# Improved Roach-based Algorithms for Global Optimization Problems 

# Obagbuwa Ibidun Christiana 

211559859

A thesis submitted in the fulfilment of the requirements for the Degree of Doctor of Philosophy in Computer Science

In the

School of Mathematics, Statistics, and Computer Science
University of KwaZulu- Natal
Durban, South Africa
November 2014

# UNIVERSITY OF KWAZULU-NATAL COLLEGE OF AGRICULTURE, ENGINEERING AND SCIENCE 

## DECLARATION

The research described in this thesis was performed at the University of KwaZulu-Natal under the supervision of Dr. Adewumi A.O. I hereby declare that all the materials incorporated in this thesis are my own original work except where acknowledgement is made by name or in the form of reference. The work contained herein has not been submitted in part or whole for a degree at any university.

Signed:

Date:

As candidate's supervisor, I have approved the dissertation for submission

## DECLARATION PLAGIARISM

I, Obagbuwa Ibidun Christiana declare that

1. The research reported in this thesis, except where otherwise indicated, is my original research.
2. This thesis has not been submitted for any degree or examination at any other University.
3. This thesis does not contain other persons data, pictures, graphs or other information, unless specifically acknowledged as being sourced from other persons.
4. This thesis does not contain other persons writing, unless specifically acknowledged as being sourced from other researchers. Where other written sources have been quoted, then:
a. Their words have been re-written and the general information attributed to them has been referenced
b. Where their exact words have been used, then their writing has been placed in italics and inside quotation marks, and referenced.
5. This thesis does not contain text, graphics or Tables copied and pasted from the Internet, unless specifically acknowledged, and the source being detailed in the thesis and in the References section.

Signed:

Student name: Obagbuwa Ibidun Christiana

## Dedication

This work is dedicated to the ALMIGHTY GOD, the 'I AM THAT I AM' who is my all in all. May his name be praised forever and ever.

## Abstract

Optimization of systems plays an important role in various fields including mathematics, economics, engineering and life sciences. A lot of real world optimization problems exist across field of endeavours such as engineering design, space planning, networking, data analysis, logistic management, financial planning, risk management, and a host of others. These problems are constantly increasing in size and complexity, necessitating the need for improved techniques.

Many conventional approaches have failed to solve complex problems effectively due to increasingly large solution space. This has led to the development of evolutionary algorithms that draw inspiration from the process of natural evolution. It is believed that nature provides inspirations that can lead to innovative models or techniques for solving complex optimization problems. Among the class of paradigm based on this inspiration is Swarm Intelligence (SI).

SI is one of the recent developments of evolutionary computation. A SI paradigm is comprised of algorithms inspired by the social behaviour of animals and insects. SI-based algorithms have attracted interest, gained popularity and attention because of their flexibility and versatility. SIbased algorithms have been found to be efficient in solving real world optimization problems. Examples of SI algorithms include Ant Colony Optimization (ACO) inspired by the pheromone trail-following behaviour of ant species; Particle Swarm Optimization (PSO) inspired by flocking and swarming behaviour of insects and animals; and Bee Colony Optimization (BCO) inspired by bees' food foraging.

Recent emerging techniques in SI includes Roach-based Algorithms (RBA) motivated by cockroaches social behaviour. Two recently introduced RBA algorithms are Roach Infestation Optimization (RIO) and Cockroach Swarm Optimization (CSO) which have been applied to some optimization problems to achieve competitive results when compared to PSO. This study is motivated by the promising results of RBA, which have shown that the algorithms have potentials to be efficient tools for solving optimization problems. Extensive studies of existing RBA were carried out in this work revealing the shortcomings such as slow convergence and entrapment in local minima. The aim of this study is to overcome the identified drawbacks. We investigate RBA variants that are introduced in this work by introducing parameters such as constriction factor and sigmoid function that have proved effective for similar evolutionary algorithms in the literature.

In addition components such as vigilance, cannibalism and hunger are incorporated into existing RBAs. These components are constructed by the use of some known techniques such as simple Euler, partial differential equation, crossover and mutation methods to speed up convergence and enhance the stability, exploitation and exploration of RBA.

Specifically, a stochastic constriction factor was introduced to the existing CSO algorithm to improve its performance and enhance its ability to solve optimization problems involving thousands of variables. A CSO algorithm that was originally designed with three components namely chase-swarming, dispersion and ruthlessness is extended in this work with hunger component to improve its searching ability and diversity. Also, predator-prey evolution using crossover and mutation techniques were introduced into the CSO algorithm to create an adaptive search in each iteration thereby making the algorithm more efficient. In creating a discrete version of a CSO algorithm that can be used to evaluate optimization problems with any discrete range value, we introduced the sigmoid function.

Furthermore, a dynamic step-size adaptation with simple Euler method was introduced to the existing RIO algorithm enhancing swarm stability and improving local and global searching abilities. The existing RIO model was also re-designed with the inclusion of vigilance and cannibalism components.

The improved RBA were tested on established global optimization benchmark problems and results obtained compared with those from the literature. The improved RBA introduced in this work show better improvements over existing ones.

## Acknowledgements

Firstly, my acknowledgement goes to the ALMIGHTY GOD, whose presence is with me always. All through the period of this work, I saw HIS finger, HIS hand and HIS being. This work is a proof of the strange works and acts of GOD. GOD the FATHER, GOD the SON and GOD the HOLY SPIRIT are very real; the WORD of GOD is true and is the TRUTH (John 17:17). All inspirations and ideas came from HIM via the Spirit of Truth (1 Corri 2: 9-10). Every challenge encountered during this work gave way for the TRUTH, the TRUTH prevailed in all situation and circumstance. All GLORY about and around this work is ascribed unto the ALMIGHTY GOD.

Also, I acknowledge all the effort of my supervisor, Dr. A.O Adewumi. He has been there for me from inception, beginning from my journey from my country to South Africa. He assisted me in securing an accommodation and ensure that I properly settled down. From the beginning of this work till the end, I enjoyed his guidance. Thank you very much sir. May the good LORD rewards you.

My acknowledgement also goes to my colleagues (Post Doctoral Fellows at the time of study): Dr. Sawyerr Babatunde of University of Lagos; Dr. Nachamada Blamah of University of Jos and Dr. Adebiyi Ayodele of Covenant University Nigeria; I appreciate your encouragement. I equally appreciate my other colleagues in my research group: Ajibola Sunday, Luke Joel, Olusanya Micheal, Matins Arasomwan, Stephen Akandwanaho and Ameline. Also to every staff of school of Mathematics, Statistics and Computer Science, University of KwaZulu-Natal, appreciation is given for their kindness.

I am grateful to my employer, Lagos State University, Lagos, Nigeria, for granting me a training leave for this doctoral degree. Also acknowledgement is given to every staff and students of the Department of Computer Sciences, Lagos State University.

I acknowledge my dear father, Dr. Olaniyi David Oyedepo, the presiding Bishop of Living Faith Church Worldwide (aka Winners Chapel International), God has used him greatly to transform my life through the liberation mandate and the preaching of the word of faith. I am able to go this far and still flying higher by the impacts of the liberation messages. Also to Winners family worldwide, acknowledgement is given for sweet fellowship.

Acknowledgement is rendered to Joseph kirk and Jonas Lundgren for making their codes ac-
cessible in Mathworks, which became an inspiration for our study in travelling salesman problems.
Furthermore, my appreciation goes to my sweet family and precious home: To my husband, Mr. Obagbuwa Oloyede (ACA), whom GOD has used to make this programme a reality. I thank him for the rare privilege given to me to be away from home for this long period of time, he gave me the permission to go and promised to take good care of our children which he did beyond expectation. You are the best husband and father in the whole world, you are so kind and committed to the course and advancement of your home and that of every member of the family. You told me that you can do anything to take me to the peak of my carrier and you stand by it. May God Almighty continue to bless you and give unto you long life to eat the fruit of your labor (Isa 65:2024). And to the wonderful heritage of GOD in my home that I am privileged by God to mother: Oluwadamilola, Oluwatimilehin and Oluwagbemiga, who are outstanding blessings from GOD. I appreciate your true love, patience, understanding and prayer for me. In my lifetime you shall sit on great thrones in the name of Jesus Christ our Savior (AMEN). Also to my late father, HRH Falope Francis Fagite, my mother Mrs. Elizabeth Falope and to all my Siblings, due acknowledgements are rendered.

## Chapter 1

## Introduction

### 1.1 Background

Optimization is the search for the best possible solution among diverse solutions to a given problem [1, 2, 3, 4]. The task of finding the solutions that are as good as possible and widely different from each other is referred to as global optimization [2]. Optimization is useful across disciplines for example: airline companies schedule crews and aircraft to minimize cost; business investors make selections that avoid excessive risks, while desiring high return rates; manufacturers strive to maximize efficiency in the design and operation of their production processes; the economist and operational researchers desire optimal allocation of resources in industrial and social settings, and so on.

A lot of real-world and theoretical problems can be modelled as a general framework to maximize or minimize a mathematical function of variables, subject to some constraints. Usually, the terms maximization or minimization is used to represent the term optimization; maximization of the function $f$ is equivalent to minimising $-f$. The mathematical function that is to be optimized is known as the objective function, which normally contain a number of variables [1]. Optimization processes involve the construction of relevant models, by expressing optimization problem in mathematical terms and identifying the objective, the variables and the constraints of the problem [1, 4].
a. An objective is the performance quantitative measure of the system that needs to be minimized or maximized. The objective must be identified first, for example to maximize profits or minimize the cost of production. The objective function represents the goal/objective of the problem in terms of decision variables.
b. The variables or the unknowns are the system components for which we want to find values. For example, the variables can be the amount of each resource consumed or the time spent
on each activity.
c. The constraints are the functions that describe the relationships among the variables and also define the allowable values for the variables. For example, the amount of a resource consumed cannot exceed the available amount [4].

Optimization problems can be generally classified, as depicted in Figure 1.1. An objective function can be a function of a single variable for some practical problems. Optimization problems may involve more than one objective function and are known as multi-objective optimization problems. This refers to a problem where two or more objective functions need to be minimized concurrently. In this case, the optimality of solutions is redefined, since global minimal of different objective functions are rarely achieved at the same minimizer. For instance to develop a new component might involve minimizing weight while maximizing strength or choosing a portfolio might involve maximizing the expected return while minimizing the risk [4].

The nature of a problem determines the type of variable to be used in its model. Variables may be real or integer or a combination of the two [1]. Optimization problems may be constrained or unconstrained. In a constrained optimization problem the search space is usually restricted by its constraints. An unconstrained problem is a problem where constraints are absent or omitted. In unconstrained problems, the whole domain of the objective function is the feasible set. Unconstrained problems arise directly in many practical applications and in the reformulation of constrained optimization problems by replacing the constraints by a penalty term in the objective function [4]. Constrained problems arise from applications where there are explicit constraints on the variables which may vary widely from simple bounds to systems of equalities and inequalities that model complex relationships among the variables. The nature of the constraints such as linear, non-linear, convex and the smoothness of the functions such as differentiable or non-differentiable can be used to further classify constrained optimization problems [4].

This thesis deals mostly with unconstrained minimization tasks, formally described mathematically as:

$$
\begin{gather*}
\min _{x} f(x) \\
\text { Given } x \in \mathbb{R}^{n} \text { is a real vector with } \\
n \geq 1 \text { components and } \\
f: \mathbb{R}^{n} \rightarrow \mathbb{R} \text { being a smooth function. } \\
\text { find } x^{*} \in \mathbb{R}^{n} \text { for which } \\
f\left(x^{*}\right) \leq f(x), \forall x \in \mathbb{R}^{n} \tag{1.1}
\end{gather*}
$$

Constrained optimization problems can be described as:

$$
\begin{gather*}
\min f(x) \\
\text { subject to } c_{i}(x)=0 \forall i \in E \\
c_{i}(x) \leq 0, \forall i \in I \tag{1.2}
\end{gather*}
$$

where $f$ and the functions $c_{i}(x)$ are all smooth, real-valued functions on a subset of $\mathbb{R}^{n}$ and $E$ and $I$ are index sets for equality and inequality constraints, respectively. The feasible set is the set of points $x$ that satisfy the constraints [4].

Function classification deals with properties of mathematical function; the objective or constraint functions could be linear or nonlinear [1, 4]. In a given model, if all the functions are linear, it is being referred to as a linear programming model or a linear model. Otherwise it is referred to as nonlinear. The development of a many optimization techniques are based on convex function [1, 4]. A solution approach in optimization consists of two categories: derivatives and derivativesfree approaches [1]. Derivative-based techniques are capable of determining search directions according to an objective function's derivative information. Derivative-based techniques are used in optimizing non-linear neuro-fuzzy models. Examples include: Descent methods; the method of Steepest Descent; classical Newton's method; stepsize determination and conjugate gradient methods. On the other hand, derivative-free optimization concepts are based on nature's intelligence, such as evolution and thermodynamics. Examples include: genetic algorithm; simulated annealing; random search and downhill simplex search.

Differentiability of a function is similar to functions continuity. Differentiability of function is important if the considered technique is derivative-based. For instance, as shown in Figure 1.1, the properties of a single-objective function, unconstrained problem with continuous variables could be nonlinear, convex, and differential.

In addition to the above general classification, function properties such as unimodal and multimodal, are considered in optimization problem domains. A unimodal function is a function with only one peak-optimum solution. Whereas a unimodal function is a function with more than one peak- local or global optima.

The minimization problems described above can be solved using the techniques called local and global optimization techniques. A local search method iteratively improves its estimate of the minimum by searching for better solutions within a local neighbourhood of the current solution. Since local minima are not guaranteed to be global minima, global optimization methods have been developed to search complicated landscapes of multiple local minima. Global optimization is an inherently complex problem since no general criterion exists for determining when the global optimum is reached. The two competing goals of global optimization techniques are called global reliability (exploration) and local refinement (exploitation) [5]. Exploration is an act of searching

Figure 1.1: Classification of Optimization Problems (Adapted from [1, 3])
the entire search space to find a reasonable estimate of the global optimum, whereas, exploitation is searching the immediate neighbourhood of the current solution for better solutions. Most global optimization techniques achieve these two goals by using a combination of a global and a local strategies [6]. This thesis focuses on global optimization techniques.

Once a model has been prepared for a given optimization problem, suitable optimization techniques can be used to find its solution [1, 2, 3, 4]. Optimization techniques can be classified into deterministic and probabilistic as shown in Figure 1.2. Deterministic technique can be applied to problems whose solution search space can be efficiently explored. Probabilistic technique handles situations where the relations between a solution candidate and its fitness are not so obvious, too complicated, or the dimensionality of the search space is very high [2]. There is a general belief that nature provides inherent solutions to the quest for optimality. This belief led to the development of evolutionary techniques (shown in Figure 1.2) that draw inspiration from the processes of natural evolution, especially the principle of survival of the fittest.

A recent development is the class of swarm intelligence techniques which include bees' algorithm that is based on bees' social behaviour, Ant algorithm that is based on ants' behaviour, Particle Swarm algorithm that is based on birds flocking and RBA that is based on cockroach social behaviour. These techniques were developed from the study of various social behaviours of certain natural animals. They have been successful applied to various classes and complexity of

Figure 1.2: Classification of Global Optimization Techniques (Adapted from [2])
optimization problems. However, there is still rooms left for improvement on these techniques. This thesis examines one of the new techniques under swarm intelligence (SI) technique namely RBA. An extensive study of the social behaviour of cockroach swarm and a review of the existing RBA (RIO and CSO algorithms) is carried out in this work. This work investigates the strengths and weaknesses of existing RBA and is aimed at tackling their obvious drawbacks which are slow convergence and trapping into local minima. The aim is achieved by introducing methods, parameters and incorporating new components into the existing RBAs which resulted in the development of variants of RBA with improved speed, swarm stability, balanced exploitation and exploration. The proposed RBA variants were deployed for varying global optimization problems and the obtained results compared empirically and statistically with the existing algorithms. Generally, RBA
variants show an improved performance over the existing one in most cases.
In this work, a multi-valued discrete space cockroach algorithm is also designed to solve optimization problems within discrete value range through the introduction of sigmoid function and an operator into a CSO algorithm for the logical transformation of cockroach positions from a continuous state to discrete.

### 1.2 Statement of the Problem

The global optimization problem is formulated in terms of finding the point $x$ in a solution space set $X$, referred to as a feasible region. A function $f: X \rightarrow T$, called objective function, locates a minimum or maximum. $T$ is a any ordered set, usually a subset of $\mathfrak{R}$. $x$ could be a continuous variable vector and $f$ a continuous real-valued function. We represent the global optimal solution as $x^{*}$ and the corresponding global optimization function value as $f\left(x^{*}\right)$ or $f^{*}$.

The set $X$ is normally a subset of $\Re^{n}$ defined by constraints $c_{i}(x) \geq=\leq 0$, where $c_{i}$ is a set of $m$ possibly nonlinear functions of $x$ and $\leq,=$ and $\geq$ are relations in $\{\leq,=, \geq\}$. The extremal point $x$ can then be written as $\left(x_{1}, \ldots, x_{n}\right)$, and the $x_{i}$ 's are called decision variables. The domain $X$ is defined within the upper and lower limits $\left(x^{L}, x^{U}\right)$ of each dimension; variable bounds can be expressed as $x^{L} \leq x \leq x^{U}$ where $\left(x^{L}, x^{U} \in \mathfrak{R}^{n}\right)$. Variables may be constrained to only take integer values $x_{i} \in \mathbb{Z}$ for all $i$ in an index set $Z \subseteq\{1, \ldots, n\}$.

We consider minimization problems, described in equations (1.1) and (1.2) in this thesis; using RBAs as global optimization techniques. The shortcomings of the existing RBAs are addressed, these are slow convergence and entrapment in local minima. The shortcomings are addressed by improving the searching capabilities of the algorithms via the incorporation of parameters, components, and features that enhance both exploration and exploitation.

### 1.3 Aim and Objectives of the Study

### 1.3.1 Aim

The research work aimed to improve existing RBAs with new components, operators and parameters in order to evolve improved variants of RBA.

### 1.3.2 Objectives

The specific objectives of the study are as follows:

1. To propose improved RBAs from the existing RBA.
2. To make RBA a global optimization technique with improved convergence on global optima, through the extension of its models.
3. To design and test adaptive RBAs based on methods and models that have been proven to be successful when applied to other evolutionary techniques.
4. To design and test multi-valued discrete space RBA for solving global optimization problems with any discrete values, based on the methods that have been successfully applied to other SI techniques.
5. To evaluate the robustness of the proposed RBA variants with standard global optimization test problems and comparing the obtained results with those in the literature.

### 1.4 Methodology

The proposed improved RBA variants were tested on global optimization problems. The empirical results were analysed statistically and compared with existing algorithms to show the superiority of the improved RBAs over the existing algorithms in most cases. Performance evaluation criteria measures used to evaluate algorithms include: mean function evaluations, run-time and success performance.

### 1.5 Contributions to Knowledge

In this thesis, the development of methods for extending existing RBAs were carried out, and their abilities are enhanced to locate an objective function minimizer. New components, parameters and methods were incorporated into the RBAs to improve swarm stability, speed, searching capabilities and population diversity which resulted in new RBAs. Also the design and implementation of a multi-valued discrete space RBA that can be used to evaluate optimization problems with any discrete range value was achieved. The major contributions of this thesis are as follows:

1. A stochastic constriction factor was introduced to CSO to develop a stochastic constriction cockroach swarm optimization algorithm.
2. A partial differential equation for migration was used to mimic migration behaviour when a cockroach is hungry and needs to move to an available food source. An improved cockroach swarm optimization was proposed.
3. The Euler method in numerical analysis was used to improve the find dark and friend components of RIO and a dynamic step-size roach infestation optimization algorithm was proposed.
4. A partial differential equation for dispersion was introduced to RIO to encourage the dispersion of cockroaches whenever there is overcrowding.
5. Predator-prey evolution with blend crossover and mutation method was introduced into CSO to mimic the cannibalism and reproductive behaviour of cockroaches. The technique enhances a balance of exploration and exploitation, in such a way that the balance is selfadaptive. Self-adaptation causes populations to diverge or converge to a better region within the given search space.
6. A multi-valued discrete space CSO was introduced to offer solutions to optimization problems in any discrete range.

### 1.6 Scope of Study

The study was focused on using some techniques for performance enhancement of the existing RBAs in offering solutions to global optimization problems. Performances of the improved RBAs were evaluated with standard global optimization benchmark problems; the results were statistically analysed and compared with the results of existing algorithms.

### 1.7 Thesis Outline

In the subsequent chapters, we will show the theoretical framework of the research, a review of existing studies, and the methods adopted in improving the existing work to evolve new variants of RBAs. The improved RBAs and application to global optimization problems with empirical results are also presented. The summary of the organization of the remaining part of the thesis is given below:

Chapter 2 gives an introduction to evolutionary computation and swarm intelligence, followed by a review of the social behaviour of cockroaches. Existing works related to improvements and extensions are discussed.

