectively (Table 8). The ASRs are above 99% without the estimation of the between-  
543 receiver ZTDs.

544

545 **Table 8** Empirical and average formal standard deviations of the single-epoch baseline errors.  
 546 The results are presented for the baseline CUCC-UWA0 with the formal results contained in  
 547 brackets. The same time points on DOY 103, 2018 were used as in Figure 12. Data on DOY  
 548 104, 2018 was used for multipath mitigation

System	Direction	Ambiguity float [m]		Ambiguity-fixed [m]	
		Without ZTD	With ZTD	Without ZTD	With ZTD
QZSS/IRNSS	North	0.27 (0.24)	0.30(0.28)	0.006 (0.007)	0.006(0.007)
	East	0.26 (0.27)	0.28(0.29)	0.005 (0.005)	0.005(0.006)
	Height	0.63 (0.59)	1.93(2.21)	0.013 (0.015)	0.034(0.048)

549

550 **Table 9** Single-epoch empirical and average formal ASRs (cf. 9, 11). The same time points on  
 551 DOY 103, 2018 were used as in Figure 12. Data on DOY 104, 2018 was used for multipath  
 552 mitigation

	Empirical ASR	Formal ASR
Without ZTD	0.995	0.991
With ZTD	0.847	0.829

553

554 For the 8 km baseline CUCC-UWA0, multi-epoch solutions were also computed using the  
 555 same time epochs as in Figure 12, i.e., the time points observing 4 QZSS and 5 IRNSS satellites.  
 556 The ambiguities were assumed to be constant. The starting time of the processing was shifted  
 557 by 1 epoch for each round of the processing. Only processing intervals with continuous time  
 558 epochs were used for the calculation. To reduce the influences of the remaining multipath on  
 559 the dynamic model, the elevation mask was increased to 15 degrees. The empirical and average  
 560 formal ASRs of all processing rounds are listed in Table 10 for  $t$  of 2, 6 and 10 s. Without

561 estimating the between-receiver ZTDs, the empirical and average formal ASRs already reach  
 562 about 100% in 2 s. With the between-receiver ZTDs estimated, after 10 s, the empirical and  
 563 average formal ASRs are about 99% and 100%, respectively. In our tested case, the scenario  
 564 without estimating ZTDs shows better ambiguity resolution performance in both single- and  
 565 multi-epoch cases. However, we remark that this may not necessarily apply for environments  
 566 or time periods with strong DD ZTDs.

567

568 **Table 10** Multi-epoch empirical and average formal mean ASRs for baseline CUCC-UWA0  
 569 without and with the estimation of the between-receiver ZTDs. The same time points on DOY  
 570 103, 2018 were used as in Figure 12. Data on DOY 104, 2018 was used for multipath mitigation

	Empirical ASR			Formal ASR		
	2 s	6 s	10 s	2 s	6 s	10 s

With ZTD	0.975	0.988	0.990	0.989	1.000	1.000

571

## 572 Conclusions

573 Taking advantage of the location of Australia, we evaluated the L5 single-epoch RTK  
 574 performance from the two regional navigation satellite systems, QZSS and IRNSS. Using 1 Hz  
 575 L5-data simultaneously observed from 4 QZSS satellites and 5 IRNSS satellites (I02, I03, I04,  
 576 I05, I07) above the elevation mask of 10 degrees, for a very short baseline of 4 m, the  
 577 QZSS/IRNSS-combined results were compared with the QZSS- and IRNSS-standalone  
 578 solutions. In addition to that, the QZSS/IRNSS-combined results were also evaluated for an 8  
 579 km baseline without and with the between-receiver ZTDs considered in the observation model.