Chapter 3 presents the methodologies engaged in the improvement and extension of the existing RBAs to evolve new and more efficient algorithms.

Chapter 4 shows experimental settings, parameter selection, the statistical analysis tool engaged, the performance evaluation criteria and the global optimization problems solved are also presented.

Chapter 5 presents the improved algorithms with their respective experimental settings, simulation results and comparison results with existing algorithms.

Chapter 6 gives a discussion on the findings of the thesis and the conclusions with a summary of findings of the thesis. Suggestion for future research is also presented.

Finally, the unconstrained test problems used in the study are presented in Appendix A.

## Chapter 2

## Literature Review

### 2.1 Introduction

This chapter reviews some of the related terms to swarm intelligence. A brief discussion of computational intelligence and evolutionary computation is presented. Emergent behaviour of social animals is discussed followed by a discussion of swarm intelligence techniques. A review of cockroach swarm foundation is given, followed by the presentation of existing RBAs and related works.

### 2.2 Computational Intelligence

Computational Intelligence (CI) can be described as a set of techniques inspired by natural metaphor to provide solutions to difficult real world problems that conventional approaches have failed to tackle [7]. CI essentially includes Fuzzy logic systems (FLS), Neural Networks (NNs) and Evolutionary Computation (EC) [7]. CI also embrace techniques that stem from the above three or gravitate around one or more of them. Examples are: SI and Artificial immune system which can be seen as a part of EC. The Dempster-Shafer theory, chaos theory and multi-valued logic can be seen as off-springs of FLS [7, 8]. Probabilistic methods such as belief networks are frequently used with CI paradigms. Each of the CI paradigms has its origin in biological systems [7, 8].

EC defines a number of population-based methods and uses a combination of random variation and selection to offer solutions to problems [9]. It models natural evolution including genetic and behavioural evolution, and populations of individuals. Different classes of EC algorithms have been developed, including SI algorithms that are inspired by social behaviour of animals and insects; Genetic Algorithm (GA) which model genetic evolution; genetic programming (GP)
which is based on GA but with individual programs represented as trees; evolutionary programming (EP) which is derived from the simulation of adaptive behaviour in evolution; evolutionary strategies (ES) which are geared towards modelling the strategic parameters that control variation in evolution and differential evolution (DE) which is similar to GA but differing in reproduction mechanisms used.

EC has many application areas including data mining, combinatorial optimization, fault diagnosis, classification, clustering, scheduling and time series approximation [7]. Barricelli began the simulation of evolution in the 1960s [10, 11]. He started by using evolutionary algorithms (EA) and artificial life, with later advances to his work being made by Fraser who made a lot of contributions on simulation of artificial selection. Through Rechenberg who applied ES to solve complex engineering problems in the 1970s, artificial evolution (AE) became an extensively used and popular optimization technique [12]. GA was made popular by John Holland [13]. EA is now very popular and has been applied to solve multi-dimensional optimization problems efficiently [14].

### 2.3 Swarm Intelligence

SI provides solutions to optimization problems that are motivated by social animals' collective behaviour [15]. Animals swarming has been an area of interest attracting many researchers. The mechanisms that control the social insects and animals' behaviour remained amazing; the animals move in a group, turn together, flow around obstacles and are very clever in their movements [16, 17]. By cooperating, the group is able to achieve complex tasks, despite the fact that the individuals in these colonies are non-sophisticated. Examples of swarms of insects and animals are depicted in Figure 2.1.

### 2.3.1 Emerging Behaviour in Social Animals

Social animals' collective behaviour is self-organised with no central control [15]. For instance, the trail-following behaviour of insects has resulted in efficient solutions to difficult problems such as finding the shortest route to a food source among innumerable possible paths. The act of searching for food is referred to as foraging, which is an emergent behaviour where the swarm finds and exploits good food sources, and adaptively moves to good new sources as current ones become depleted [16]. Flocking represents group movement as seen in bird flocks and schools of fish in nature. A flocking model was first proposed by Craig Reynolds [18] as a bio-inspired computational model for simulating the animation of a flock of entities called boid. In a flocking model, each boid reacts equally to its neighbouring mates in the flock, and to its environment while

Figure 2.1: Swarm of Insects and Animals [19]
making its own decisions. The decision is based on its movement according to a small number of simple steering rules. Perhaps the most visible phenomenon of swarm intelligence is the travelling behaviour of groups (flocks, schools, swarms, herds, etc) of individuals.

Basic swarm models are controlled by three simple rules namely separation, alignment and
cohesion [18]. The separation rule allows short range repulsion to avoid neighbours crowding together during the flocking process. The alignment rule enables individuals in a swarm to steer towards an average heading of one's neighbours, while the cohesion rule considers the long range attraction whereby individuals in a swarm steer towards the average position of one another [18]. Swarming provides some advantages such as flexibility, robustness, and self-organization. SI is flexible, a group can adapt promptly to a changing environment. SI is robust, a group can still perform necessary tasks when one or some individuals fail. SI is self-organized because a group needs little or no supervision or top-down control [18, 20]. Self-organization is a crucial aspect emanating from the collective behaviour of social animals that results into emergent manifestations. The concept of self-organization is presented in section 2.3.2.

### 2.3.2 Self Organization in Social Animals

Self-organization (SO) finds application in different fields of study, such as chemistry, physics, biology, linguistics, economics, robotics and computer science. The idea of SO springs from the world of physical chemistry and signifies a process whereby simple local interactions among simple entities produce a high level structure. According to Dario and Claudio [20] a good examples of SO include the appearance of geometric patterns in reaction-diffusion chemical systems, the formation of snow crystals, and the appearance of moving objects within Conway's Game of Life. The resulting global patterns are emergent and more than the sum of constituent parts. The biological world proliferate in collective trends of significant adaptive roles, such as the construction of nests, coordinated collective movement, communication etc. The entities involved rely on simple rules and local information without a global plan or central coordinator, and are dynamic to malfunction or the divergence of some individual. The principle of SO can be used to describe the biological collective phenomenon that ended at structures and functionality that is far beyond the abilities of the entities involved [20].

SO is built on two opposing forces of attraction and repulsion; these forces are termed as positive and negative feedback [21]. Feedback occurs when a measure in a system is fed back into the system to enhance or reduce the extent of the same measure. The interplay of positive and negative feedback results in the equilibrium of self-organization. May shows that positive and negative feedback can display unexpected adjustments or divergence that influence the pattern or the functionality at global level [22]. The interaction between animals happen by means of cues and signals. A cue is an unplanned indicator that can be picked up by animals such as trail-following. The perceiving entity will choose to follow the cue: positive or negative feedback. A signal is an intentional indicator done consciously to affect the behaviour of other receiving animals. Examples are: waggle dance in bees to give food information to others and the alarm cry of birds when a
predator is in close proximity [20].
SO in social animals often requires direct and indirect interactions among them. The indirect interactions that occur between two individuals when one of them modifies the environment and the other responds to the new environment at a later time are called stigmergy. This is a social communication via modification of the environment; the result of work by an entity affects the action of another entity. Pierre-Paul Grassse introduced the concept of stimergy in the 1950s when he explained that indirect communication takes place among social insect groups. A famous example of stigmergy is the pheromonal communication among ants, whereby ants engaging in certain activities, leave a chemical trail which is then followed by their colleagues. Ants, termites and bees, among many other insect species, are known to have a complex social structure (see Figure 2.2. Stigmergy is a form of cue-based communication which is better described with terms such as aggregation, foraging, clustering, nest construction and division of labour [20, 23].

1. Aggregation: Aggregation is an example of self-organization driven by positive and negative feedback. Aggregation refers to a collection of social agents where individual agents behave without central control and each of these agents show emergent behaviour due to interactions with one another and in response to their environment resulting in a global pattern.
2. Foraging: Stigmergy enhances the effectiveness of group foraging. Ants lay a pheromone trail that can be used to choose a path, find the shortest one and established a link between the food source and the nest [20]. Locating food sources depend on the deposition of pheromones by individual ants. In the natural environment, the initial behaviours of a colony of ants in looking for a new food source is for individual ants to roam at random. When an ant find an appropriate food supply it will return to its colony after having laid pheromone trails. Subsequent ants setting out to search for food will sense the pheromone laid down by their precursors, and this will persuade them as to which path they will take up. Pheromone trails evaporate quickly. If the food source is nearby, the first ant to find this source will return quickly, also other ants that take this route will also return quickly. The best routes will enjoy a greater regularity of pheromone laying in a short time, becoming strongly fancied by other ants [16, 24].
3. Clustering and sorting of objects are part of emergent behaviours exhibited by insect species. Examples include the clustering of corpses of dead ants into cemeteries and the arrangement of larvae into similar-age groups (brood-sorting), for instance, in Leptothorax unifasciatus ant colonies, the young ones are organized into concentric rings called annuli [16, 24]. Each ring comprises young of a different type. The youngest (eggs, and micro-larvae) are clustered together in the central cluster. Outwards from the center, progressively older groups of
larvae are encountered. Also, the spaces between these rings increase as one move outwards [16, 24]. In cemetery arrangement, certain ant species are identified to gather their dead into piles, each piles keep a minimal distance from each other. In this manner, corpses are separated from the living environment, and no longer an impediment to the colony [24].
4. Construction: The extraordinary united behaviour that leads to the construction of wasp nests, termite mounds and bee hives are shown in Figure 2.2. Such structures amazes observers when trying to picture how such simple minds can lead to such creations. Stigmergy is the key to such construction [16, 20].

Figure 2.2: Termite Mound and Bees Hive [25, 26]
5. Division of labour: In the insect community, several insect species display division of labour and specialization where particular entities perform various activities simultaneously [20]. Example are seen in the bees family where different categories of bees carry out different assignments simultaneously.

The emergent and collective social behaviours of different animals and insects are modelled into algorithms termed SI techniques which are now very prominent in solving optimization problems.

### 2.3.3 Swarm Intelligence Techniques

Optimization techniques inspired by SI have attracted interest and gained popularity and attention because of their flexibility, versatility and efficiency in solving real world applications. The techniques are described by the working mechanism that imitates the collective behaviour of social animals in a group where there is no central coordination. Since optimization is everywhere, SI algorithms are applicable across all discipline. People are always optimizing something, either to
minimize the cost, time and resources or to maximize profit, output, performance and efficiency. Examples of SI techniques inspired by social entities, animals and insects' behaviours are shown in Table 2.1. PSO is one of the most popular SI technique in the literature; it is briefly described in section 2.3.4.

Table 2.1: Swarm Intelligence Techniques

| NO | Algorithm | Author(s) | Year | Inspiration |
| :---: | :---: | :---: | :---: | :---: |
| 1 | Particle swarm optimization (PSO) | Kennedy and Eberhart | 1995 | Bird flocking and fish schooling [27] |

### 2.3.4 Particle Swarm Optimization

The inspiration of PSO is from the coordinated interaction of birds flocking and fish schooling [27, 45, 46, 47, 48]. It was originally introduced in 1995 by Eberhart and Kennedy [27]. PSO is a swarm of particles where a particle is a prospective solution to a problem that requires a solution. Individual particles emulate the success of one another based on socio-cognitive factors as they flow through the hyper-dimensional search space of the problem and change particles position in the search region [9, 27, 45, 46, 47, 48]. Individual particles make decisions based on their experience with the environment through individual learning called the cognitive component and experience with their neighbours through cultural transmission which is referred to as the social component. The decision making based on the local interaction with the immediate environment and neighbours result to emergent behaviour of particles in a swarm [21, 50].

The initial values of the PSO control parameters (cognitive factor, social factor and inertial weight), the swarm size, and the maximum iteration number determine the success of the algorithm in finding a global optimum. The velocity of particle is $v_{i}$, its present position is present $t_{i}$, the local and global best solutions are pbest $t_{i}$ and gbest $_{i}$ respectively, rand () is a number that is picked randomly between $(0,1)$ and the learning factors are $c 1$ and $c 2$.

The computational steps given below show the PSO algorithm in the simplest form.

1. Initialize particle
2. Compute fitness value
3. Calculate particle velocity by equation

$$
v_{i}=v_{i}+\mathrm{c} 1 * \operatorname{rand}() *\left(\text { pbest }_{i}-\text { present }_{i}\right)+\mathrm{c} 2 * \operatorname{rand}() *\left(\text { gbest }_{i}-\text { present }_{i}\right)
$$

4. Update particle position by equation
present $_{i}=$ present $_{i}+v_{i}$
5. If termination condition is reached STOP otherwise return to step 2

PSO has offered solutions to several optimization problems in the literature which include: Power and management processes [51, 52], and combinatorial optimization problems [53].

### 2.3.5 Discrete Particle Swarm Optimization

The PSO algorithm for combinatorial optimization problems (COP) was first presented by Kennedy and Eberhart [54] where binary sequences were used to represent particles. Velocity of the particle is expressed by the number of bits changed per iteration, or the distance between the
particles at different times [54]. Particle trajectories are changes in the probability that a coordinate assumes value zero or one [54]. PSO continuous space was transformed into states zero or one using sigmoid function.

$$
\begin{gather*}
s\left(x_{i j}\right)=\frac{1}{1+\exp ^{-} x_{i j}} \\
x_{i j}=\left\{\begin{array}{r}
1 \text { if } \operatorname{rand}() \leq \frac{1}{1+\text { exp }^{-} x_{i j}} \\
0 \text { otherwise }
\end{array}\right. \tag{2.1}
\end{gather*}
$$

$i=1 . . N, j=i . . D$, where $N$ is the swarm size, $D$ is the dimension size and $\operatorname{rand}()$ is a randomly generated number between zero and one [54, 55, 56]

The original binary PSO was modified by many researchers in the literature, to suit more than two valued problems including [55, 56, 57]. Osadciw and Veeramachaneni presented a multi valued discrete PSO [55] where transition of particle position is probabilistic like binary PSO [54] described above. Osadciw and Veeramachaneni used sigmoid with additional operators for logistic transformation of particle states. The range of variable is from 0 to $M-1$, where $M$ denotes number base system which can be binary, ternary, denary etc.

$$
x_{i}=\operatorname{round}\left(s\left(x_{i j}\right)+(M-1) \times \sigma \times \operatorname{randn}(1)\right)
$$

The number is rounded to the closest discrete variable with the end point fixed. where, a sigmoid

$$
\begin{gather*}
s\left(x_{i j}\right)=\frac{M}{1+e^{-} x_{i j}}  \tag{2.2}\\
x_{i j}=\left\{\begin{array}{r}
M-1, \quad \text { if } x_{i j}>M-1 \\
0, \quad \text { if } x_{i j}<0
\end{array}\right. \tag{2.3}
\end{gather*}
$$

Some other methods, different from the sigmoid function described above were used in different SI techniques to discretize a continuous state by transformation of values into a number of possible states. This includes Random key [58, 59], smallest position value [60, 61], modified position equation [62, 63], great value priority [64], and nearest integer [65].

### 2.3.6 Swarm Intelligence Techniques for Discrete Optimization Problems

Real world optimization problems include diversity of issues in scheduling, COP, transportation, inventory planning, production planning, communication operations, computer operations etc. Section 2.3.7 gives a brief discussion on the SI techniques for the travelling sales-man problem (TSP).

### 2.3.7 Swarm Intelligence Techniques for TSP

TSP is one of the most popular COP which can be described as given a set of cities, and distances between the cities; the goal of TSP is to find the shortest tour by visiting every city only once and returning to the starting city [66, 67, 68, 69]. A situation where the distance between two cities does not depend on the direction is referred to as a symmetric TSP, and if otherwise asymmetric. TSP finds application in various real life situations such as vehicle routing, robot control, chronological sequencing, x-ray crystallography, logistics and automatic drilling boards [66]. To improve several optimization methods in recent years, TSP has been considered for comparison [66]. Many studies on SI for TSP have been presented, including ACO [70], dynamic Gaussian process regression [68], and PSO [66, 67].

### 2.3.8 TSP Formulation

Supposing the number of cities to visit is $n$, the distances between cities are stored in a distance matrix (costs) Dmat $=d_{i j}$ where $d_{i j}$ is the distance between city $i$ and city $j,\left(i, j=i_{1}, i_{2}, i_{3} \ldots i_{n}\right)$. Finding the permutation of $\left(i_{1}, i_{2}, i_{3} \ldots i_{n}\right)$ integers from 1 to $n$ which minimize the expression: $d_{i 1 i 2}+d_{i 2 i 3}+d_{i 3 i 4 \ldots}+d_{\text {inil }}$ is the problem to be optimized. If $d_{i j}=d_{j i}$, the problem is symmetric otherwise asymmetric [66].

Basically in TSP, a tour can be described as the traverse of a salesman across cities, visiting each city once and returning to starting city. The distance between the cities is computed by minimizing the tour length. A tour can be expressed using a recurring permutation $\pi$ where $\pi_{i}$ denotes city $i$ on the tour. TSP is the optimization problem to find a permutation $\pi$ that minimizes the tour length as shown in equation 2.4 [77].

$$
\begin{equation*}
\sum_{i=1}^{n} d_{i} \pi_{i} \tag{2.4}
\end{equation*}
$$

Other formulations of TSP, different from permutation problems are graph theoretical problems, integer programming, and linear programming. TSP can be formulated as a graph theoretical problem where it is represented as a complete graph $G=(V, E)$ [71]. The goal is to find a Hamiltonian cycle which visits each graph node exactly once, with the least weight in the graph [68, 71]. Cities are denoted by the node set $V=\{1,2, \ldots n\}$ and each edge $e_{i} \in E$ is the distance between nodes. This is an associated weight $w_{i}$ to each edge $e_{i} \in E$.

TSP formulation as integer programming is based on assignment problems with sub-tour elimination constraint as shown below:

$$
\begin{equation*}
\min \sum_{i=1}^{n} \sum_{j=1}^{n} d_{i j} x_{i j} \tag{2.5}
\end{equation*}
$$

$$
\begin{gathered}
\text { Subject to } \sum_{i=1}^{n} x_{i j}=1, j=1, \ldots, n, \\
i \neq j \\
\sum_{j=1}^{n} x_{i j}=1, j=1, \ldots, n, \\
x_{i j}=0 \text { or } 1
\end{gathered}
$$

sub-tour eliminated.
Solution matrix $X=\left(x_{i j}\right)$ of the assignment problem denotes the tour or a collection of subtours. Only the edges that correspond to elements $x_{i j}=1$ are on tour. The sub-tour elimination constrained added restricts the solution to only proper tours [71].

TSP formulation as linear programming is expressed as:

$$
\begin{equation*}
\min \sum_{i=1}^{m} w_{i} x_{i}=W^{T} X \tag{2.6}
\end{equation*}
$$

Subject to $x \in S$
where $m$ denotes number of edges $e_{i} \in G$ (Hamiltonian cycle $G$ ), $w_{i} \in W$ denotes the weight of edge $e_{i}$ and $X$ denotes the incidence vector showing presence and absence of edges in the tour [71].

Among the existing SI techniques shown in Table 2.1, this thesis focuses on RBA (RIO and CSO). A review of cockroach social behaviour and existing RBA is presented in sections 2.4 and 2.5

### 2.4 Foundation of Cockroach Swarm

Cockroaches are social insects that exhibit extraordinary variations in their social organization; they are versatile in reproductive mode and feeding habits [72]. Cockroaches naturally seek dark shelters that are rich in nutritional resources. They rest in groups in dark shelters and forage at night in search of food and water, and they remain faithful to their shelter as long as there are enough rich resources in their surroundings to exploit [73]. They are insects that are large in size, and can reach nine centimetres in length and weigh about 30 grams. They have relatively small heads with broad and flattened bodies, large compound eyes, a pair of antennae and two pairs of wings [74]. Cockroaches vary in over four thousand different colours and species [72]. Cockroaches are among the most ancient animals on earth [75]. They are the fastest insect on earth, and can run up to twelve feet in a second [75]. The social world of cockroaches is controlled by the chemical called pheromones, and by responding to pheromone stimuli, cockroaches are able to perform some social functions [72].

### 2.4.1 Cockroach Social Behaviours

Cockroaches interact with peers and respond to their immediate environment, and make decisions based on their interactions such as finding a good food source, locating other friends, shelter selection, rapid dispersion when danger is noticed, and eating one another when food is scarce. The emergent behaviour in cockroaches is the result of group-based decision making. Individual cockroaches act mainly on local information received from interaction with their peers and their immediate environment [21]. Different studies, including [73, 76, 77, 78, 79, 80, 81, 82], have revealed the emergent social behaviour of cockroaches. Experiments were carried out by Jeanson and his group [77] where a number of cockroaches were tracked in an enclosed circular arena. It was discovered that cockroaches first exhibit a wall-following behaviour along the edge of the arena and some individual cockroaches choose to explore the central zone of the enclosed arena.