580 For the 4 m baseline, the single-epoch results show that the ASRs were significantly  
 581 improved after combining both systems, i.e., from below 10% in standalone cases to almost  
 582 100% in the combined case. The standard deviations of the ambiguity-float positioning errors  
 583 are reduced from meters to decimeters due to the much better geometry provided by both  
 584 systems. After fixing the ambiguities, millimeter-level standard deviations can be obtained  
 585 when using QZSS/IRNSS-combined observations. For this 4 m baseline in Perth, a formal

586 analysis was also performed for the entire day with the GPS Block IIF satellites considered. It  
587 was found that the daily mean ASRs are below 30% for single-epoch single-system solutions  
588 using L5 signals. Combining any two systems of QZSS, IRNSS and GPS, or combining all  
589 three systems, lead to daily mean ASRs above 85% and millimeter-level positioning precision  
590 in ambiguity-fixed case. Based on the formal analysis performed for the short-baseline  
591 QZSS/IRNSS-combined solutions in a larger area, average formal standard deviations of the  
592 ambiguity-fixed positioning errors amount to about 3-4 and 8 mm in the horizontal and vertical  
593 directions, respectively, in the north-west of Australia.

594 For the 8 km baseline, the single-epoch solutions were processed in multipath-mitigated  
595 QZSS/IRNSS-combined case. We notice that estimating the between-receiver ZTDs increases  
596 the height errors due to the high correlation between the ZTDs and the height estimates. In  
597 general, without large DD ionospheric delays observed in the processing time, standard  
598 deviations of the ambiguity-fixed positioning errors can be obtained at millimeter- and  
599 centimeter-level in horizontal and vertical directions, respectively. For single-epoch solutions,  
600 the ASRs are above 80% and 99% with and without the estimation of the between-receiver  
601 ZTDs, respectively. For multi-epoch solutions with a higher elevation mask of 15 degrees, at a  
602 processing time of 10 s, the empirical ASRs are about 99% and 100%, respectively, with and  
603 without the estimation of the between-receiver ZTDs.

604

## 605 **Acknowledgments**

606 We would like to thank Septentrio for providing the receiver at station UWA0 and Dr. Sascha  
607 Schediwy from the University of Western Australia for hosting this station. Thanks are also  
608 given to IGS MGEX and CDDIS for providing the combined broadcast ephemeris on the  
609 server. Peter J.G. Teunissen is the recipient of an Australian Research Council (ARC)  
610 Federation Fellowship (Project Number FF0883188). The work of Pei Chen is funded in part  
611 by Ministry of Science and Technology of China through cooperative agreement No.  
612 2014CB845303.

### 693 **Author Biographies**

694

695 **Kan Wang** is a research associate in the GNSS Research Centre, Curtin University. She  
696 received her PhD in GNSS advanced modeling from ETH Zurich in 2016, and is working on  
697 satellite clock modeling, multi-frequency and multi-GNSS ambiguity resolution and PPP-RTK  
698 processing.

699 **Pei Chen** received his Ph.D. degree in aerospace engineering from Beihang University,  
700 Beijing, in 2007. He is currently an associate professor at the School of Astronautics, Beihang  
701 University. His current research activities comprise spacecraft navigation, GNSS application,  
702 and orbit determination.