Cockroaches feel the presence of one another via their antennae which are 3 mm long; they perceive each other within a distance of 6 mm , that is, head to head inter-individual distance (see Figure 2.3). They stop and interact with one another and share information on the best food source [77]. In the process more individuals will also stop and join the group, which will eventually lead to aggregation. Jeanson et al., obtained the probability of stopping, for a moving cockroach when N individuals is perceived. It is defined within a detection radius $(1 \leq N \leq 3)$ [77]. The stopped cockroach will aggregate with N individuals $(2 \leq N \leq 3)$ detect a moving cockroach within the detection radius. Cockroaches prefer to aggregate, it was discovered that the probability of moving away from a group is very low. The probability per unit time of stopping when encountering N friends is $1 / T_{\text {stop }}, N: 0.49 / \mathrm{s}$ for $(\mathrm{N}=1), 0.63 / \mathrm{s}$ for $(\mathrm{N}=2)$ and $0.65 / \mathrm{s}$ for $(\mathrm{N}=3)$ [77].

Halloy et.al., [76] and Ame et.al., [78] carried out experiments to show collective decision making of groups of cockroaches on shelter selection. Halloy et. al., performed their experiment with both natural cockroaches and artificial cockroaches (robots scented with a concentration of real cockroach odour). The natural and artificial cockroaches were equally attracted to one another [76]. In the series of experiments performed on shelter selection, both natural and robot cockroaches interacted, and showed a preference for aggregating in dark shelters, which supports the hypothesis that cockroaches make use of just two pieces of information (how dark the place is and how many other cockroaches are there) when choosing where to go. Likewise, it supports the hypothesis that collective behaviour is aggregated from simple decentralized behaviour. Halloy et al., [76], Jeanson et al., [77] and Ame et al., [78] concluded that cockroach aggregations are selforganized systems, resulting from interactions between individuals following simple rules based on local information.

Cockroaches prefer to swarm on food rather than to dine alone. The experiment carried out by Mathieu Lihoreau and his group at Queen Mary, University of London [82] showed that cock-
(a)

12 mm
Figure 2.3: (a) Cockroach detect each other by head to head inter-individual distance of less or equal to 6 mm . (b) A moving cockroach A encounters a stopped cockroach $B$ at a maximum of 12mm (Adapted from [77]).
roaches follow a crowd when it comes to dining. In the experiments, they presented two piles of food in a closed arena with a number of cockroaches. They discovered after a while that the cockroaches packed themselves on only one pile, instead of dividing into two groups. The more crowded and cockroach infested the food, the more cockroaches were joining the excessive fling. The more the cockroaches gathered on a pile of food the more attractive the food becomes and the longer they stayed at the source [73, 82]. Figure 2.4 shows a number of cockroaches dinning together on a piece of bread.

Miller and Koehler [81] investigated trail following behaviour of cockroaches. Cockroaches leave chemical trails in their faeces which transmit bacteria onto surfaces. They also emit airborne pheromones for swarming and mating. The use of chemical trails for directional orientation is widespread among social insects. Cockroaches exhibit trail-following behaviour, by using physical landmarks and visual clues for directional orientation during the daylight hours, while directional response to odours and chemical stimuli allow for free movement in the dark [81]. The German cockroach is a gregarious, nocturnal insect whose directional locomotory behaviour is influenced by chemical compounds found in their faecal material. It was discovered that German cockroaches leave and return to their harbourage using chemical substances in their faeces for navigation [81].

Figure 2.4: Swarm of cockroaches [83]

Miller and Koehler [81] carried out an experiment, where strips of chromatography paper that had been treated with faecal extract were used to evaluate cockroach trail-following behaviour. Chromatographic paper was cut into uniform strips. For each test, two strips were individually treated; one with a solution of methanol and faecal extract, the other with an equal amount of methanol. These strips of paper were arranged in a shaped configuration and taped to the floor of the test arena. For each replicate of the test, a harbourage was placed at the vertex of the V configuration and opened to release one cockroach. The cockroach was allowed to exit and follow its own course. Each test used 10 cockroaches, and after exiting the harbourage, cockroach movements were captured on a low-light video surveillance camera and recorded. The results of their experiment supported the hypothesis that chemicals in the cockroach faecal material did influence directional orientation [81]. Other cockroaches follow these trails to discover sources of food and water, and also discover where other cockroaches are hiding. Thus, cockroaches can exhibit emergent behaviour in which group or swarm behaviour emerges from a simple set of individual interactions. Some of the emergent behaviour of cockroach are presented below.

### 2.4.2 Foraging

Cockroaches use recruitment mechanisms to forage. The recruitment mechanisms can be either direct or indirect [50], mass recruitment via a faecal chemical trail is a good example of indirect recruitment. The recruiter and the recruits are not in physical contact with each other, the recruiter deposits faecal pheromone on their way back from a profitable food source and recruits simply follow the trail; communication is via modulation of the environment. Using a direct recruitment mechanism the recruiter transfers information to the recruits [50]. A good example of a direct recruitment mechanism is when a cockroach comes within a detection radius of another cockroach agent via an encounter with their antennae, then perceive each other within a distance of 6 mm , (a cockroach antennae is 3 mm long) that is head to head inter-individual distance. There is a probability that the cockroaches will stop, socialize and communicate their knowledge of the search space to one another [77].

The foraging behaviour of recruited individuals is influenced by positive feedback enhanced by a faecal trail [82] which leads to the selection of a food location and exploitation/exploration of most the rich food sources. Food closest to harbourage is exploited first, and when depleted, cockroaches forage further and explore other sites [72]. Socially foraging cockroaches, locate food sources and eat the food at the food source [73]. Australian soil-burrowing cockroaches forage, locate food source and transport or relocate a quantity of food to their harbourage. The gathered food is eaten by both the forager and any young offspring in the nest [72]. Food relocation is a proximate mechanism for obtaining and securing food, which helps the cockroaches feed at their leisure in a location relatively safe from predators [72].

### 2.4.3 Exploitation and Exploration

Exploitation is the use of existing information while exploration is the collection of new information about food sources [50]. When a cockroach exploits a profitable food source, there may still be other, undiscovered, profitable sources that are yet to be exploited [50]. One of the mechanisms for exploration is food foraging. Cockroach forage for food locations near their shelter first, and when that food is depleted, they forage further and explore new food locations. Another mechanism which is a kind of direct mechanism is called vigilance behaviour, which occurs at intervals of time when cockroaches sense danger or a predator and disperse rapidly [72]. Cockroaches rapidly disperse to different locations, this helps them to explore and exploit other areas in the search space for good solutions. Vigilance behaviour enhances high levels of diversity as cockroaches disperse to several locations in the search space and explore the new sites; this helps to prevent local convergence.

### 2.4.4 Shelter Selection

Cockroaches make use of different criteria for harbourage site selection. Mainly, cockroaches prefer a shelter close to nutritional sources; a site with adequate food and water [72]. The shelter's physical properties such as darkness, height, temperature, texture, orientation of surfaces and the size of the harbourage are influential [72, 73]. The body size of the cockroach also determines shelter selection, as cockroaches may segregate if the harbourage is not spacious enough in terms of cockroach population and shelter height [72]. Cockroaches move to new shelter when the previous shelter is overcrowded or food is depleted [73]. Exploring cockroaches perceive an occupied shelter and switch from search mode to join and settle. The larger the cockroach population the more new cockroaches are joining the group and by this retention effect an aggregation is formed, which eventually leads to the selection of a unique shelter by the entire group [73, 82].

### 2.4.5 Aggregation

Cockroaches aggregate as a result of attraction of the chemical material deposited on their faeces [84]. Faecal material is identified as the source of a cue [85, 86]. Mechanisms by which a group of cockroaches may gather, was suggested by Kavanaugh [87] as independent individual responses to environmental gradients. This leads to aggregation in an abiotically optimum location; and the individual response to stimuli provided by other individuals, leads to group formation at a common location. Jeanson et al., and Halloy et al., later re-investigated and experimented with this approach [76, 77] and concluded that cockroach aggregations are self-organized systems, resulting from interactions between individuals following simple rules based on local information.

Cockroach larvae exhibits a collective complex behaviour that results in aggregation; the individual decisions of cockroaches transform the collective behaviour of the entire group, which support the hypothesis that collective behaviour is aggregated from simple decentralized behaviour [77].

Female cockroaches exhibit oviposition behaviour, they deposit their oothecae (eggs) with a drop of genital fluid (oviposition pheromone) close to a food supply [88]. The pheromone attracts other females to lay their eggs in the site which eventually results in a cluster of eggs which hatch to form an aggregation of cockroaches [88].

### 2.4.6 Nourishment and Food Location Selection

Cockroach decisions on food source depends on the nutritional values, distance from the shelter and presence of conspecifics [73]. Aggregation at food sources is enhanced by a social facilitation process for feeding, as cockroaches in large populations feed longer than those in small population
group sizes [73, 82]. Cockroaches exhibit the simplest form of food related grouping behavior; they, cue on conspecifics for food information [76, 89].

Willeyto et al. [90] described the nourishment behaviour as a means of signalling to the unassociated individuals the location of food supply. Cockroaches forage from their shelter to the location of food supply and return back to their shelter. The food patches closer to the shelter are exhausted first before foraging further [91, 92]. Trail pheromones facilitate the movement of cockroaches from their shelter to the food location. The size of a cockroach aggregation is ultimately determined by the availability of adequate food and water [84].

Favourable habitats can result in enormous populations, with the constant renewal of food resources in the surroundings of the shelter amounting to large aggregation [72]. Cockroaches leave behind at the feeding sites a variety of residue in the form of saliva, glandular deposits and faecal pellets, which put a mark on the site and make it more attractive than an unmarked and unvisited site [72]. The traffic of conspecifics makes the place visible for other foraging cockroaches, whether cockroaches are present at the marked site or not.

Williams et al., Cockroaches ecology, behaviour and natural history, states that, cockroaches can feed on anything such as soap, paper, clothes, faeces, human food, their cast-off skin and egg capsules, and will eat one another, with the strong ones eating the weak [72]. When a cockroach is hungry and there is no food, in the surrounding area, the strong ones will eat the weak ones.

Cockroach social behaviours were modelled and presented in the literature as SI optimization algorithms that establish the relationship between social behaviour and optimization paradigms and explored the processes therein to solve optimization problems [34, 35]. The RBAs found in the literature are presented in section 2.5

### 2.5 Roach-based Algorithms

### 2.5.1 Roach Infestation Optimization

RIO was originally introduced by Haven et al., [34] as a cockroach inspired algorithm. RIO was adapted from the traditional PSO algorithm, and therefore it has some elements similar to PSO. A hungry version of PSO and RIO were also described [34]. It is assumed that cockroaches begin as individuals and are ruled by only the find dark behaviour [34]. Whenever a cockroach agent encounters another cockroach agent, it stops and socialises and shares information about the darkest known location. "An encounter is defined as two cockroaches coming within 6 mm of one another and a collision is defined as when a moving cockroach encounters a stopped cockroach that is a member of an aggregate" [77]. When a cockroach is hungry it leaves friends and comfortable shelter and searches for food [72, 34]. A hunger counter is defined for each cockroach agent, once
it is reached, the cockroach is transported to a food location within the search region. The find food behaviour causes population diversity, and prevents local convergence [34]. RIO is described with three behaviours [34]:

1. Find dark: "Cockroaches search for the darkest location in the search space and the fitness value is directly proportional to the level of darkness" [34]. Find dark behaviour:

$$
\begin{equation*}
v_{i}=c_{0} v_{i}+c_{\max } R_{1}\left(p_{i}-x_{i}\right) \tag{2.7}
\end{equation*}
$$

where $v_{i}$ is the velocity of the $i t h$ agent, $x_{i}$ is the current location found by the ith agent, $p_{i}$ is the best location found by the $i$ th agent, $c_{0}, c_{\max }$ are cockroach parameter, $R_{1}$ is a vector of uniform random numbers, and $\left(p_{i}-x_{i}\right)$ is a velocity change in the direction of the darkest known location for that agent.
2. Find friend: If a cockroach comes within a detection radius of another cockroach agent, it will stop, socialize and share information of the darkest known location by setting local location $l$

$$
\begin{equation*}
l_{i}=l_{j}=\arg _{k} \min \left\{F\left(p_{k}\right)\right\}, k=\{i, j\} \tag{2.8}
\end{equation*}
$$

where $i, j$ are the indices of the two socializing cockroaches and $p_{k}$ is the personal best known darkest location. Find darkest model is extended to include find friend behaviour:

$$
\begin{gather*}
v_{i}=c_{0} v_{i}+c_{\max } \cdot R_{1}\left(p_{i}-x_{i}\right)+C_{\max } \cdot R_{2}\left(l_{i}-x_{i}\right)  \tag{2.9}\\
x_{i}=x_{i}+v_{i} \tag{2.10}
\end{gather*}
$$

3. Find food: When a cockroach experiences hunger, it leaves the comfort of friends and shelter to search for food and is taken to a food source $b$ that is positioned randomly in the search region.

$$
\begin{equation*}
x_{i}=b \tag{2.11}
\end{equation*}
$$

Algorithm 1 shows the computational steps of RIO.

```
Algorithm 1 Roach Infestation Optimization Algorithm
    INPUT: Fitness function: \(f(x), x \in R^{D}\)

            if \(f\left(\vec{x}_{i}\right)<f\left(\vec{p}_{i}\right)\) then
                \(\vec{p}_{i}=\vec{x}_{i}\)
            end if
            Compute the neighbours of roach \(i\) as
            \(\{j\}=\left\{k: 1 \leq k \leq N, k \neq i, M_{i k}<d_{g}\right\}\)
            \(N_{i}=\) number of neighbour of \(|\{j\}|\)
            for \(q=1 t o N_{i}\) do
                if \(\operatorname{rand}[0,1]<A_{\text {min }}\{N, 3\}\) then
                    \(\vec{l}_{i}=\vec{l}_{j}=\arg \min _{k}\left\{f\left(\vec{p}_{k}\right)\right\}, k=\left\{i, j_{q}\right\}\)
            end if
            end for
            if hunger \(_{i}<t_{\text {hunger }}\) then
            \(\vec{v}_{i}=C 0 \vec{v}_{i}+\operatorname{Cmax} \vec{R}_{1}\left(\vec{p}_{i}-\vec{x}_{i}\right)+\operatorname{Cmax} \vec{R}_{1}\left(\vec{l}_{i}-\vec{x}_{i}\right)\)
            \(\vec{x}_{i}=\vec{x}_{i}+\vec{v}_{i}\)
            else
                    \(\vec{x}_{i}=\vec{b}\)
                    Relocate food location randomly
                    hunger \(_{i}=0\)
            end if
            if Hungry then
                Increment hunger \(_{i}\) counters
            end if
            Check termination condition
        end for
    end for
```

RIO achieved good results when applied to benchmark functions and compared to PSO [34]. Hendrawan and Murase proposed a discrete RIO for a feature selection problem using a neural network as a predictive tool where each roach was represented by a binary encoding vector and each dimension represented a feature value of 0 or 1 . It is 0 when the corresponding feature is not selected and 1 if otherwise. A mutation operator is used for updating the position of each roach by updating velocity. Two point crossover is used for updating the cognitive and social parts of the cockroach [93].

### 2.5.2 Cockroach Swarm Optimization

ZhaoHui and HaiYan presented cockroach swarm optimization (CSO) which was inspired by the social behaviour of cockroaches [35]. They show cockroach behaviour in three components: chase-swarming, dispersion and ruthless. In the CSO model there is a cockroach cluster containing N cockroach individuals in the D -dimensional search space $R^{D}$ where the ith individual is a representation of a D-dimensional vector $X_{i}=\left(x_{i 1}, x_{i 2}, \ldots, x_{i D}\right), i=1,2, \ldots, N$. Individual cockroach location is a potential solution.

CSO model is presented as [35]:

1. Chase-Swarming behaviour:

Chase-Swarming behaviour is described as each individual $x_{i}$ will chase the local optimum individual $p_{i}$ within its visual scope. Of course, such chasing behaviour also produced cluster simultaneously. There is an assumption, that when an individual is the best one within its visual scope, it will chase the global optimum individual $p_{g}$ [35]. The model is:

$$
x_{i}=\left\{\begin{array}{c}
x_{i}+\text { step.rand. }\left(p_{i}-x_{i}\right), x_{i} \neq p_{i}  \tag{2.12}\\
x_{i}+\text { step.rand. }\left(p_{g}-x_{i}\right), x_{i}=p_{i}
\end{array}\right.
$$

where $x_{i}$ is the cockroach location, step is a fixed parameter, rand is a random number within [0,1],

$$
\begin{equation*}
p_{i}=\text { Opt }_{j}\left\{x_{j}, \text { Suchthat }\left|x_{i}-x_{j}\right| \leq \text { visual }, j=1,2, \ldots ., N\right\} \tag{2.13}
\end{equation*}
$$

where $p_{i}$ is the personal best optimum, visual denotes the visual distance of cockroach, $N$ is the population size.

$$
\begin{equation*}
(i=1,2, \ldots \ldots, N), p_{g}=O p t_{i}\left\{x_{i}, i=1,2, \ldots, N\right\} \tag{2.14}
\end{equation*}
$$

where $p_{g}$ is the global optimum individual.
2. Dispersing Behaviour

Dispersing behaviour is described as when individual cockroach disperses randomly at intervals of time in order to maintain the diversity of current individuals. The model is:

$$
\begin{equation*}
x_{i}=x_{i}+\operatorname{rand}(1, D), i=1,2, \ldots, N \tag{2.15}
\end{equation*}
$$

where $\operatorname{rand}(1, D)$ is a D -dimensional random vector that can be set within a certain range, $D$ is the space dimension.
3. Ruthless

Ruthless behaviour is described as the current best cockroach replacement of the one that has been randomly picked at intervals of time. The stronger eats the weak one. The model is:

$$
\begin{equation*}
x_{k}=p_{g} \tag{2.16}
\end{equation*}
$$

where $k$ is a random integer within $[1, \mathrm{~N}], p_{g}$ is the global best cockroach position.
There is the possibility of CSO falling into local optimum when imitating chase-swarming behaviour due to the formation of cockroach cluster in a location. Dispersing behaviour may keep individual diversity and ruthlessness can improve searching capabilities [35].

### 2.5.3 A Modified Cockroach Swarm Optimization

ZhaoHui introduced an inertial weight $w$ into the chase-swarming component of CSO [94].
Chase-Swarming behaviour:

$$
x_{i}=\left\{\begin{array}{c}
w \cdot x_{i}+\text { step.rand. }\left(p_{i}-x_{i}\right), x_{i} \neq p_{i}  \tag{2.17}\\
w \cdot x_{i}+\text { step.rand. }\left(p_{g}-x_{i}\right), x_{i}=p_{i}
\end{array}\right.
$$

The computational steps of MCSO is shown in algorithm 2 .
CSO algorithm shows competitive results in the literature, where it was applied to some optimization problems and compared to PSO. Its application as reported in the literature includes: solving benchmark functions [35, 94]; Cheng et. al., applied CSO to Travelling salesman problem [95]; ZhaoHui and HaiYan applied CSO to vehicle routing [96]; Wu and Wu proposed a cockroach genetic algorithm for estimating the parameters of biological system in showing the net interactive effect of S-system where cockroach behaviour was imitated and embedded into advanced genetic algorithm to increase exploration and exploitation abilities [97].

### 2.6 Related Works

A vast new algorithms can be constructed by simply introducing some techniques, models and parameters to existing algorithm for performance improvement. For example, an algorithm can be extended with certain techniques, to perform a rapid local search to refine a solution when necessary. Chapter 3 investigates several techniques for constructing improved RBAs; some of the techniques have been proved successful in previous studies when applied to SI and EC algorithms. A constriction factor was initially introduced into PSO by Clerc and Kennedy to avoid swarm explosion, maintain swarm stability, and enhance the convergence of the algorithm in a multidimensional complex space [98]. Other researchers also investigated constriction factors in studies

```

    end for
```

including [99, 100, 101]. The stochastic constriction RBA shown in Chapter 3 was inspired by the studies on constriction factors.

Cai et al., investigated the effect of simple Euler stochastic dynamic step length in PSO [102]. The step length technique improved the searching ability of PSO and maintained a balance between exploration and exploitation. The dynamic step-size adaptation RBA that is presented in Chapter 3 was inspired by studies [102].

Laumanns et al., introduced the basic concept of the predator-prey evolution method [103]. They described a technique that imitated natural predator-prey habits, when a predator kills the weakest prey in its vicinity and a relatively strong prey is created through evolution processes to replace the weak prey. Other studies on this technique include [104, 105, 106, 107, 108, 109, 110, 111]. Chowdury et al., presented a modified predator-prey (MPP) algorithm using blend crossover [104, 109]. The Predator-prey RBA presented in Chapter 3 was inspired by these studies.