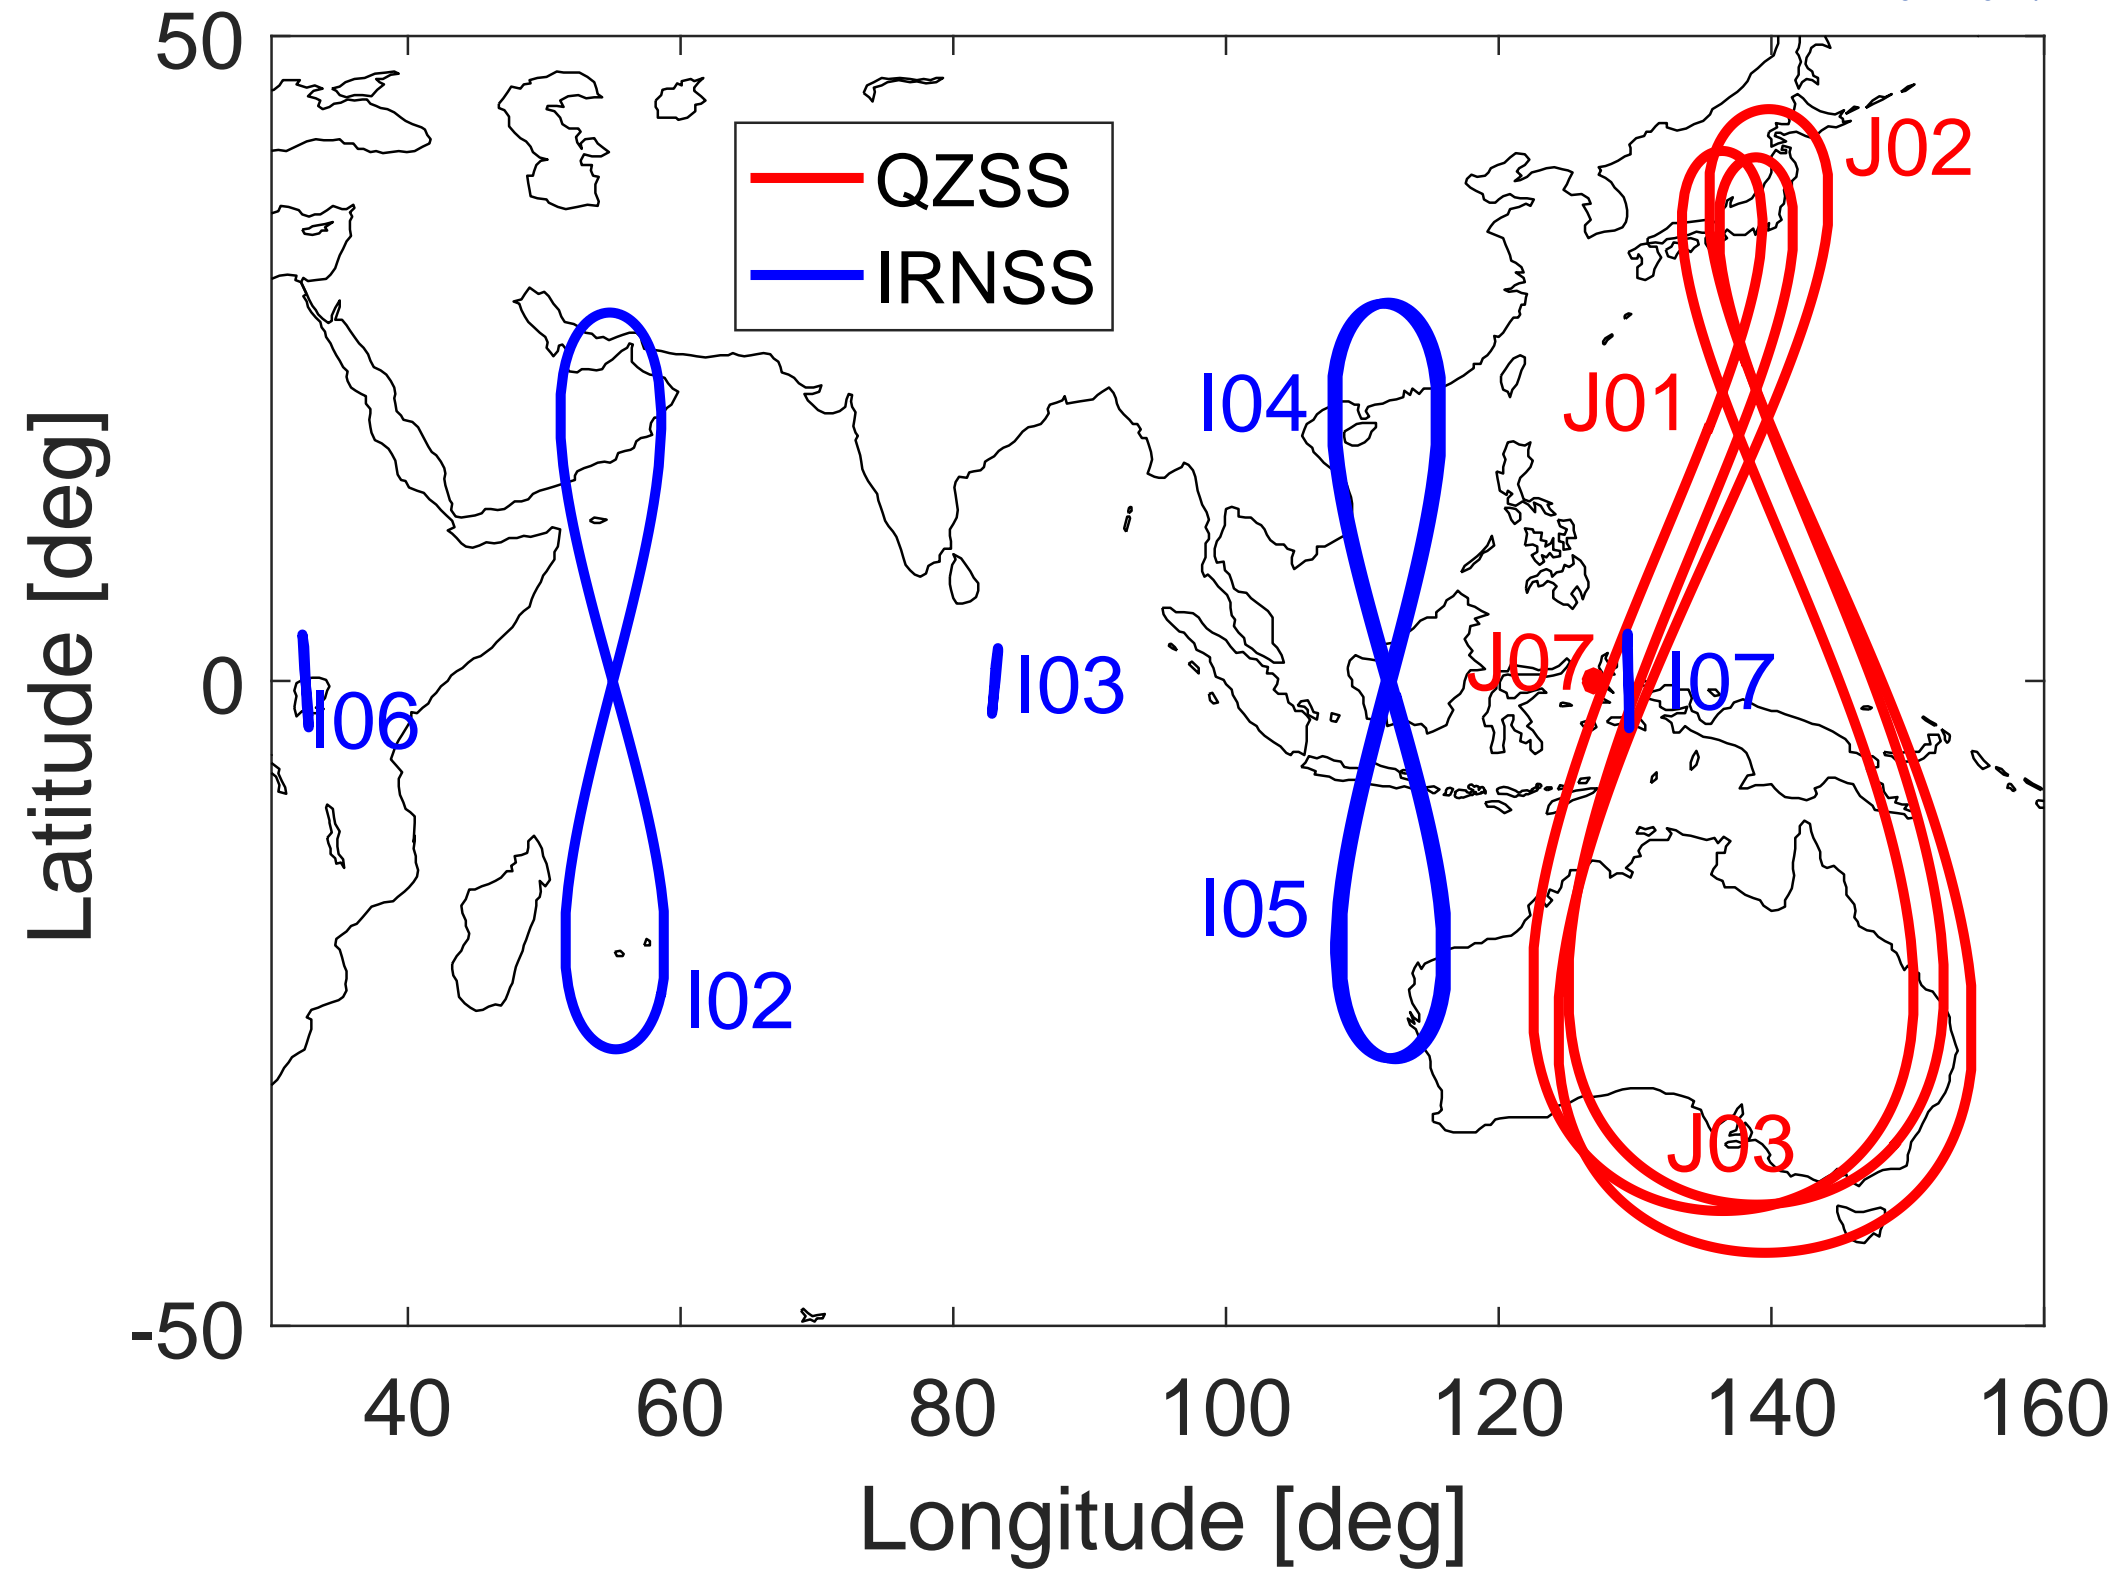

703 **Safoora Zaminpardaz** received her Ph.D. in Geodesy and GNSS from Curtin University in  
704 2018. She is now working as a Researcher at Delft University of Technology (TU Delft). Her  
705 research interests include array-based multi-GNSS positioning, integrity monitoring and  
706 ionosphere sensing.