SI techniques for transforming a continuous space into binary or multi-valued discrete space in order to offer solutions to discrete optimization problems were investigated in many studies including [54, 55, 56, 57] (See section 2.3.5). A study on multi-valued space discrete cockroach swarm presented in Chapter 3 was inspired by the study carried out by Osadciw and Veeramachaneni on multi valued discrete PSO [55].

## Chapter 3

## Improved Roach-based Models

### 3.1 Introduction

This chapter introduces different methods and models for constructing improved RBAs for global optimization problems. The existing RBA presented in section 2.5 were originally designed to provide solutions to the global optimization problem, that is, finding the best solution among several others. The methods and models introduced in this chapter aims to improve the strength of RBA in achieving the goals of global optimization which is known as exploitation and exploration. The first model called stochastic constriction cockroach swarm optimization model, described in section 3.2.1 is similar to "Clerc and Kennedy's particle swarm-explosion, stability, and convergence in a multidimensional complex space" [98]. It uses a stochastic constriction instead of a static one as shown in section 3.2. The second model, described in section 3.3.1 adds a component, that was constructed using a partial differential equation, shown in section 3.3 to the existing CSO, that was originally designed with three components and is called an improved cockroach swarm optimization. The third model described in section 3.4.1 introduces a simple Euler method expressed in section 3.4 into RIO and is called a dynamic step-size adaptation roach infestation optimization. It is similar to Cai et. al., "stochastic dynamic step length particle swarm optimization" [102]. The fourth model called modified roach infestation optimization, described in section 3.6.1 adds two components to the existing RIO model that was originally made up of three components. The two added components were constructed using a partial differential equation and predatorprey evolution methods respectively as shown in sections 3.5 and 3.6. The fifth Model called an adaptive cockroach swarm algorithm was also constructed by modifying the existing CSO algorithm using a predator-prey evolution with crossover and mutation techniques described in section 3.7. The sixth model, described in section 3.8.1 further extended the existing CSO, using a known technique, shown in section 3.8 to construct a multi-valued discrete space CSO that can be used
for optimization problems with any discrete value or base system (binary, ternary, quaternary etc.). It is similar to Osadciw and Veeramachaneni's multi-valued discrete PSO.

### 3.2 Stochastic Constriction Factor

A constriction factor enhances convergence of an algorithm, and improves both local and global searching abilities. The idea for a constriction factor came from the well-known idea of constriction factor [98, 99, 100, 101] introduced by Clerc and Kennedy into PSO to allow control over the dynamical characteristics of the particle swarm, including its exploration versus exploitation propensities [98].

$$
\chi=\frac{2}{\left|2-\varphi-\sqrt{\varphi^{2}-4 \varphi}\right|}
$$

where $\varphi=c_{1}+c_{2}, \varphi>4.0, c 1$ is the recognition factor and $c 2$ is the social factor. Constant $\chi$ was described by Shi as a constant which is approximately 0.729 and $\varphi$ is commonly set to 4.1 [99]. An algorithm with constriction constant 0.729 is equivalent to algorithm of inertia weight 0.729 with $c 1=c 2=1.49445$ [99]. The comparison study of the effect of the constriction factor and inertial weight on PSO was carried out [100, 101] where it was shown empirically that constriction PSO performs better than inertia weight PSO. This motivated the introduction of stochastic constriction factor (SCF) into CSO algorithm to control cockroach movement during the swarming process (shown in computational steps of section 3.2 .1 below) in order to avoid swarm explosion.

SCF enables the algorithm to avoid explosion in regions outside of the search space. It also enhances local and global searches of the algorithm; a cockroach is able to exploit the local neighbourhood and explore the whole search region. SCF allows the generation of different values as constriction factors in each iteration and was found to be efficient, as revealed through the results of our empirical studies. Our results presented in section 5.2 show improved speed and convergence.

### 3.2.1 Stochastic Constriction Cockroach Swarm Optimization Model

SCF was incorporated into the CSO algorithm to maintain swarm stability and a balance of exploitation and exploration. To achieve this aim, CSO chase-swarming behaviour [35, 94] presented in sections 2.5.2 and 2.5.3 is modified in this work with the introduction of SCF $\xi$. In each iteration, $\xi$ randomly takes values between zero and one. $\xi$ controls entire cockroach movement, not only cockroach position as with inertial weight $w$ of $\operatorname{CSO}$ [94]. In equation (3.1), stochastic

Figure 3.1: Constriction factor constrained cockroach movement within the search region
constriction factor $\xi$ restricts the movement of cockroach swarms within the given search region.

$$
x_{i+1}=\left\{\begin{array}{l}
\xi\left(x_{i}+\text { step.rand } \cdot\left(p_{i}-x_{i}\right)\right), x_{i} \neq p_{i}  \tag{3.1}\\
\xi\left(x_{i}+\text { step.rand. }\left(p_{g}-x_{i}\right)\right), x_{i}=p_{i}
\end{array}\right.
$$

Figure 3.1 depicts the restriction of movement of cockroach within the search space by SCF $\xi$ as $x_{i}$ always approach to $p_{i}$ and $p_{i}$ approach to $p_{g}$. The constant step and randomly generated number rand manages the step size of cockroach in iteration towards the optimum individual. Where $x_{i}$ is the cockroach's present position, $x_{i+1}$ is the new position located by the cockroach, $p_{i}$ is the personal best optimum and $p_{g}$ is the global best optimum.

We proposed a Stochastic Constriction Cockroach Swarm Optimization (SCCSO) for Multidimensional Space Function Problems [112]. The algorithmic steps for SCCSO is illustrated in Algorithm 3 and its computational steps given as:

1. Initialise cockroach swarm with uniform distributed random numbers and set all parameters values.
2. Locate the best position $p_{i}$ and $p_{g}$ using equations (2.13) and (2.14).
3. Perform chase-swarming using equation (3.1).
4. Carry out dispersion behaviour using equation (2.15).
5. Exhibit ruthless behaviour using equation (2.16).
6. Repeat the loop until stopping criteria is reached.
```
Algorithm 3 Stochastic Constriction Cockroach Swarm Optimization Algorithm
    INPUT: Fitness function: \(f(x), x \in R^{D}\)
    set parameters and generate an initial population of cockroach
    set \(p_{g}=x_{1}\)
    for \(i=2\) to \(N\) do
        if \(f\left(x_{i}\right)<f\left(p_{g}\right)\) then
            \(p_{g}=x_{i}\)
        end if
    end for
    for \(t=1\) to \(T_{\text {max }}\) do
        for \(i=1\) to \(N\) do
            for \(j=1\) to \(N\) do
                if \(\operatorname{abs}\left(x_{i}-x_{j}\right)<\operatorname{visual} ; f\left(x_{j}\right)<f\left(x_{i}\right)\) then
                        \(p_{i}=x_{i}\)
                end if
            end for
            if \(p_{i}==x_{i}\) then
                \(x_{i+1}=\xi\left(x_{i}+\right.\) step.rand. \(\left.\left(p_{g}-x_{i}\right)\right)\)
            else
                \(x_{i+1}=\xi\left(x_{i}+\right.\) step.rand. \(\left.\left(p_{i}-x_{i}\right)\right)\)
            end if
            if \(f\left(x_{i}\right)<f\left(p_{g}\right)\) then
                \(p_{g}=x_{i}\)
            end if
        end for
        for \(i=1\) to \(N\) do
            \(x_{i}=x_{i}+\operatorname{rand}(1, D)\)
            if \(f\left(x_{i}\right)<f\left(p_{g}\right)\) then
                \(p_{g}=x_{i}\)
            end if
        end for
        \(k=\operatorname{randint}([1, N])\)
        \(x_{k}=p_{g} ;\)
    end for
    Check termination condition
```

The performance of the proposed algorithm was evaluated on 9 well known high dimension benchmark problems namely Rastrigin, Levy, Sphere, Rosenbrock, Schwefel, Quadric, Griewangk, Ackley and Sum-Square. The problems are described in Appendix A The results of the simulation studies are presented in section 5.2 .

### 3.3 Partial Differential Equation Method for Migration

A partial differential equation (PDE) contains unknown multi-variable functions and their partial derivatives. Problems that involve functions of several variables can be formulated using PDE method. Such problems can be offered solutions by creating a relevant computer model in the form of an algorithm or mathematical equation to capture the behaviour of the system being modelled. Different physical phenomena can be expressed using PDE method.

A PDE for $u\left(x_{1}, \cdots, x_{n}\right)$ function is expressed as

$$
L\left(x_{1}, \ldots, x_{n}, u, \frac{\partial u}{\partial x_{1}}, \ldots, \frac{\partial u}{\partial x_{n}}, \frac{\partial^{2} u}{\partial x_{1} \partial x_{1}}, \ldots, \frac{\partial^{2} u}{\partial x_{1} \partial x_{n}}, \ldots\right)=0 .
$$

When $L$ is a linear function of u and its derivatives, then the PDE is said to be linear. Examples are Laplace, Poisson, Helmholtz, heat, wave, and Klein-Gordon equations.

In this thesis, PDE methods were used to describe behaviours (migration and dispersion). PDE method for migration is discussed in this section while the dispersion method is described in section 3.5. The PDE method for population migration is designed to transport agents in a population from one place to another [113]. The idea comes from the known PDE fundamental solution for migration presented by Kerckhove [113].
PDE migration equation is given as: [114]

$$
\begin{equation*}
\frac{\partial u}{\partial t}=-c \frac{\partial u}{\partial x} \tag{3.2}
\end{equation*}
$$

with $u(0, x)=u_{0}(x)$, parameter $c$ is the controlling speed of the migration. $u$ is the population size, $t$ is time and $x$ is location or position. $u(t, x)$ is the population size at time $t$ in location $x$ while $u(0, x)=u_{0}(x)$ is the initial population distribution

$$
\begin{gathered}
\frac{\partial u}{\partial t}=-c \frac{\partial u}{\partial x} \\
\frac{\partial u}{\partial t}+c \frac{\partial u}{\partial x}=0
\end{gathered}
$$

The characteristic equations are:

$$
\begin{aligned}
& \frac{d t}{1}=\frac{d x}{c}=\frac{d u}{0} \\
& d x-c d t=0
\end{aligned}
$$

By integration, we have

$$
\begin{gathered}
x-c t=\alpha \\
u=u(\alpha) \\
u=u(x-c t) u[t, x]=u_{0}[-c t+x]
\end{gathered}
$$

Displacement $=$ speed x time.
In $u_{0}(x-c t) ; u_{0}(x)$ displaces $c t$.
$u_{0}(x-c t)$ satisfies migration equation at any initial population distribution $u_{0}(x)$ [113, 114].

### 3.3.1 An Improved Cockroach Swarm Optimization Model

CSO was originally designed with three components (Chase-swarming, dispersion and ruthless), it was extended with hunger component and an Improved Cockroach Swarm Optimization (ICSO) is proposed. This work introduces an improvement into the existing CSO algorithm [94]. This is done by introducing a hunger component, which is described by the PDE migration method, as shown above. Hunger behaviour is similar to find food behaviour described in [34]. After an interval of time, when a cockroach is hungry, it migrates from its comfortable shelter and friends to look for food [72, 34]. A cockroach migrates from its shelter to any available food source $x_{\text {food }}$ within the search space. In terms of search space, this prevents local optimum and enhances diversity of population. The PDE migration method is appropriate for describing the hunger behaviour of cockroaches where it is transported to food sources when hungry.

In our ICSO, find food behaviour described in [34] is remodelled to use the PDE migration method as derived in equation (3.3). This behaviour is only activated for each cockroach agent whenever the hunger threshold is reached. The hunger parameter is randomly generated in the uniform interval $[0,1]$ and compares with the hunger threshold. If this threshold is reached (i.e.hunger $==t_{\text {hunger }}$ ), then the cockroach agent is made to migrate to the other part of the solution space (in search of food) based on the PDE migration equation. This is illustrated as follows:

$$
\begin{gather*}
\text { if }\left(\text { hunger }==t_{\text {hunger }}\right) \\
x_{i}=x_{i}+\left(x_{i}-c t\right)+x_{\text {food }} \tag{3.3}
\end{gather*}
$$

where $x_{i}$ denotes cockroach position, $\left(x_{i}-c t\right)$ denotes cockroach migration from its present position, $c$ is a constant which controls migration speed, $t$ denotes time, $x_{\text {food }}$ denotes food locations, $t_{\text {hunger }}$ denotes hunger threshold and hunger is a random number $[0,1]$.

The computational steps for ICSO is shown in Algorithm4.

```
Algorithm 4 An Improved Cockroach Swarm Optimization Algorithm
    INPUT: Fitness function: \(f(x), x \in R^{D}\)
    set parameters and generate an initial population of cockroach
    set \(p_{g}=x_{1}\)
    for \(i=2\) to \(N\) do
        if \(f\left(x_{i}\right)<f\left(p_{g}\right)\) then
            \(p_{g}=x_{i}\)
        end if
    end for
    for \(t=1\) to \(T_{\text {max }}\) do
        for \(i=1\) to \(N\) do
            for \(j=1\) to \(N\) do
                if abs \(\left(x_{i}-x_{j}\right)<\operatorname{visual} ; f\left(x_{j}\right)<f\left(x_{i}\right)\) then
                \(p_{i}=x_{i}\)
                    end if
            end for
            if \(p_{i}==x_{i}\) then
                    \(x_{i}=w . x_{i}+\operatorname{ste} p * \operatorname{rand} *\left(p_{g}-x_{i}\right)\)
            else
                \(x_{i}=w . x_{i}+\operatorname{step} * \operatorname{rand} *\left(p_{i}-x_{i}\right)\)
            end if
            if \(f\left(x_{i}\right)<f\left(p_{g}\right)\) then
                \(p_{g}=x_{i}\)
            end if
        end for
        if Hunger \(==t_{\text {hunger }}\) then
            \(\left.x_{i}=x_{i}+\left(x_{i}-c t\right)+x_{f d}\right)\)
            hunger \(_{i}=0\)
            Increment hunger \({ }_{i}\) counters
        end if
        for \(i=1\) toN do
            \(x_{i}=x_{i}+\operatorname{rand}(1, D)\)
            if \(f\left(x_{i}\right)<f\left(p_{g}\right)\) then
                \(p_{g}=x_{i}\)
            end if
        end for
        \(k=\operatorname{randint}([1, N])\)
        \(x_{k}=p_{g} ;\)
    end for
    Check termination condition
```

### 3.4 A Dynamic Step-Size Adaptation with Simple Euler Method

A dynamic step-size adaptation roach infestation optimization (DSARIO) is proposed to improve the earlier work on the RIO algorithm [34]. This is achieved by introducing a simple Euler method of equation (3.4) into the original RIO model. The Euler method had been used earlier by Cai et al., to improve PSO algorithm performance [102] with promising results which motivated our usage. The introduction of the dynamic step-size adaptation of the Euler method is to help RIO to avoid local optimum, and maintain a balance between exploration and exploitation. A cockroach agent adjusts its velocity according to its performance. When it explores and locates a better region, it will make a local search around the current point, or use a global search pattern.

The Euler method is the simplest of the RungeKutta and numerical integration methods of ordinary differential equations (ODE) [115]. It can be used as the basis for constructing more complex methods [115].

The Euler method can be described by recalling function derivative definition

$$
\begin{equation*}
y^{\prime}(t)=\frac{y(t+h)-y(t)}{h} \tag{3.4}
\end{equation*}
$$

where $y$ is derivative of a function, $t$ is time and $h$ is the step-size.
According to Haven et al. [34], RIO find dark and friend behaviours, which is presented in section 2.5.1 and given as: If a cockroach comes within a detection radius of another cockroach agent, it will stop, socialize and share information of the darkest known location by setting local location $l$.

$$
\begin{equation*}
l_{i}=l_{j}=\arg _{k} \min \left\{F\left(p_{k}\right)\right\}, k=\{i, j\} \tag{3.5}
\end{equation*}
$$

where $\mathrm{i}, \mathrm{j}$ are the indices of the two socializing cockroaches and $p_{k}$ is the personal best known darkest location. Find darkest model of Equation is extended to include find friend behaviour [34]. Find dark and friend behaviour is:

$$
\begin{gather*}
v_{i}(t+1)=v_{i}(t)+c_{0} \cdot R_{1}\left(p_{i}(t)-x_{i}(t)\right)+C_{m a x} \cdot R_{2}\left(l_{i}(t)-x_{i}(t)\right)  \tag{3.6}\\
x_{i}(t+1)=x_{i}(t)+v_{i}(t+1) \tag{3.7}
\end{gather*}
$$

where $v_{i}(t)$ is the velocity of ith cockroach agent and $x_{i}(t)$ is the current location found by the ith agent at time $t, p_{i}(t)$ is the best location found by the ith agent and $l_{i}(t)$ is the best location of the entire swarm., $c_{0}, c_{\max }$ are cockroach parameter, $R_{1}$ and $R_{2}$ are vector of uniform random numbers, $\left(p_{i}(t)-x_{i}(t)\right)$ is a velocity change in the direction of the darkest known location of a cockroach in a local neighbourhood and $\left(l_{i}(t)-x_{i}(t)\right)$ is a velocity change in the direction of the darkest location
in the global search space.

Introducing Euler equation (3.4) on cockroach velocity $v_{i}(t)$ and position $x_{i}(t)$, and setting $h=1$, we have

$$
\begin{align*}
& \frac{d v_{i}}{d t}=v_{i}(t+1)-v_{i}(t)  \tag{3.8}\\
& \frac{d x_{i}}{d t}=x_{i}(t+1)-x_{i}(t) \tag{3.9}
\end{align*}
$$

$\psi_{1}=c_{0} \cdot R_{1}, \psi_{2}=c_{m a x} \cdot R_{2}$, and $\psi=\psi_{1}+\psi_{2}$ where $\psi_{1}, \psi_{2}$ and $\psi$ are constants

Substituting equations (3.6) and (3.7) in equations (3.8) and (3.9) we have

$$
\begin{gather*}
\frac{d v_{i}}{d t}=c_{0} \cdot R_{1}\left[p_{i}(t)-x_{i}(t)\right]+c_{\max } \cdot R_{2}\left[l_{i}(t)-x_{i}(t)\right]-v_{i}(t)  \tag{3.10}\\
\frac{d v_{i}}{d t}=\psi_{1}\left[p_{i}(t)-x_{i}(t)\right]+\psi_{2}\left[l_{i}(t)-x_{i}(t)\right]-v_{i}(t) \tag{3.11}
\end{gather*}
$$

By factorization,

$$
\begin{gather*}
\frac{d v_{i}}{d t}=-v_{i}(t)-x_{i}(t)\left[\psi_{1}+\psi_{2}\right]+\left(\psi_{1} p_{i}(t)+\psi_{2} l_{i}\right)  \tag{3.12}\\
\frac{d v_{i}}{d t}=-v_{i}-\psi x_{i}+\left(\psi_{1} p_{i}+\psi_{2} l_{i}\right) \tag{3.13}
\end{gather*}
$$

Likewise for

$$
\begin{gather*}
\frac{d x_{i}}{d t}=x_{i}(t+1)-x_{i}(t)  \tag{3.14}\\
\frac{d x_{i}}{d t}=x_{i}(t)+v_{i}(t+1)-x_{i}(t)  \tag{3.15}\\
\frac{d x_{i}}{d t}=x_{i}(t)+c_{0} \cdot R_{1}\left[p_{i}(t)-x_{i}(t)\right]+c_{m a x} \cdot R_{2}\left[l_{i}(t)-x_{i}(t)\right]-x_{i}(t)  \tag{3.16}\\
\frac{d x_{i}}{d t}=x_{i}(t)+\psi_{1}\left[p_{i}(t)-x_{i}(t)\right]+\psi_{2}\left[l_{i}(t)-x_{i}(t)\right]-x_{i}(t)  \tag{3.17}\\
\frac{d x_{i}}{d t}=-x_{i}\left[\psi_{1}+\psi_{2}\right]+\left(\psi_{1} p_{i}+\psi_{2} l_{i}\right)  \tag{3.18}\\
\frac{d x_{i}}{d t}=-\psi x_{i}+\left(\psi_{1} p_{i}+\psi_{2} l_{i}\right) \tag{3.19}
\end{gather*}
$$

With Euler step size $h$,

$$
\begin{equation*}
\frac{d v_{i}}{d t}=\frac{v_{i}(t+h)-v_{i}(t)}{h} \tag{3.20}
\end{equation*}
$$

$$
\begin{gather*}
\frac{d v_{i}}{d t}=-v_{i}-\psi x_{i}+\left(\psi_{1} p_{i}+\psi_{2} l_{i}\right)  \tag{3.21}\\
\frac{v_{i}(t+h)-v_{i}(t)}{h}=-v_{i}(t)-\psi x_{i}(t)+\left(\psi_{1} p_{i}(t)+\psi_{2} l_{i}(t)\right) \tag{3.22}
\end{gather*}
$$

Multiplying both sides by $h$, we have,

$$
\begin{gather*}
v_{i}(t+1)-v_{i}(t)=-h v_{i}(t)-h \psi x_{i}(t)+h\left(\psi_{1} p_{i}(t)+\psi_{2} l_{i}(t)\right)  \tag{3.23}\\
v_{i}(t+1)=v_{i}(t)-h v_{i}(t)-h \psi x_{i}(t)+h\left(\psi_{1} p_{i}(t)+\psi_{2} l_{i}(t)\right)  \tag{3.24}\\
v_{i}(t+1)=[1-h] v_{i}(t)-h \psi x_{i}(t)+h\left(\psi_{1} p_{i}(t)+\psi_{2} l_{i}(t)\right) \tag{3.25}
\end{gather*}
$$

Also, with Euler step size $h$ of equation 3.4.

$$
\begin{equation*}
\frac{d x_{i}}{d t}=\frac{x_{i}(t+h)-x_{i}(t)}{h} \tag{3.26}
\end{equation*}
$$

Since,

$$
\begin{gather*}
\frac{d x_{i}}{d t}=-\psi x_{i}(t)+\left(\psi_{1} p_{i}(t)+\psi_{2} l_{i}(t)\right)  \tag{3.27}\\
\frac{x_{i}(t+h)-x_{i}(t)}{h}=-\psi x_{i}(t)+\left(\psi_{1} p_{i}(t)+\psi_{2} l_{i}(t)\right) \tag{3.28}
\end{gather*}
$$

Multiplying both sides by $h$, we have,

$$
\begin{equation*}
x_{i}(t+1)-x_{i}(t)=-h \psi x_{i}(t)+h\left(\psi_{1} p_{i}(t)+\psi_{2} l_{i}(t)\right) \tag{3.29}
\end{equation*}
$$

i.e.,

$$
\begin{equation*}
x_{i}(t+1)=x_{i}(t)-h \psi x_{i}(t)+h\left(\psi_{1} p_{i}(t)+\psi_{2} l_{i}(t)\right) \tag{3.30}
\end{equation*}
$$

i.e.,

$$
\begin{equation*}
x_{i}(t+1)=[1-h] x_{i}(t)+h\left(\psi_{1} p_{i}(t)+\psi_{2} l_{i}(t)\right) \tag{3.31}
\end{equation*}
$$

Therefore, find dark and friend components is now:

$$
\begin{gather*}
v_{i}(t+1)=[1-h] v_{i}(t)-h \psi x_{i}(t)+h\left(\psi_{1} p_{i}(t)+\psi_{2} l_{i}(t)\right)  \tag{3.32}\\
x_{i}(t+1)=[1-h] x_{i}(t)+h\left(\psi_{1} p_{i}(t)+\psi_{2} l_{i}(t)\right) \tag{3.33}
\end{gather*}
$$

where $v_{i}$ denotes cockroach velocity, $x_{i}$ denotes cockroach position at time $t, p_{i}$ denotes local best position, $l_{i}$ denotes global best position, $\psi_{1}=c_{0} \cdot R_{1}, \psi_{2}=c_{\text {max }} \cdot R_{2}, \psi=\psi_{1}+\psi_{2}$ and $h$ is step-size. This new equation is introduced into RIO model as find dark and find friend behaviours, which lead
to DSARIO presented in the next subsection.

### 3.4.1 Dynamic Step-Size Adaptation Roach Infestation Optimization Model

The Euler method was applied to the original RIO model as shown in section 3.4 and we now have the proposed model DSARIO as:

1. Find Dark and find friend:

$$
\begin{gather*}
v_{i}(t+1)=[1-h] v_{i}(t)-h \psi x_{i}(t)+h\left(\psi_{1} p_{i}(t)+\psi_{2} l_{i}(t)\right)  \tag{3.34}\\
x_{i}(t+1)=[1-h] x_{i}(t)+h\left(\psi_{1} p_{i}(t)+\psi_{2} l_{i}(t)\right) \tag{3.35}
\end{gather*}
$$

where $v_{i}$ denotes cockroach velocity, $x_{i}$ denotes cockroach position at time $t$, $p_{i}$ denotes local best position, $l_{i}$ denotes global best position, $\psi_{1}=c_{0} \cdot R_{1}, \psi_{2}=c_{\max } \cdot R_{2}, \psi=\psi_{1}+\psi_{2}$ and $h$ is step-size.
2. Find food: Cockroaches look out for food source when hungry and being transported to a random food location $b$.

$$
\begin{equation*}
x_{i}=b \tag{3.36}
\end{equation*}
$$

For stability of Euler, Ascher and Petzold [116] recommended small step-size of $(h<0.2)$ to obtain accuracy per step, hence this is used in our implementation. Computational steps for DSARIO is illustrated in Algorithm 5 .

```
Algorithm 5 Dynamic Step-Size Adaptation Roach Infestation Optimization Algorithm
    INPUT: Fitness function: \(f(x), x \in R^{D}\)
    Initialize cockroach population, food location and set parameters
    for \(t=1\) to MaxIter do
        " \(M=\left[M_{i j}\right]=\left[\left\|\vec{x}_{j}-\vec{x}_{k}\right\|_{2}\right] d_{g}=\operatorname{median}\left\{M_{j k} \in M: 1 \leq j<k \leq N\right\}\) for \(i=1\) to \(N\) do
        if \(f\left(\vec{x}_{i}\right)<f\left(\vec{p}_{i}\right)\) then
            \(\vec{p}_{i}=\vec{x}_{i}\)
        end if
        Compute roach neighbours \(i\) as
        \(\{j\}=\left\{k: 1 \leq k \leq N, k \neq i, M_{i k}<d_{g}\right\}\)
        \(N_{i}=\) number of neighbour of \(|\{j\}|\)
        for \(q=1\) to \(N_{i}\) do
            if \(\operatorname{rand}[0,1]<A_{\text {min }}\{N, 3\}\) then
                \(\vec{l}_{i}=\vec{l}_{j}=\operatorname{argmin}_{k}\left\{f\left(\vec{p}_{k}\right)\right\}, k=\left\{i, j_{q}\right\}\)
            end if
        end for"
        if hunger \(_{i}<t_{\text {hunger }}\) then
            \(\vec{v}_{i}=[1-h] \vec{v}_{i}-h \psi \vec{x}_{i}+h\left(\psi_{1} \vec{p}_{i}+\psi_{2} \vec{l}_{i}\right)\)
            \(\vec{x}_{i}=(1-h \psi) \vec{x}_{i}+h\left(\psi_{1} \vec{p}_{i}+\psi_{2} \vec{l}_{i}\right)\)
        else
            \(\vec{x}_{i}=\vec{b}\)
            Randomly positioned food
            set hunger counter
        end if
        if Cockroach hungry then

### 3.5 Partial Differential Equation Method for Population Dispersion

At intervals of time a cockroach exhibits vigilance behaviour whenever light is shown in the dark shelter or the presence of a predator is noticed. The adult cockroaches, at the edge of the group, signal the young ones with body movements. Alarm pheromone will be emitted which results in the rapid dispersion of group members.

As described in section 3.3, PDE are used for formulation of problems, creation of models and expression of a wide variety of physical phenomena. In this section a PDE method for population dispersion which is designed to make overcrowding populations in a location, disperse over a wide area [113] is considered for describing the vigilance behaviour of cockroaches. The idea comes from the known PDE fundamental solution for dispersion presented by Kerckhove [113]. Population size $u$ is a dynamic quantity, its evolution is modelled as a function of time $t$ and location $x$.

The dispersion equation is given as

$$
\begin{equation*}
u_{t}=g u_{x x} \tag{3.37}
\end{equation*}
$$

where $u$ is the population size at time $t$ and location $x$ i.e., $u(t, x)$ and $u(0, x)=u_{0}(x)$ is the initial population distribution. $g$ denotes dispersion coefficient that controls dispersion speed.

The PDE for the population dispersion equation is expressed in [113] as:

$$
\begin{equation*}
\frac{\partial u}{\partial t}=g \frac{\partial^{2} u}{\partial x^{2}} ; g>0 \tag{3.38}
\end{equation*}
$$

$u(0, x)=f(x)$ is the Cauchy problem for this equation, where $f(x)$ is an arbitrary function. The general solution for dispersion equation by using the Fourier transform of the form

$$
\begin{equation*}
u(t, x)=\frac{1}{\sqrt{2 \pi}} \int_{-\infty}^{\infty} F(\zeta) e^{-g \zeta^{2} t} e^{i \xi x} d \zeta \tag{3.39}
\end{equation*}
$$

$F$ satisfy initial condition, it is an arbitrary function and given by transform of $f$, i.e

$$
\begin{equation*}
F(\zeta)=\frac{1}{\sqrt{2 \pi}} \int_{-\infty}^{\infty} f(x) e^{-i \zeta x} d x \tag{3.40}
\end{equation*}
$$

$f$ denotes intense source of dispersion, delta distribution is used to approximate the proceeding integral times source strength. A source strength normalized to 1 , gives:

$$
\begin{equation*}
F(\zeta)=\frac{1}{\sqrt{2 \pi}} \tag{3.41}
\end{equation*}
$$

give the resulting dispersion solution as

$$
\begin{equation*}
u(t, x)=\frac{1}{2 \pi} \int_{-\infty}^{\infty} e^{-g \zeta^{2} t} e^{i \zeta x} d \zeta \tag{3.42}
\end{equation*}
$$

This Gaussian integral is solved and we have

$$
\begin{equation*}
u(t, x)=\frac{1}{2 \sqrt{\pi g t}} \exp \left(-\frac{x^{2}}{4 g t}\right) \tag{3.43}
\end{equation*}
$$

i.e.,

$$
\begin{equation*}
u(t, x)=\frac{1}{\sqrt{(4 \pi g t)}} e^{\frac{-x^{2}}{4 g t}} \tag{3.44}
\end{equation*}
$$

$u(t, x)$ is the dispersion function that spread out in time t .

From equations (3.37) and (3.38)

$$
\begin{equation*}
g u_{x x}=g \frac{1}{\sqrt{( } 4 \pi g t)} \exp \left[\frac{-x^{2}}{4 g t}\right] \tag{3.45}
\end{equation*}
$$

We modelled vigilance behaviour as:

$$
\begin{equation*}
x_{i}^{n}=x_{i}+\left(\frac{g}{\sqrt{(4 \pi g t)}} \exp \left[\frac{-x_{i}^{2}}{4 g t}\right]\right) \tag{3.46}
\end{equation*}
$$

where $x_{i}^{n}$ denotes a cockroach's new position, $x_{i}$ denotes a cockroach's current position, $g$ denotes dispersion coefficient which is a constant that controls dispersion speed at time $t$. The larger the dispersion coefficient the faster the dispersion rate [113].

PDE for population dispersion, can make overcrowding populations in a location disperse over a wide area. It is appropriate for modelling the vigilance behaviour of cockroaches where cockroach populations disperse rapidly over a wider area in the search space. The vigilance behaviour is one of the components introduced into the existing RIO algorithm in section 3.6 .1 that leads to the construction of modified RIO. It is similar to the dispersion component of the original CSO algorithm.

### 3.6 Predator-prey with Crossover and Mutation Methods

A crossover method allows for the recombination of two solutions to get a better solution. A different solution is created in successive generations by combining materials from two individual solutions of the previous generation. The two solutions involved in the crossover operation are known as parent solutions and the resulting solutions are known as children solution [117, 118 , 119, 120]. The crossover process creates a point in the neighbourhood of the current point and achieves a local search around the current solution, it executes exploitation and leaves exploration for the mutation operator [120]. The mutation operator enhances population diversity by modifying chromosomes randomly. It is an exploration operator that recovers any diversity lost during the selection process and also explores solutions and prevents local convergence [120].

Predator-prey evolution method (PPEM) has been significantly used in optimization problems in several studies including [ $103,104,105,106,107,108,109,110,111]$. The idea of crossover and mutation for predator prey habit used in this thesis comes from Chowdhury et al. [104]. The basic concept of PPEM was suggested by Laumanns et al., [103], where an algorithm was described, that mimics the natural phenomena that a predator kills the weakest prey in its neighbourhood and the relatively strong prey that evolves from the next generation, then replaces the weak prey. New operators were introduced by Deb et al., [105, 110]. A dynamic spatial structure version of PPEM was proposed by Li [106]. Other versions were proposed [107, 108]. Chowdury et al., [104, 109] presented a modified predator-prey (MPP) algorithm where they made significant modifications to the pre-predator algorithm regarding selection procedure, predators movements and general dynamics for good convergence and solutions diversity, also reducing function evaluations number. MPP fundamental steps are outlined [109]. One of the significant features of MPP is evolution, which is described as crossover of the two strongest prey to evolve new solutions in a local neighbourhood containing a predator.

The blend crossover which was proposed [110], improved [111] and applied [104]. The blend crossover is described as follow:

$$
\begin{align*}
x_{i}^{(i, i+1)} & =\left(1-\gamma_{i}\right) x_{i}^{(1, t)}+\gamma_{i} x_{i}^{(2, t)}  \tag{3.47}\\
\gamma_{i} & =(1+2 \alpha) U_{i}-\alpha \tag{3.48}
\end{align*}
$$

where $\gamma_{i}$ is a cross-over operator, $x_{i}^{(1, t)}$ and $x_{i}^{(2, t)}$ are parent solutions, $x_{i}^{(i, i+1)}$ is a child solution of parent $x_{i}^{(1, t)}$ and $x_{i}^{(2, t)}, \alpha$ is a constants value 0.5 as suggested by Deb [111], $U_{i} \in U(0,1)$ is a uniform random numbers between zero and one that allows uniformly random distribution of crossover operator values in each iteration.

Crossover offspring prey is subjected to non-uniform mutation that was introduced [121] and modified [109]. This is to allow adjustment in the extent of mutation dynamically.

$$
\begin{gather*}
\beta=10^{-\left(t / T_{\max }\right)}  \tag{3.49}\\
y_{i}^{(i, i+1)}=x_{i}^{(i, i+1)}+\tau \beta\left(x_{i}^{U P}-x_{i}^{L W}\right)\left[1-r_{i}^{\left(1-\left(t / T_{\max }\right)\right)^{b}}\right] \tag{3.50}
\end{gather*}
$$

$y_{i}^{(i, i+1)}$ is a child produced from parent solution $x_{i}^{(i, i+1)}, \tau$ is a boolean value -1 or 1 , with fifty percent probability each, $r_{i}$ is randomly generated [0,1], ( $x_{i}^{U P}$ and $\left.x_{i}^{L W}\right)$ denotes variable $i$ upper and lower limits. $b$ is a constant of value 1.5 as suggested by Chowdhury et al. [109], $b$ is a scaling parameter, $t$ and $T_{\text {max }}$ represent iterations number and maximum iterations respectively.

In this work, we postulate that the predator-prey with crossover and mutation methods approach is suitable for describing cannibalism behaviour of cockroaches. The cannibalism behaviour is described thus: Cockroaches exhibit the predator-prey habit of eating one another, when a cockroach is hungry and there is no food in the neighbourhood, the strong cockroach eats the weak ones [35, 72]. The cannibalism habit of the cockroach is modelled as a situation whereby a strong cockroach called the predator, eats the weakest cockroach called the prey, in its neighbourhood. The generation of new solutions in a local neighbourhood containing a predator, is instigated by crossover of the two local prey and mutation is performed on the crossover child prey.

The evolution method of MPP [104] is adopted for modelling cockroach cannibalism behaviour in this work. This method was investigated first in RIO algorithm to describe a cannibalism habits of cockroaches that was included as one of the new components to the original RIO in this work. We conducted experiments to evaluate the effect of PPEM on RIO and found it efficient, as revealed by the results of the experiment. Motivation from the results led to investigation of PPEM also in CSO algorithm. The ruthless component of the CSO algorithm was modified using the PPEM. Simulation studies were carried out using 70 global optimization test problems and comparisons were done experimentally and statistically with similar algorithms.

Vigilance and cannibalism behaviours of cockroaches were modelled in this work, using the methods described above as shown in section 3.6.1.

### 3.6.1 Modified Roach Infestation Optimization Model

Havens et al., presented RIO as a PSO-adapted algorithm with a slack cockroach behaviour model [34]. The RIO model as presented in section 2.5.1 has three essential components namely find dark, find friend and find food. In this work, we extended the original RIO model by reconstructing find dark and friend components and also added vigilance and cannibalism components,
to give the modified roach infestation optimization (MRIO). An MRIO algorithm that is tied to cockroach social behaviours is proposed in this work as an improvement over the original RIO algorithm. MRIO is constructed with the following components:

1. Find dark and find friends: Cockroaches always seek dark shelters and also prefer to travel in the dark to locate and socialize with their friends in dark places. Cockroaches usually locate their friends in dark shelters, the darker a location the more cockroaches are found there; darkness corresponds to the fitness value of the fitness function $f(x) \in \mathbb{R}^{D}$. The level of darkness at a location $p_{k} \in \mathbb{R}^{D}$ is directly proportional to the value of the fitness function at that location $f\left(p_{k}\right)$.

We redesign RIO find dark and friend of section 2.5 .1 and present the new model as:

$$
x_{i}^{n}=\left\{\begin{array}{c}
\lambda\left(x_{i}+\psi_{1}\left(p_{i}-x_{i}\right)\right)  \tag{3.51}\\
\lambda\left(x_{i}+\psi_{2}\left(l_{i}-x_{i}\right)\right)
\end{array}\right.
$$

where $\lambda$ denotes the constrained factor that prevents swarm explosion, maintains swarm stability and controls cockroach movement from its current position towards its new position; $x_{i}$ denotes the cockroach's current position; $x_{i}^{n}$ denotes the cockroach's new position; $\psi_{1}=c_{0} R_{1}$ is cockroach's cognitive factor for locating a personal dark position; $\psi_{2}=c_{\max } R_{2}$ is the cockroach's social factor for locating global dark position; $c_{0}$ and $c_{\max }$ are constants while $R_{1} \in U(0,1)$ and $R_{2} \in U(0,1)$ are random sequences of numbers between 0 and 1 that effect stochastic nature of the algorithm; $p_{i}$ denotes the cockroach's darkest known position in a local neighbourhood; $\left(p_{i}-x_{i}\right)$ denotes cockroach movement from current position towards the darkest known position, $l_{i}$ denotes the global dark position in the entire given search region where other cockroaches can be found. $\left(l_{i}-x_{i}\right)$ denotes the cockroach's movement from its current position towards the darkest position.
2. Find food: Find food behaviour as presented in section 2.5.1][34]: At intervals of time when a cockroach agent $i$ becomes hungry, it searches for food and is taken to a random food position $b$.

$$
\begin{equation*}
x_{i}=b \tag{3.52}
\end{equation*}
$$

3. Vigilance behaviour: At intervals of time, in the aggregation of cockroaches, when the presence of a predator is noticed or light is shown in their shelter, the older cockroaches warn the younger cockroaches with body movement and emit dispersion alarm pheromone [72]
which make cockroaches disperse rapidly over a wider area in the search space. Vigilance behaviour as presented in section 3.5 is given as:

$$
\begin{equation*}
x_{i}^{n}=x_{i}+\left(\frac{g}{\sqrt{(4 \pi g t)}} \exp \left[\frac{-x_{i}^{2}}{4 g t}\right]\right) \tag{3.53}
\end{equation*}
$$

where $x_{i}^{n}$ denotes the cockroach's new position, $x_{i}$ denotes a cockroach's current position, $g$ denotes dispersion coefficient which is a constant that controls dispersion speed at time $t$.
4. Cannibalism behaviour: Very rarely, when hungry and there is no food in the neighbourhood, a cockroach will exhibit cannibalism by eating another [72]. A strong cockroach will eat up the weak ones in its neighbourhood. Chowdhury et al. [104], present a predator-prey method. We adopted the method for cannibalism behaviour. The cannibalism habit represents a situation whereby strong cockroaches (predator), eat the weakest cockroaches (prey), in its neighbourhood and emerge as good solutions or the next generation of prey. The generation of new solutions in a local neighbourhood containing a predator- Strong cockroach, is instigated by crossover of the strongest two local cockroaches-preys. Mutation is performed on the cross-over child prey and the resulting solution is taken as the best solution. Cannibalism behaviour as presented in section 3.6 is given as:

$$
\begin{gather*}
x_{i}^{(i, i+1)}=\left(1-\gamma_{i}\right) x_{i}^{(1, t)}+\gamma_{i} x_{i}^{(2, t)}  \tag{3.54}\\
\gamma_{i}=(1+2 \alpha) U_{i}-\alpha  \tag{3.55}\\
\beta=10^{-\left(t / T_{\max }\right)}  \tag{3.56}\\
y_{i}^{(i, i+1)}=x_{i}^{(i, i+1)}+\tau \beta\left(x_{i}^{U P}-x_{i}^{L W}\right)\left[1-r_{i}^{\left(1-\left(t / T_{\max }\right)\right)^{b}}\right] \tag{3.57}
\end{gather*}
$$

where $x_{i}^{(1, t)}$ and $x_{i}^{(2, t)}$ are parent solutions from cockroach population, $x_{i}^{(i, i+1)}$ is a child solution of parent $x_{i}^{(1, t)}$ and $x_{i}^{(2, t)}, \alpha$ is a constants of value $0.5, U_{i} \in U(0,1) . y_{i}^{(i, i+1)}$ is a child produced from parent solution $x_{i}^{(i, i+1)}, \tau$ is a boolean of -1 or 1 value with $50 \%$ probability, $r_{i}$ is rand[0,1], $\left(x_{i}^{U P}\right.$ and $\left.x_{i}^{L W}\right)$ denotes variable $i$ upper and lower limits. $b$ is a scaling parameter, $t$ and $T_{\max }$ represent iterations number and maximum iterations respectively. $i$ denotes variable (cockroach) in cockroach population $x_{i}$. The child $y_{i}^{(i, i+1)}$ is considered as
the optimum solution in each iteration.
The MRIO computational steps are given as:

1. Initialise cockroach swarm with uniformly distributed random numbers and set all parameters with values.
2. Locate best position using equations (2.8).
3. Perform find dark and friends behaviour using equation (3.51).
4. Perform find food behaviour using equation (3.52).
5. Perform vigilance behaviour using equation (3.53).
6. Perform cannibalism behaviour using equations (3.54), (3.55) and (3.57)
7. Update global best position.
8. Repeat the loop until stopping criteria is reached.

### 3.7 Adaptive Cockroach Swarm Model

Establishing a balance of local and global search of a search region, by the crossover and mutation approach is very adequate for complex optimization problems to which classical methods cannot provide solutions [120]. In addition to the establishment of balance of exploration and exploitation, it is good to ensure that such balance is self-adaptive. That is, the distribution of the offspring depends on that of parents [120]. Through self-adaptation, close parents will generate close offspring and vice versa [120]. Recent studies on the blend crossover $(B L X-\alpha)$ [104, 109, [110, 111, 120] have shown good performance of the crossover operator that generates individuals in the exploration zone. The blend crossover operator maintains diversity, prevents the premature convergence to inner points of the search space and generates offspring in the exploration and exploitation zones in the correct proportion. In blend crossover $(B L X-\alpha)$ there is the same probability of generating an offspring between the parents, and in an area close to the parents whose amplitude is modulated by the $\alpha$ parameter[120].
$x_{i}^{(1, t)}$ and $x_{i}^{(2, t)}$ are parent solutions [111].
Assuming $x_{i}^{(1, t)}<x_{i}^{(2, t)}$
The $B L X-\alpha$ selects a solution at random in this range:

$$
\left[x_{i}^{(1, t)}-\alpha\left(x_{i}^{(2, t)}-x_{i}^{(1, t)}, x_{i}^{(2, t)}+\alpha\left(x_{i}^{(2, t)}-x_{i}^{(1, t)}\right)\right)\right]
$$

$U_{i} \in(0,1)$ is the random number between 0 and 1
The child is given as:

$$
x_{i}^{(i, i+1)}=\left(1-\gamma_{i}\right) x_{i}^{(1, t)}+\gamma_{i} x_{i}^{(2, t)}
$$

where $\gamma_{i}=(1+2 \alpha) U_{i}-\alpha$.
Blend crossover $B L X-\alpha$ has an interesting feature for search algorithms to exhibit selfadaptation which causes populations to either diverge or converge for better regions in the search region [111, 120].

In this work, blend crossover $(B L X-\alpha)$ is adopted, being inspired by the results from previous studies which include [104, 109, 110, 111, 120]. We introduce blend crossover PPEM into our CSO algorithm and proposed an adaptive CSO (ACSO). Blend crossover is introduced into CSO to control balance between exploration and exploitation; and improve convergence speed by self-adaptive component. These features are appreciated in any search algorithm for preventing premature convergence and improving local fine-tuning [120]. This technique has been shown effective in many studies as already indicated in this section and has been equally shown in our study on MRIO presented in section 3.6.1 where we constructed one of the components with PPEM.

In the study of ACSO, the ruthless behaviour component of the CSO algorithm which was designed in the original CSO algorithm is modified using PPEM. The ruthless component of the original CSO [35] is described as the current best cockroach replacing the one that is picked randomly at intervals of time. The strong one eats the weak one.

$$
\begin{equation*}
x_{k}=p_{g} \tag{3.58}
\end{equation*}
$$

where $k$ is a random integer within $[1, \mathrm{~N}], p_{g}$ is the global best cockroach.
It is obvious from equation (3.58) that there is the possibility of population collapse as a result of continuous ruthlessness when strong cockroaches keep eating the weak ones. Also if the ruthlessness is high, strong cockroaches may possibly eat another cockroach, which might have been a good solution. To avoid the likelihood of population collapse, we engage the PPEM presented in section 3.6 to modified the ruthless component. When a weak cockroach (prey) is eaten by a strong cockroach (predator), another relatively strong cockroach is created through evolution of the PPEM approach to replace the cockroach prey. By this approach, the population is preserved. The ruthless component is now modelled using PPEM similar to the cannibalism component of MRIO algorithm. ACSO extended our proposed ICSO presented in section 3.3.1 with the PPEM process; the computational steps for ACSO algorithm is illustrated in Algorithm 6 .