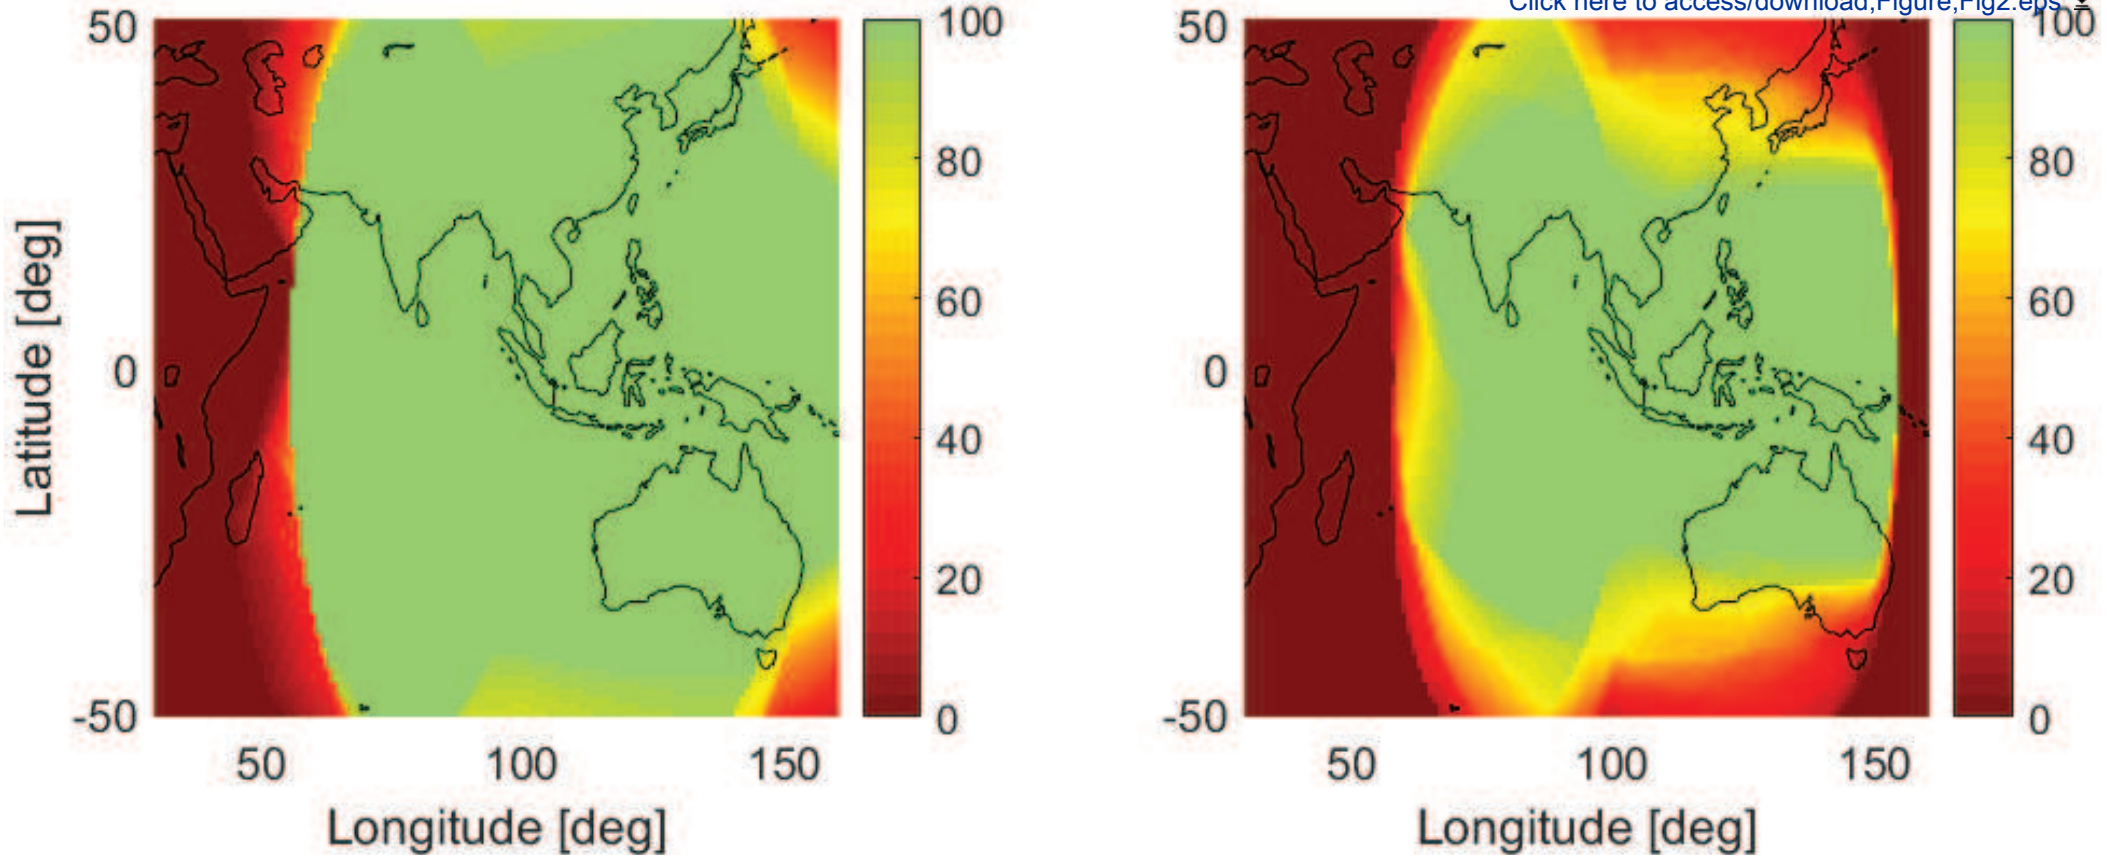

707 **Peter J.G. Teunissen** is Professor of Geodesy and Navigation at the Delft University of  
708 Technology, Delft, The Netherlands, and Curtin University, Perth, Australia. He is the recipient  
709 of an Australian Research Council (ARC) Federation Fellowship (project number FF0883188).  
710 His current research interests are multi-GNSS and multi-frequency precise positioning,  
711 navigation and timing applications.