```

        end for
        Update global optimum
        if \(f\left(x_{i}\right)<f\left(p_{g}\right)\) then
            \(p_{g}=x_{i}\)
        end if
    end while
    Check termination condition

\subsection*{3.8 Discretization Using Sigmoid Function}

Most swarm intelligence algorithms were traditionally designed to provide solutions to continuous optimization problems. Nevertheless they can be adapted to discrete optimization such as binary and combinatorial by discretization of the continuous space [122]. This can be accomplished by transforming continuous values into a limited number of possible states.

The sigmoid function can be used to transform a continuous space into a binary one [54]. The combination of sigmoid function with an additional operator can be used for the transformation of continuous space into multi valued discrete space as shown in these studies [55, 56, 57]. The transformation is applied to each dimension of the solution vector forcing each element to be a binary digit or other digits greater than 2 [122]. The resulting change in position is defined in equations (2.1) and (2.3) of section 2.3.5 for binary and multi-valued discrete spaces respectively.

The idea of using sigmoid function comes from studies on binary and discrete PSO which include [54, 55, 56, 57]. See section 2.3.5]for further details on sigmoid function and discretization.

\subsection*{3.8.1 Discrete Space Cockroach Swarm Models}

Our study on a multi-valued discrete space cockroach swarm optimization (DCSO) algorithm was inspired by the previous studies on binary and discrete PSO which include [54, 55, 56, 57], where PSO algorithms that were traditionally designed for continuous optimization problems were translated into binary discrete valued space. DCSO was specifically inspired by the study of Osadciw and Veeramachaneni who presented a multi-valued discrete PSO [55] where they use sigmoid with additional operators for logistic transformation of particle states (See section 2.3.5). We adopted similar techniques for DCSO by extending a CSO algorithm that was originally designed for continuous valued space to construct a multi-valued discrete space algorithm. DCSO can search in discrete space \([0, B-1]\); where \(B\) denotes any number system such as binary, ternary and quaternary. DCSO searches from one state to another, for instance in binary space, it searches between states ( 0 and 1 ); ternary ( 0,1 , and 2 ); quaternary ( \(0,1,2\) and 3 ). Cockroach position is translated into number between \([0, B-1]\). An operator \(\mu\) is introduced in this study for the enhancement of convergence of the DSCO algorithm, optimal results were obtained in each experiment when \(\mu\) is set to a random number between 0.1 and 0.2 .

A sigmoid \(S_{i}=\frac{B}{1+e^{-x_{i}}}\) with \((B-1) \mu\) is used to generate solution that is rounded to the nearest discrete variable.
\[
x_{i}=\operatorname{round}\left((B-1) \mu+S_{i}\right)
\]

Cockroach position is updated as:
\[
x_{i}=\left\{\begin{array}{rrr}
B-1, & & \text { if }  \tag{3.59}\\
0, & x_{i}>B-1 \\
0, & \text { if } x_{i}<0
\end{array}\right.
\]
where \(x_{i}\) is current position, \(B\) is base number considered and \(\mu\) is an operator which enhances the performance of the algorithm. Cockroach positions are now discrete values between 0 and \(B-1\). There is a possibility of selecting a number between \([0, B-1]\).
DCSO algorithm is shown in Algorithm 7 and its computational steps are given as:
1. Initialize cockroach swarm with uniform distributed random numbers in the range \([0, B-1]\) and set all parameters with values.
2. Find best position using equations (2.13) and (2.14).
3. Exhibit chase-swarming behaviour using equation (3.1).
4. Exhibit dispersion behavior using equation (2.15).
4. Exhibit hunger behavior using equation (3.3).
5. Exhibit ruthless behavior
6. Limit cockroach agent \(i\) magnitude with constant \(x_{\max }\) if \(x_{i}>x_{\max }\) then
\(x_{i}=x_{\text {max }}\)
elseif \(x_{i}<-\left(x_{\max }\right)\) then
\(x_{i}=-\left(x_{\max }\right)\)
7. Update cockroach position using sigmoid function to transform position probabilistically.
\(S_{i}=\frac{B}{1+e^{-x_{i}}}\)
\(x_{i}=\operatorname{round}\left((B-1) \mu+S_{i}\right)\)
if \(x_{i}>B-1\) then \(x_{i}=B-1\)
and if \(x_{i}<0\) then \(x_{i}=0\).
8. Repeat the loop until stopping criteria is reached.

DCSO was evaluated using benchmark test functions and also on 53 TSP instances. The results of the test are shown in sections 5.7 and 5.8 respectively.
```

Algorithm 7 Discrete Space Cockroach Swarm Optimization
INPUT: Fitness function: $x_{i} \in\{0,(B-1)\}^{D}, f:\{0,(B-1)\}^{D} \rightarrow \mathbb{R}^{D}$
set parameters and generate an initial population of cockroach
set $p_{g}=x_{1}$

\subsection*{3.8.2 DCSO for Travelling Salesman Problem}

DCSO was applied to TSP instances in this work. DCSO is improved for solving TSP by the incorporation of the nearest neighbour (NN) algorithm and iterated 2-opt search method. Improvement is done upon each tour by the employment of 2-opt heuristics and the best result is chosen. The initial tour is constructed with the local search method and 2-opt technique was used for interchanging edges. Nearest neighbour algorithm and iterated 2-opt search method are described in sections 3.8.3 and 3.8.4 respectively.

\subsection*{3.8.3 Tour Construction Method}

The nearest neighbour ( NN ) method is used in this study to construct the initial tour. NN is a simple and well known method for TSP; the method begins with a tour that is made up of randomly chosen city and subsequently added unvisited city to the last city [71]. The algorithm continues until all the cities are on the tour. Computational steps of NN on TSP is given as:
1. Begin with current city (randomly choose a city and set it as the current city)
2. Detect the shortest edge connecting current city and an unvisited city V.
3. Set current city to V and mark it as visited.
4. If all the cities in domain are visited, then terminate, otherwise return to step 2.

\subsection*{3.8.4 Tour Improvement Method}

Tour improvement methods are simple local search heuristics for improving initial tour [71]. We use 2-opt method in this paper to improve the initial tour; the tour improved iteratively by moving from one tour to its best neighbour until no further possible improvement is reached. 2-opt searching method is a well-known method for solving TSP; it is mainly used for improving solution. The 2-opt technique check if the exchange of an edge with another edge gives a minimum tour and the process continues until there is no more possible improvements to be done [66, 71]. The 2-opt method consists of three steps:

1 Take two pairs of nodes \((\mathrm{P}, \mathrm{Q})\) and \((\mathrm{R}, \mathrm{S})\) respectively from a tour and check if the distance PQRS is longer than PSQR.

2 If true, swap P and R i.e reversing the tour between the two nodes.
3 Continue with the improvement process by retuning to step 1 , otherwise stop if no improvement is possible.

\subsection*{3.8.5 DCSO-TSP Computational Steps}

In a TSP of m-ordered, cockroach's position in cockroach population is denoted as \(X_{i}=\left(x_{i 1}, x_{i 1} \ldots x_{i m}\right)\) which represents the travelling circle of \(x_{i 1} \rightarrow x_{i 2} \rightarrow \ldots x_{i m} \rightarrow x_{i 1}\)

The computational steps of the proposed DCSO algorithm for TSP is described as follows:
1 Initialize a cockroach swarm with uniform distributed random numbers in the range \([0, B-\) 1], make a tour construction using the nearest neighbour method, evaluate each population member (calculate total distance), initialize each cockroach position: Set \(p_{i}\) as the initial position, search for the best route \(p_{g}\) in the population.

2 Apply the DCSO process to each cockroach, compute new position and update new position.
3 Improve the position of cockroaches using 2-opt method.
4 Check termination condition. If satisfied, stop the algorithm, otherwise return to step 2.

\section*{Chapter 4}

\section*{Experimental Design}

\subsection*{4.1 Implementation Platform}

All algorithms proposed as presented in Chapter 3 were implemented in MATLAB 7.14 (R2012a) environment on HP ProBook 4530 with a Windows 7 operating system; containing 2.30 GHz processor and 4.00 GB of RAM. The computer system configuration is shown in Table 4.1.

Table 4.1: Computer System Configuration
\begin{tabular}{ll}
\hline System & HP ProBook 4530 \\
CPU & 2.30 GHz \\
RAM & 4.00 GB \\
Operating System & Windows 7 \\
Implementation Platform & MATLAB 7.14 (R2012a) \\
\hline
\end{tabular}

\subsection*{4.2 Parameter Selection}

The parameters of RBA include: cockroach population size \(N\), the maximum iteration \(T_{\max }, t\) is the number of iteration, hunger interval \(t_{\text {hunger }}\), Cockroach largest step Step \(=2\). Table 4.2 depicts standard parameter settings that have been used successfully for RIO and CSO in the literature [34, 35, 94] and presented in Chapter 2 . Additional parameters used by improved RBAs as presented in Chapter 3 for SCCSO, ICSO, DSARIO, MRIO, ACSO and DCSO are: \(\xi=\operatorname{rand}[0,1]\) constrained factor, \(c=5\) constant that controls migration speed, \(t=5\) migration time, hunger threshold 0.5 , Euler step-size \(h=0.1, g=20\) dispersion coefficient, \(\alpha=0.5\) a constant which is the adaptive coefficient, \(\tau\) is boolean with value \(-1,1\) with the probability of \(0.5, b=1.5\) is a constant which is a scaling parameter, \(U_{i}=U(0,1), B\) number base (binary, ternary, etc) and \(\mu=\operatorname{rand}[0.1,0.2]\).

Table 4.2: Experiment Parameters
\begin{tabular}{ll}
\hline \hline & Description \\
\hline N & Swarm size \\
\(T_{\text {max }}\) & Maximum iterations \\
\(C_{0}=0.7, C_{\max }=1.43\) & Cockroach parameters \\
\(A_{1}=0.49, A_{2}=0.63, A_{3}=0.65\) & Probabilities of \\
& cockroaches socializing with one another \\
\(t_{\text {hunger }}=100\) & hunger interval \\
Step \(=2\) & Cockroach largest step \\
\(w=0.618\) & Inertial weight \\
visual \(=1\) & Cockroach visual scope \\
\hline
\end{tabular}

\subsection*{4.3 Statistical Analysis Tools}

The statistical analysis tools used for analysis of data in this work are Kruskal-Wallis test, a Analysis of variance (ANOVA) test, Jonckheere-Terpstra test and Mann-Whitney U-test as reported in Chapter 5. Tools such as the Kruskal-Wallis test, a Analysis of variance (ANOVA) test and Jonckheere-Terpstra test statistic are used for data that has two or more independent groups. The Mann-Whitney U-test statistic tool is used for data that have only two independent groups.

The statistical evidence derived from any of the statistical tools determines the acceptance or rejection of the Null Hypothesis that proposes that no statistical significance exists in a set of given observations. The calculated p-value is the probability of obtaining either the observed difference or a more extreme value of the difference between the two groups, it is used as a basis for either accepting or rejecting the Null Hypothesis. If the p-value is less than a threshold value of 0.05 , we reject the Null Hypothesis and the result is considered significant. On the other hand, if the p-value is greater than 0.05, we accept the Null Hypothesis.

\subsection*{4.4 Global Optimization Test Problems}

Global optimization test functions are used for validating and comparing the performance of optimization algorithms. In this thesis, we tested the reliability, efficiency and validation of the improved RBA with test functions of diverse properties in terms of modality, separability and valley landscape.

The validation of the performance of the developed RBA variants over a set of test functions presented in Appendix A were carried out in this work. The test function in Appendix A have been used by many researchers and reported in the literature. The developed RBA variants were deployed for varying global optimization problems and the obtained results compared empirically
and statistically with the exiting algorithms.
Furthermore, discrete cockroach swarm optimization was tested on TSP using 53 instances of TSP from TSP library [123].

\subsection*{4.5 Performance Evaluation Criteria}

The performance of evolutionary algorithms can be evaluated using some major criteria such as convergence, speed, robustness and success performance [124, 125]. Convergence measure determines how accurately an algorithm converges to the desired solution through scientific means. We use equation (4.1) to test the convergence of all the algorithms in this work; the equation checks if the difference between the numerical approximation of each algorithm and the global optimum of a problem satisfies the given condition. In all our experiments, a run is terminated when the algorithm satisfies the condition of equation (4.1).
\[
\begin{equation*}
\left|f\left(x^{*}\right)-f_{\text {min }}\right| \leq \varepsilon \tag{4.1}
\end{equation*}
\]
where \(f\left(x^{*}\right)\) is best among all the best solutions found, \(f_{\text {min }}\) is the desired optimal solution and \(\varepsilon=10^{-4}\).

The speed of an algorithm is determined by the number of function evaluations which are machine independent [126, 125, 127, 128]. The mean of function evaluation (MFE) was computed in our experiments. We also measure the speed of algorithms run on the same machine, using run-time which is computed in seconds during experiments.

The robustness of an algorithm is measured by the wide range of problems the algorithm can solve. The improved algorithms presented in this work were tested on large numbers of problems shown in Appendix A. Each experiments runs for a specified number of times.

The following statistical measures were obtained from our experiments using the above mentioned criteria.
1. Minimum Optimum (MinOpt): This is the best of all best solutions found by each algorithm on a test problem at the end of the experiment. It is defined as
\[
\begin{equation*}
\operatorname{MinOpt}=\min \left\{f_{\min 1}, f_{\min 2}, \ldots, f_{\operatorname{minn}}\right\} \tag{4.2}
\end{equation*}
\]
where n denotes number of runs.
2. Mean optimal (MeanOpt): This is the average fitness value of all the best solutions found by
each algorithm on a test problem in an experiment. MeanOpt is defined by:
\[
\begin{equation*}
\text { MeanOpt }=\frac{1}{n} \sum_{i=1}^{n} f_{\min i} \tag{4.3}
\end{equation*}
\]
where n denotes number of runs.
3. MFE of all the function evaluations of the best solutions found by each algorithm on a test problem per experiment. MFE can be described as:
\[
\begin{equation*}
M F E=\frac{1}{n} \sum_{i=1}^{n} F E_{i} \tag{4.4}
\end{equation*}
\]
4. Standard Deviations: The measure of dispersion of the best solutions of mean optimal was computed for each algorithm per problem.
5. Success Rate: A run is considered successful if an algorithm is able to find the optimal solution for a given problem [124, 125, 129]. The success of an algorithm is determined by the number of successful runs out of the total number of runs. Success rate (SRT) is computed using:
\[
\begin{equation*}
S R T=\frac{S R}{T R} \times 100 \tag{4.5}
\end{equation*}
\]
where \(S R\) denotes number of successful runs and \(T R\) denotes number of total runs.
6. Success Performance: Success performance (SP) can be used to estimate the number of function evaluations needed for an algorithm to successfully solve a problem. SP is computed using equation (4.6) [125, 129, 130].
\[
\begin{equation*}
S P=\operatorname{Mean}(F E s) \times \frac{T R}{S R} \tag{4.6}
\end{equation*}
\]
where \(F E s\) is the function evaluations of successful runs, \(T R\) denotes number of total runs and \(S R\) denotes number of successful runs. We compute the normalised SP (nSP) by dividing an algorithm \(S P\) by the \(S P\) of the best performing algorithm \(\left(S P_{\text {best }}\right)\) on a given problem [125].
7. Test statistics of Kruskal-Wallis, ANOVA, Jonckheere-Terpstra, Mann-Whitney U-test were used to determine the significant difference of the improved algorithms over the existing ones. See section 4.3.
8. Error estimate (Error): Numerical error estimate used for measuring the accuracy of the numerical approximation of solutions found, to the true value of global minimum is Error.
\[
\text { Error }=\left\{\begin{array}{cc}
\left|f\left(x^{*}\right)-f_{\text {min }}\right|, & \text { if }  \tag{4.7}\\
\frac{\mid f\left(x^{*}\right)=0}{f\left(x^{*}\right)-f_{\text {min }} \mid} & \text { otherwise }
\end{array}\right.
\]

\section*{Chapter 5}

\section*{Experimental Settings and Results}

\subsection*{5.1 Introduction}

The improved RBA variants presented in Chapter 3 were simulated using the experimental designs shown in Chapter 4 and the respective experimental settings shown in this chapter. The empirical results of each RBA variant which were statistically analysed and compared with related existing algorithms are presented.

\subsection*{5.2 Stochastic Constriction Cockroach Swarm Optimization for Multidimensional Space Function Problems}

A SCCSO model described in section 3.2 .1 was implemented and evaluated on global optimization problems. A series of experiments were conducted in two stages to prove the effect of SCF in the performance of SCCSO on a set of standard benchmark multi-dimension test function problems presented in Table 16 of Appendix A. Each experiment runs 20 times with a maximum iteration of 1000 , using cockroach swarm size 50 . For each benchmark, global minimum values were computed in each experiment; the best, average and standard deviation of the optimal values were recorded.

In stage I of the experiments, the performance of SCCSO was compared with that of existing CSO and Modified Cockroach Swarm Optimization (MSCO) algorithms of [35, 94] for dimensions 10, 20, 30 and 40. Success rates and computation time in seconds were recorded. Tables \(5.1,5.2\), 5.3. 5.4 show the results of stage I experiment while Tables 5.5, 5.6, 5.7 depicts the comparison best, average and standard deviation results respectively. Tables 5.8 and 5.9 show the comparison success rate and execution time respectively.

Stage II experiments show the performance of SCCSO for dimensions 50, 100, 500, 1000,

2000 and 3000 in Tables 5.10, 5.11, 5.12, 5.13 5.14 and 5.15 respectively. The performance of SCCSO was compared with that of a line search restart (LSRS) technique which had been proved in literature for evaluating high dimension test function problems [131]; Table 5.17] shows the comparison average performance of LSRS and SCCSO.

The test statistic of ANOVA was conducted to determine the significant difference between the average performance of SCCSO and LSRS. The results of the test statistic are in table 5.17 and the graphical representation is depicted in Figure 5.1. No. 1 and 2 on x-axis of Figure 5.1 denote LSRS and SCCSO algorithms respectively. The result of the test statistics shows that there is no significant difference between SCCSO and LSRS algorithms.

The effects of the stochastic constriction were revealed in our experiments; SCCSO was shown to have better convergence and speed than the existing CSO and MSCO for dimensions 10,20,30 and 40. SCCSO showed similar performance to LSRS for problems of dimensions 50, 100, 500, 1000 and 2000. SCCSO was tested further for dimensions 3000, and without modifying the algorithm, it can evaluate higher number of variables above 3000 dimensions. The comparisons results of SCCSO with the existing CSO and MCSO proved its superiority, also the comparison of SCCSO with LSRS proved its ability to compete with known global optimization technique.

Figure 5.1: ANOVA test for LSRS and SCCSO.

\subsection*{5.3 An Improved Cockroach Swarm Optimization}

In section 3.3.1, the proposed ICSO model is shown. Simulation studies were carried out on the proposed algorithm and its performance was evaluated on 23 global optimization benchmark problems presented in Table 17 of Appendix A. A series of experiments were conducted to compare the performance of ICSO with that of the existing cockroach algorithms namely: Roach infestation optimization (RIO), Hungry roach infestation optimization (HRIO), CSO and MCSO. The results of the experiments are shown in Tables 5.18, 5.19 and 5.20 .

The comparison results of the best, average and standard deviation performance are shown in Tables 5.22, 5.21, 5.23 while the comparison results of the success performance and execution time in seconds utilized by each algorithm to solve the respective benchmarks, are shown in Tables 5.24 and 5.25 .

The test statistic of Jonckheere-Terpstra (J-T) was conducted to determine if the performance of ICSO algorithm is significantly different from the comparison algorithms. The test statistic results in Table 5.26 show that the proposed algorithm performs better than others. The J-T test statistic P-value (Asymp. Sig.) was computed to be 0.001 in Table 5.26. The P-Value is less than the threshold value 0.05 ; therefore, there is a significant difference in performance of ICSO and that of RIO, HRIO, CSO and MCSO.

The magnitude of the observed effect of the significant difference is measured by computing the effect size. The effect size \(r,(1>r<0)\) of the significant difference of J-T test was calculated as: [114]
\(r=\frac{Z}{\sqrt{N}}\),
where Z is the standard data of \(\mathrm{J}-\mathrm{T}\) statistic as shown in Table \(5.26, \mathrm{~N}\) is the total number of samples, \(N=114\).
\(Z=\frac{x-\mu}{\sigma}\),
x denotes J-T Statistic observed, \(\mu\) denotes J-T statistic mean and \(\sigma\) denoted the standard deviation of J-T statistic.
\(Z=\frac{1952-2599}{199.355}=-3.245\),
\(r=\frac{-3.245}{\sqrt{114}}=-0.3\).
Absolute value of \(|Z|\) is the distance between the observed data and the mean in units of standard deviation ( \(Z\) is negative when observed data is below the mean and positive when above). Using Cohen's guideline on effect size, the effect size 0.3 is of medium size [132, 133]. The statistics of 0.3 effect size shows there is significant difference of medium magnitude between the proposed algorithm and the existing algorithms.

The ICSO algorithm is shown [114] to have better performance, minimum STD, minimum
execution time and good success rates than the comparison algorithms.

\subsection*{5.4 A Dynamic Step-Size Adaptation Roach Infestation Optimization}

Simulation studies were conducted to evaluate the proposed DSARIO algorithm presented in section 3.4. Its performance is evaluated on a set of global optimization test functions shown in Table 18 of Appendix A for dimensions 2, 10 and 30. Its performance was compared with the existing RIO and HRIO statistically in Table 5.28. Figures 5.2 and 5.3 illustrate graphically the comparison performance of DSARIO, RIO and HRIO. The comparison results show that DSARIO performs better than RIO and HRIO.

The test statistic of ANOVA was carried out to determine the significant difference in the performance of DSARIO and RIO with HRIO. The statistic p-value computed from the test is 0.003 as shown in Table 5.29. Since the p-value of the test is less than the literature threshold p-value 0.05 , it means that there is significant difference in the performance of DSARIO and comparison algorithms. The effect size of the significant difference was calculated.
\(\eta^{2}=\) sum of square (between groups)/Total sum of square. From Table 5.29, \(\eta^{2}=194.643 / 438.156=\) 0.44. The effect size 0.44 is very large, according to Cohen's guideline on effect size [132, 133]. The magnitude of the difference between DSARIO and comparison algorithms is very large.

We tested DSARIO on scalable benchmarks up to dimensions 30 as shown in Table 5.27. The algorithm consistently solves the benchmarks to dimension 30 and found optimal minimum values. The graphical illustration of DSARIO performance for dimensions 2, 10 and 30 is shown in Figure 5.3 .

The dynamic step-size adaptation method improved the performance of DSARIO, the improved performance was proved experimentally and statistically over the existing RIO and HRIO [134].

\subsection*{5.5 Empirical Result of Modified Roach Infestation Optimization}

We presented the MRIO model in section 3.6.1 and simulation studies were conducted to evaluate and compare the success of the MRIO compared with HRIO and RIO on a set of global optimization problems as shown in Table 18 of Appendix A. Tables 5.30, 5.31 and 5.32 show the result of the experiments. The comparison performance results of MRIO, RIO and HRIO is shown in Table 5.33 and 5.34 Table 5.33 depicts success performance comparison results of MRIO, HRIO and RIO; MRIO are shown to have better success performance. Table 5.34 shows the comparison of average performance of the three algorithm; MRIO is proved to have better average performance [135]. Minimum optimal values are bold in Table 5.34 .

The MRIO algorithm show improved performance over RIO and HRIO.

\subsection*{5.6 ACSO for Global Optimization Problems Using PPEM}

Empirical studies were carried out using 70 global optimization benchmark problems presented in Table 1920 and 21 of Appendix A to test the successes of the ACSO model shown in section 3.7 and compared with RIO, DSARIO and PSO. The obtained results were statistically analysed and compared.

Several versions of PSO exist in the literature, PSO variant [45] was chosen in this work for high performance. Table 5.35 shows the results of simulation studies carried on ACSO, RIO DSARIO and PSO where the optimum values, mean iterations, mean function evaluations, success rate, normalised success performance and computation time were computed and recorded.

Tables 22, 23, 24 and 25 of Appendix B depict the comparison results of ACSO, RIO, DSARIO and PSO algorithms best, average, standard deviation of Mean, success rate respectively. From the comparison results, generally, ACSO performs better when compared with other algorithms.

Success performance of ACSO, RIO, DSARIO and PSO algorithms were tested. The normalised SP (nSP) was computed by dividing algorithm \(S P\) by the \(S P\) of the best performing algorithm \(\left(S P_{\text {best }}\right)\) for a particular benchmark function. The results of \(n S P\) are shown in the Table 5.35 and Table 26 of Appendix B. The "-" in Table 5.35 and Table 26 of Appendix B indicates that a particular algorithm can not solve a problem successfully.

Comparison of ACSO, RIO, DSARIO and PSO algorithms for the statistic parameters: success rate, mean iteration, mean function evaluation and computation time respectively are given in Tables 5.36, 5.37, 5.38 and 5.39 . This is to determine the number of functions that have equal values of success rate, mean iteration, mean function evaluation and computation time. In Tables 5.36, 5.37, 5.38 and 5.39. SAME denotes the number of functions that have equal values and DIFF denotes number of functions that have different values.

The ANOVA test statistic was conducted on the average performance of ACSO, RIO, DSARIO and PSO algorithms to determine if there was a significant difference. The P-Value from the ANOVA test is 0.3933 , the null hypothesis suggests that there is no significant difference in the average performance of the algorithms. Figure 5.4 illustrates graphically the result of the ANOVA test; Numbers 1-4 on the x-axis denote ACSO, RIO, DSARIO and PSO respectively.

Ave denotes average(mean optima); STD denotes standard deviation of mean optima; SRT denotes success rate; Best denotes best optima; Miter denotes mean iteration. MFE denotes mean function evaluation; Time denotes computation time in seconds; nSP denotes normalized success performance; "-" for nSP indicates that the algorithm can not solve the problem successfully.

\subsection*{5.7 Multi-Valued Discrete Space Cockroach Swarm Optimization}

DCSO model of section 3.8.1 was simulated and its performance evaluated in this section. The performance of the DCSO algorithm with binary, ternary and quaternary base systems was tested on a set of global optimization benchmarks shown in Table 15 of Appendix A and compared with the results of the existing discrete particle swarm optimization (DPSO) [55]. The benchmarks are adopted from [55, 136, 137] and with their characteristics include uni-modal, multi-modal, shifted, rotated, separable, non-separable, scalable, and noise in fitness. Experimental settings of [55] is considered in this study for good comparison; 10 dimensions are considered for the benchmarks, swarm size is \(20, x_{\max }=4\). The algorithm run 25 times for each benchmark with 5000 iterations each. The numerical results of DCSO for binary, ternary and quaternary number bases were recorded in this work after implementing the algorithm. The results are depicted in Table 5.42. The numerical results of DPSO (binary DPSO, ternary DPSO and quaternary DPSO) is as adopted in [55].

The comparison results of DCSO with DPSO [55] is depicted in Tables 5.43 and 5.44. Table 5.43 shows the comparison average performance while Table 5.44 shows comparison standard deviation of the average optimal values of DCSO and DPSO for binary, ternary and quaternary search spaces respectively. The DCSO algorithm is shown statistically to have improved performance over DPSO algorithm. The DCSO algorithm has consistent performance in each iteration. This is proved by low standard deviation of the optimal mean in Table 5.42 .

Mann-Whitney U-test statistic test was carried out in this work for algorithm performance comparison. This is to determine if DCSO algorithm performance is significantly different from that of the DPSO algorithm. Results of the Mann-Whitney U-test is shown in Tables 5.40 and 5.41 . P-values (Asymp. Sig.) for the Mann-Whitney U-test shown in Table 5.41 is 0.005 , it is less than the threshold value 0.05 . Therefore there is significant difference in the performance of DCSO and DPSO on the selected benchmark problems.

Table 5.40: Mann-Whitney U-test statistics on the performance of DCSO and DPSO.
Ranks
\begin{tabular}{lllll}
\hline \hline & Algorithm & N & Mean Rank & Sum of Ranks \\
\hline Fitness & 1.00 & 15 & 11.00 & 165.00 \\
& 2.00 & 15 & 20.00 & 300.00 \\
& Total & 30 & & \\
\hline
\end{tabular}

The effect size \(r\) of the significant difference was computed from Mann-Whitney U-test of Tables 5.40 and 5.41 \(r=Z / \sqrt{N} ; Z=-2.808\) and \(N=30\) (total number of samples). Effect size \(r\)

Table 5.41: Mann-Whitney U-test statistics.

Test Statistics \({ }^{b}\)
\begin{tabular}{ll}
\hline \hline & Fitness \\
\hline Mann-Whitney U & 45.000 \\
Wilcoxon W & 165.000 \\
Z & -2.808 \\
Asymp.Sig(2 tailed) & .005 \\

\end{tabular}
is calculated to be -0.4870 ( \(Z\) is negative when observed data is below the mean and positive when above). The effect size 0.4870 is of large effect size (close to large effect size of 0.5 ), using the Cohen guideline on effect size [132, 133], \(r\) [Small : 0.1,Medium : 0.3, Large : 0.5]. This means that there is a difference of a large magnitude in the performance of DCSO and DPSO.

\subsection*{5.8 DCSO-TSP}

DCSO application to TSP described in section 3.8.2 was simulated and tested on 53 instances of TSP taken from TSP library [123] to validate its feasibility and effectiveness. Two stages of experiments were conducted. Stage one experiments compared the results of DSCO-TSP with the results of existing CSO and PSO for TSP for the OLIVER 30 problem reported by Cheng et al., [95] using the same experimental settings of 200 cockroaches, 1000 maximum iterations and the experiment runs 8 times. The comparison results depicted in Table 5.45 show that DCSO-TSP also finds the optimum path of 423.74 like the comparison algorithm. Figures 5.5 and 5.6 depict the graphical illustration of results of the proposed algorithm on Oliver 30 instance.

The stage two experiments were conducted to evaluate the algorithm on many instances of TSP. DCSO-TSP was used to solve 52 TSP instances and compared with the results of hybrid genetic algorithm presented by Ahmed [138] for symmetric TSP instances. We used the experimental settings of [138] for the experiments; 20 population size and 20 trials. Maximum iteration 10E4 was used for our experiments.

The results of the experiments of DCSO-TSP were recorded: Best solution, percentage errors \((\operatorname{Error}(\%))\) of the best solution, average solution and average complete computational time (CTime) are depicted in Table 5.46. The percentage errors were computed using equation (5.1). The results of HGA is as recorded by Ahmed [138]. Tables 5.47 and 5.48 show the comparison results of DSCO-TSP and HGA. The comparison results show that DCSO-TSP is able to compete with the well-known GA for evaluating 52 TSP instances. Comparison results show that DCSOTSP is able to obtain better tour for some instances than HGA such as burma 14, ulysses 16, dantzig 42, ulysses 22 , and gr 99 .
\[
\begin{equation*}
\text { Error }=\frac{\left|f\left(x^{*}\right)-f_{\text {min }}\right|}{f\left(x^{*}\right)} \times 100 \% \tag{5.1}
\end{equation*}
\]

Table 5.46 shows the results of DCSO-TSP for 52 instances from a small number of cities to a large number of cities. Figures 1, 23,4, 5, 6, 7, 8, 9,10, 11 and 12 of Appendix C depicts the graphical illustration of results of the DCSO-TSP for 14, 42, 225, 280, 262 and 299 cities respectively. The Figures show the total distance (minimum distance), the city locations and the solution found so far for each instance.

ANOVA test statistic was conducted on the best and average solutions of HGA and DCSO-TSP to verify significant difference. The P-Value from the ANOVA test is 0.237 and 0.348 for best and average solutions respectively. The null hypothesis suggests that there is no significant difference in the best and average performances of HGA and DCSO in solving TSP problems. Tables 5.49 and 5.50 show the results of the ANOVA test for the best and average solutions.
Table 5.45: Performance of DCSO-TSP, CSO and PSO on OLIVER 30 TSP Instance

\section*{Chapter 6}

\section*{Discussion and Conclusion}

\subsection*{6.1 Discussion}

The effects of the new components, operators and methods introduced into RBA to evolve the improved RBA have been shown through empirical and statistical analysis results. The searching abilities, convergence speed, exploitation and exploration have been enhanced as shown in the improved performance of RBA variants over the existing RBA and PSO algorithms shown in Chapter 5.

The effect of stochastic constriction on characteristics of the CSO algorithm is shown in this work in section 5.2. Simulation results revealed that the proposed SCCSO algorithm has good convergence capability. A constriction factor enabled the algorithm to maintain swarm stability and enhances local and global searches which resulted in improved convergence and speed of the algorithm. The SCCSO algorithm runs fast, solving benchmark problems up to 3000 dimensions, without modifying the algorithm, and it can evaluate a higher number of variables above 3000 dimensions. Comparisons of results of SCCSO with the existing CSO and MCSO show its superiority. A comparison of SCCSO with LSRS which has been proved in the literature, for high dimensions up to 2000, shows SCCSO has the ability to compete with existing global optimization technique.

A further improvement was made on the CSO algorithm by extending it with a hunger component whereby enhancing the algorithm's diversity and searching capabilities. ICSO is proposed, and the efficiency of the proposed algorithm has been shown through empirical studies where its performance was compared with that of existing RBA: CSO, MSCO, RIO and HRIO. Results show that ICSO is significantly better than the existing algorithms. The statistics of 0.3 effect size shows there is a significant difference of medium magnitude between the proposed algorithm and the existing algorithms. The Jonckheere-Terpstra test statistic was used for the statistical analysis to
compare the results of ICSO with existing algorithms. Test statistic results revealed that there is a significant difference of medium magnitude in the performance of ICSO with CSO, MCSO, RIO and HRIO algorithms.

Likewise, the effect of a simple Euler step-size adaptation is examined on a RIO algorithm. Simulation studies show improved performance of the proposed DSARIO algorithm over RIO and HRIO algorithms. The numerical results show that DSARIO solves multi-dimensional benchmark problems, where it was tested up to 30 dimensions, and it can still solve a higher number of variables without modification. The evaluation of the results of the algorithms were carried out by test statistics of analysis of variance (ANOVA). The results of ANOVA shows there is a significant difference of very large effect in the performance of DSARIO and that of RIO and HRIO.

Also, the MRIO algorithm that is tied to the social behaviour of cockroaches is presented in this work to improve on the original RIO algorithm. Modification of the existing RIO models was done and two new components namely vigilance and cannibalism were added. MRIO was evaluated on known function benchmarks empirically, and the proposed algorithm found global optimal for the selected benchmarks. The superiority of MRIO to the exiting RIO and HRIO was revealed through performance comparisons.

Moreover, the introduction of PPEM with crossover and mutation techniques to the CSO algorithm helped the algorithm to create adaptive searches in each iteration enhancing population diversity and local and global searches as revealed by improved results through simulation studies. 70 global optimization benchmark problems were used to evaluate the success of ACSO, RIO, DSARIO and PSO and their results were statistically compared. The searching techniques of ACSO are similar to DSARIO in that, they both create adaptive searches in each iteration maintaining a balance of exploitation and exploration. The Euler step-size \(h\) created adaptive searches and enhanced swarm stability in DSARIO. PSO and RIO have similar searching methods but RIO has the greater capability of escaping local convergence than has PSO. The find food component of RIO enhances diversity. The known stability problem of PSO limits its success rate despite its ability to solve many benchmark functions. From the comparison results, ACSO performs better that the comparison algorithms.

Finally, the proposed multi-valued discrete cockroach swarm optimization (DCSO) algorithm was tested using standard test function benchmarks and compared with discrete particle swarm optimization (DPSO). Empirical and statistical analysis results show that DCSO outperforms DPSO. The proposed algorithm was also applied to TSP using 53 instances of TSP problems from TSPLIB. The results of DCSO on TSP were compared with the results of existing CSO, PSO and HGA from the literature; the comparison results show similar performance.

\subsection*{6.2 Summary of Findings}

This thesis set out to improve the performance of the existing RBA. The research work achieved its stated objectives which are: proposing improved RBAs from the existing RBA; making RBA a global optimization technique with improved convergence on global optima by extending its models; constructing and testing adaptive RBAs based on methods and models that have been proven to be successful when applied to other evolutionary techniques; constructing and testing discrete value space RBA for solving global optimization problems with discrete values, based on the methods that have been successfully applied to other SI techniques and evaluation of the proposed RBA variants with standard global optimization test problems and comparing the obtained results with those in the literature.

The speed and the performance of the CSO algorithm was improved by the incorporation of a stochastic constriction factor. In this thesis a stochastic constriction cockroach swarm optimization that is able to solve problems with thousands of variables was developed.

The thesis set out to improve the searching abilities of the CSO algorithm by the inclusion of an additional component called hunger. The hunger component enhanced diversity, exploitation and exploration of the algorithm.

Furthermore, predator-prey evolution with cross over and mutation approach were employed to create an adaptive search. The CSO algorithm is able to recursively create a pattern matrix in each iteration which improves exploitation, exploration and good convergence. The technique ultimately helps the algorithm to avoid getting trapped at local optima. Diversity is introduced into a population by mutation, whenever the population tends to converge at a local optimal point. Also a point is created in the neighbourhood of the current point by a mutation process, which allows a local search around the point. The technique also helps the algorithm to avoid the possibility of population collapse through the evolution process.

Real world problems are majorly discrete-valued in nature. This thesis extends the existing CSO algorithm that was primarily designed for continuous problems and constructs a multi-valued discrete algorithm. This is achieved with the use of sigmoid function and an operator for the logistic transformation of values and the generation of a solution that is rounded to the nearest discrete variable.

Similarly, the RIO algorithm was improved upon by the engagement of a simple Euler step-size adaptation method. This technique helps RIO to avoid falling into local optimum by maintaining balance between exploitation and exploration. The technique also enhances swarm stability.

Furthermore, the performance and the searching ability of RIO were greatly enhanced by redesigning the existing components and the incorporation of two additional components namely vigilance and cannibalism in the modifications. The vigilance component creates population di-
versity, as cockroaches are able to explore the search region for a solution. The cannibalism component enhances both local and global searches.

Finally, the performance of the improved algorithms have been compared with existing algorithms, both empirically and statistically. The comparison results confirmed the superiority of the improved algorithms over the existing algorithms.

The new components and operators, introduced into cockroach algorithms to evolve into the improved algorithms have been discussed and shown to perform better than the existing algorithms.

\subsection*{6.3 Suggestions for Future Research}

Every answered questions makes room for many new ones to come to light. A few thoughts for extensions and future work are highlighted below:
1. Constrained global optimization problems: In this thesis, the improved algorithms were used mainly for solving unconstrained continuous optimization problems. Application of the improved RBA to various constrained problems is recommended for further work.
2. Combinatorial optimization problems: The developed discrete-valued cockroach swarm optimization was tested on TSP. Its application to more combinatorial optimization problems is recommended.
3. Multi-objective RBA Optimization: Most real world problems are situations where decision making involves a trade-offs between two or more conflicting objectives. Scenarios such as product and design, automobile design, finance, aircraft design, and the oil and gas industry. Cockroach algorithms have searching strategies that can be used for multi-objective optimization. Extension of the improved algorithms for multi-objective problems can be followed up.
4. Hybridization of improved RBA with various techniques: Development of hybrid cockroach algorithms is another possible extension of this work. Cockroach algorithm can be hybridized with techniques such as Simulated Annealing, Tabu search etc. for better performance.

\section*{Appendices}

\section*{Appendix A: Standard Global Optimization Benchmark Test Functions}

A large test suite that include a wide variety of problems such as unimodal, multimodal, regular, irregular, separable, non-separable, and multidimensional are presented in this Appendix I. Some of these problems can be found in optimization books, research articles or different optimization websites. A collection of these problems can be found [139, 140, 141]. These are minimization problems for unconstrained optimization. These optimization problems were used to validate the performance of the improved cockroach optimization algorithms. The dimension, problem domain size and the optimal solution are denoted by \(D, L b \leq x i \leq U b\) and \(f\left(x^{*}\right)=f\left(x_{1}, \ldots, x_{n}\right)\) respectively. \(L b\) and \(U b\) denote lower and upper bounds of the variables respectively. It should be noted that in several cases the optimal point vector and corresponding global point are known only as a numerical approximation.

\section*{1. Aluffi-Pentini's Problem}
\[
\begin{array}{cc}
\min _{x} f(x)= & 0.25 x_{1}^{4}-0.5 x_{1}^{2}+0.1 x_{1}+0.5 x_{2}^{2} \\
\text { subject to } & -10 \leq x_{1}, x_{2} \leq 10 . \tag{2}
\end{array}
\]

The function has two local minimal, one of them is global with \(f\left(x^{*}\right) \approx-0.3523\) located at (-1.0465, 0).

\section*{2. Becker and Lago Problem}
\[
\begin{gather*}
\min _{x} f(x)=  \tag{3}\\
\text { subject to }  \tag{4}\\
\text { sul } \\
\quad-10 \leq x_{1}, x_{2} \leq 10 .
\end{gather*}
\]

The function has four minima located at \(( \pm 5, \pm 5)\), all with \(f\left(x^{*}\right)=0\).

\section*{3. Bohachevsky 1 Problem}
\[
\begin{array}{cc}
\min _{x} f(x)=x_{1}^{2}+2 x_{2}^{2}-0.3 \cos \left(3 \pi x_{1}\right)-0.4 \cos \left(4 \pi x_{2}\right)+0.7 \\
\text { subject to } & -50 \leq x_{1}, x_{2} \leq 50 \tag{6}
\end{array}
\]

The number of local minimal is unknown but the global minimizer is located at \(x^{*}=(0,0)\) with \(f\left(x^{*}\right)=0\).

\section*{4. Bohachevsky 2 Problem}
\[
\begin{array}{cc}
\min _{x} f(x)=x_{1}^{2}+2 x_{2}^{2}-0.3 \cos \left(3 \pi x_{1}\right) \cos \left(4 \pi x_{2}\right)+0.3 \\
\text { subject to } & -50 \leq x_{1}, x_{2} \leq 50 . \tag{8}
\end{array}
\]

The number of local minimal is unknown but the global minimizer is located at \(x^{*}=(0,0)\) with \(f\left(x^{*}\right)=0\).

\section*{5. Branin Problem}
\[
\begin{array}{cc}
\min _{x} f(x)=a\left(x_{2}-b x_{1}^{2}+c x_{1}-d\right)^{2}+g(1-h) \cos \left(x_{1}\right)+g \\
\text { subject to } & -5 \leq x_{1} \leq 10,0 \leq x_{2} \leq 15 \tag{10}
\end{array}
\]
where \(a=1, b=5.1 /\left(4 \pi^{2}\right), c=5 / \pi, d=6, g=10, h=1 /(8 \pi)\). There are three minima, all global, in this region. The minimizers are \(x^{*} \approx(-\pi, 12.275),(\pi, 2.275),(3 \pi, 2.475)\) with \(f\left(x^{*}\right)=5 /(4 \pi)\).

\section*{6. Camel Back-3 Three Hump Problem}
\[
\begin{array}{cc}
\min _{x} f(x)= & 2 x_{1}^{2}-1.05 x_{1}^{4}+\frac{1}{6} x_{1}^{6}+x_{1} x_{2}+x_{2}^{2} \\
\text { subject to } & -5 \leq x_{1}, x_{2} \leq 5 \tag{12}
\end{array}
\]

The function has three local minima, one of them is global located at \(x^{*}=(0,0)\) with \(f\left(x^{*}\right)=\) 0 .

\section*{7. Camel Back-6 Six Hump Problem}
\[
\begin{array}{cc}
\min _{x} f(x)=4 x_{1}^{2}-2.1 x_{1}^{4}+\frac{1}{3} x_{1}^{6}+x_{1} x_{2}-4 x_{2}^{2}+4 x_{2}^{4} \\
\text { subject to } & -5 \leq x_{1}, x_{2} \leq 5 . \tag{14}
\end{array}
\]

This function is symmetric about the origin and has three conjugate pairs of local minima with values \(f \approx-1.0316,-0.2154,2.1042\). The function has two global minima at \(x^{*} \approx\) \((0.089842,-0.712656)\) and \((-0.089842,0.712656)\) with \(f\left(x^{*}\right) \approx-1.0316\).

\section*{8. Cosine Mixture Problem}
\[
\begin{align*}
\max _{x} f(x)= & 0.1 \sum_{i=1}^{n} \cos \left(5 \pi x_{i}\right)-\sum_{i=1}^{n} x_{i}^{2}  \tag{15}\\
\text { subject to } & -1 \leq x_{i} \leq 1, i \in\{1,2, \ldots, n\} . \tag{16}
\end{align*}
\]

The global maxima are located at the origin with the function values 0.20 and 0.40 for \(n=2\) and \(n=4\), respectively.

\section*{9. Dekkers and Aarts Problem}
\[
\begin{array}{cc}
\min _{x} f(x)=10^{5} x_{1}^{2}+x_{2}^{2}-\left(x_{1}^{2}+x_{2}^{2}\right)^{2}+10^{-5}\left(x_{1}^{2}+x_{2}^{2}\right)^{4} \\
\text { subject to } & -20 \leq x_{1}, x_{2} \leq 20 . \tag{18}
\end{array}
\]

The origin is a local minimizer, but there are two global minimizer located at \(x^{*}=(0,15)\) and \((0,-15)\) with \(f\left(x^{*}\right)=-24776.518\).

\section*{10. Easom Problem (EP)}
\[
\begin{array}{cc}
\min _{x} f(x)=-\cos \left(x_{1}\right) \cos \left(x_{2}\right) \exp \left(-\left(x_{1}-\pi\right)^{2}-\left(x_{2}-\pi\right)^{2}\right) \\
\text { subject to } & -10 \leq x_{1}, x_{2} \leq 10 . \tag{20}
\end{array}
\]

The minimum value is located at \((\pi, \pi)\) with \(f\left(x^{*}\right)=-1\). The function value rapidly approaches zero, when away from \((\pi, \pi)\).

\section*{11. Goldstein and Price}
\[
\begin{array}{cc}
\min _{x} f(x)= & {\left[1+\left(x_{1}+x_{2}+1\right)^{2}\left(19-14 x_{1}+3 x_{1}^{2}-14 x_{2}+6 x_{1} x_{2}+3 x_{2}^{2}\right)\right]} \\
& \times\left[30+\left(2 x_{1}-3 x_{2}\right)^{2}\left(18-32 x_{1}+12 x_{1}^{2}+48 x_{2}-36 x_{1} x_{2}+27 x_{2}^{2}\right)\right] \\
\text { subject to } & -2 \leq x_{1}, x_{2} \leq 2 \tag{22}
\end{array}
\]

There are four local minima and the global minima is located at \(x^{*}=(0,-1)\), with \(f\left(x^{*}\right)=3\).

\section*{12. Hosaki Problem}
\[
\begin{array}{cc}
\min _{x} f\left(x_{1}, x_{2}\right)= & \left(1-8 x_{1}+7 x_{1}^{2}-\frac{7}{3} x_{1}^{3}+\frac{1}{4} x_{1}^{4}\right) x_{2}^{2} \exp \left(-x_{2}\right) \\
\text { subject to } & 0 \leq x_{1} \leq 5,0 \leq x_{2} \leq 6 \tag{24}
\end{array}
\]

There are two minima of which the global minimum is \(f\left(x^{*}\right) \approx-2.3458\) with \(x^{*}=(4,2)\).

\section*{13. McCormick Problem}
\[
\begin{array}{cc}
\min _{x} f(x)= & \sin \left(x_{1}+x_{2}\right)+\left(x_{1}-x_{2}\right)^{2}-(3 / 2) x_{1}+(5 / 2) x_{2}+1 \\
\text { subject to } & -1.5 \leq x_{1} \leq 4,-3 \leq x_{2} \leq 3 \tag{26}
\end{array}
\]

This problem has a local minimum at \((2.59,1.59)\) and a global minimum at \((-0.547,-1.547)\) with \(f\left(x^{*}\right) \approx-1.9133\).

\section*{14. Modified Rosenbrock Problem}
\[
\begin{array}{cc}
\min _{x} f(x)=100\left(x_{2}-x_{1}^{2}\right)^{2}+\left[6.4\left(x_{2}-0.5\right)^{2}-x_{1}-0.6\right]^{2} \\
\text { subject to } & -5 \leq x_{1}, x_{2} \leq 5 . \tag{28}
\end{array}
\]

This function has two global minima each with \(f\left(x^{*}\right)=0\) (corresponding to the intersection of two parabolas) and a local minimum (where the parabolas approach without intersection). The global minima are located at \(x^{*} \approx(0.3412,0.1164),(1,1)\).

\section*{15. Multi-Gaussian Problem}
\[
\begin{array}{cc}
\max _{x} f(x)=\sum_{i=1}^{5} a_{i} \exp \left(-\left(\left(x_{1}-b_{i}\right)^{2}+\left(x_{2}-c_{i}\right)^{2}\right) / d_{i}^{2}\right) \\
\text { subject to } & -2 \leq x_{1}, x_{2} \leq 2 \tag{30}
\end{array}
\]

The function has one global maximum at \(x^{*} \approx(-0.01356,-0.01356)\) with \(f\left(x^{*}\right) \approx 1.29695\). There are also 4 other local maxima and a saddle point. Values for the parameters \(a_{i}, b_{i}, c_{i}\), and \(d_{i}\) are given in Table 1 .

Table 1: Appendix: Data for Multi-Gaussian problem
\begin{tabular}{rrrrr}
\hline\(i\) & \(a_{i}\) & \(b_{i}\) & \(c_{i}\) & \(d_{i}\) \\
\hline 1 & 0.5 & 0.0 & 0.0 & 0.1 \\
2 & 1.2 & 1.0 & 0.0 & 0.5 \\
3 & 1.0 & 0.0 & -0.5 & 0.5 \\
4 & 1.0 & -0.5 & 0.0 & 0.5 \\
5 & 1.2 & 0.0 & 1.0 & 0.5 \\
\hline
\end{tabular}

\section*{16. Periodic Problem}
\[
\begin{array}{cc}
\min _{x} f(x)= & 1+\sin ^{2} x_{1}+\sin ^{2} x_{2}-0.1 \exp \left(-x_{1}^{2}-x_{2}^{2}\right) \\
\text { subject to } & -10 \leq x_{1}, x_{2} \leq 10 \tag{32}
\end{array}
\]

There are 49 local minima all with minimum values 1 and global minimum located at \(x^{*}=\) \((0,0)\) with \(f\left(x^{*}\right)=0.9\).

\section*{17. Schaffer 1 Problem}
\[
\begin{array}{cc}
\min _{x} f(x)= & 0.5+\frac{\left(\sin \sqrt{x_{1}^{2}+x_{2}^{2}}\right)^{2}-0.5}{\left(1+0.001\left(x_{1}^{2}+x_{2}^{2}\right)\right)^{2}} \\
\text { subject to } & -100 \leq x_{1}, x_{2} \leq 100 \tag{34}
\end{array}
\]

The number of local minima is not known, but the global minimum is located at \(x^{*}=(0,0)\) with \(f\left(x^{*}\right)=0\).

\section*{18. Schaffer 2 Problem}
\[
\begin{array}{cc}
\min _{x} f(x)= & \left(x_{1}^{2}+x_{2}^{2}\right)^{0.25}\left(\sin ^{2}\left(50\left(x_{1}^{2}+x_{2}^{2}\right)^{0.1}\right)+1\right) \\
\text { subject to } & -100 \leq x_{1}, x_{2} \leq 100 \tag{36}
\end{array}
\]

The number of local minima is not known, but the global minimum is located at \(x^{*}=(0,0)\) with \(f\left(x^{*}\right)=0\).

\section*{19. Schubert Problem}
\[
\begin{array}{cc}
\min _{x} f(x)= & \prod_{i=1}^{n}\left(\sum_{j=1}^{5} j \cos \left((j+1) x_{i}+j\right)\right) \\
\text { subject to } & -10 \leq x_{i} \leq 10, i \in\{1,2, \ldots, n\} \tag{38}
\end{array}
\]

Our tests were performed with \(n=2\). The number of local minima for this problem (given \(n\) ) is not known but for \(n=2\), the function has 760 local minima, 18 of which are global with \(f\left(x^{*}\right) \approx-186.7309\). All two dimensional global minimizers are listed in Table 2 ;

Table 2: Global optimizers for Schubert problem
\begin{tabular}{ccccc}
\hline \multicolumn{5}{c}{\(x^{*}\)} \\
\hline\((-7.0835,4.8580)\), & \((-7.0835,-7.7083)\), & \((-1.4251,-7.0835)\), & \((5.4828,4.8580)\), & \((-1.4251,-0.8003)\), \\
\((4.8580,5.4828)\), & \((-7.7083,-7.0835)\), & \((-7.0835,-1.4251)\), & \((-7.7083,-0.8003)\), & \((-7.7083,5.4828)\), \\
\((-0.8003,-7.7083)\), & \((-0.8003,-1.4251)\), & \((-0.8003,4.8580)\), & \((-1.4251,5.4828)\), & \((5.4828,-7.7083)\), \\
\((4.8580,-7.0835)\), & \((5.4828,-1.4251)\), & \((4.8580,-0.8003)\) & & \\
\hline
\end{tabular}

\section*{20. Gulf Research Problem}
\[
\begin{array}{cc}
\min _{x} f(x)= & \sum_{i=1}^{99}\left[\exp \left(-\frac{\left(u_{i}-x_{2}\right)^{x_{3}}}{x_{1}}\right)-0.01 \times i\right]^{2} \\
\text { subject to } & 0.1 \leq x_{1} \leq 100,0 \leq x_{2} \leq 25.6, \text { and } 0 \leq x_{3} \leq 5, \tag{40}
\end{array}
\]
where \(u_{i}=25+[-50 \ln (0.01 \times i)]^{1 / 1.5}\) This problem has a global minimizer at \((50,25,1.5)\) with \(f\left(x^{*}\right)=0\).

\section*{21. Hartman 3 Problem}
\[
\begin{array}{cc}
\min _{x} f(x)= & -\sum_{i=1}^{4} c_{i} \exp \left[-\sum_{j=1}^{3} a_{i j}\left(x_{j}-p_{i j}\right)^{2}\right] \\
\text { subject to } & 0 \leq x_{j} \leq 1, j \in\{1,2,3\} \tag{42}
\end{array}
\]
with constants \(a_{i j}, p_{i j}\) and \(c_{i}\) given in Table 3. There are four local minima, \(x_{l o c a l} \approx\left(p_{i 1}, p_{i 2}, p_{i 3}\right)\) with \(f\left(x_{\text {local }}\right) \approx-c_{i}\). The global minimum is located at \(x^{*} \approx(0.114614,0.555649,0.852547)\) with \(f\left(x^{*}\right) \approx-3.862782\).

Table 3: Data for Hartman 3 problem
\begin{tabular}{rrrrrrrr}
\hline\(i\) & \(c_{i}\) & \multicolumn{3}{c}{\(a_{i j}\)} & \multicolumn{3}{c}{\(p_{i j}\)} \\
\cline { 2 - 8 } & & \(j=1\) & 2 & 3 & \(j=1\) & 2 & 3 \\
\hline 1 & 1.0 & 3.0 & 10 & 30 & 0.36890 & 0.1170 & 0.2673 \\
2 & 1.2 & 0.1 & 10 & 35 & 0.46990 & 0.4387 & 0.7470 \\
3 & 3.0 & 3.0 & 10 & 30 & 0.10910 & 0.8732 & 0.5547 \\
4 & 3.2 & 0.1 & 10 & 35 & 0.03815 & 0.5743 & 0.8828 \\
\hline
\end{tabular}

\section*{22. Helical Valley Problem}
\[
\begin{array}{cc}
\min _{x} f(x)=100\left[\left(x_{2}-10 \theta\right)^{2}+\left(\sqrt{\left(x_{1}^{2}+x_{2}^{2}\right)}-1\right)^{2}\right]+x_{3}^{2} \\
\text { subject to } & -10 \leq x_{1}, x_{2}, x_{3} \leq 10 \tag{44}
\end{array}
\]
where
\[
\theta= \begin{cases}\frac{1}{2 \pi} \tan ^{-1} \frac{x_{2}}{x_{1}}, & \text { if } x_{1} \geq 0  \tag{45}\\ \frac{1}{2 \pi} \tan ^{-1} \frac{x_{2}}{x_{1}}+\frac{1}{2}, & \text { if } x_{1}<0\end{cases}
\]

This is a steep-sided valley which follows a helical path. The minimum is located at \(x^{*}=\) \((1,0,0)\) with \(f\left(x^{*}\right)=0\).

\section*{23. Levy and Montalvo 1 Problem (LM1)}
\[
\begin{array}{cc}
\min _{x} f(x)=\frac{\pi}{n}\left(10 \sin ^{2}\left(\pi y_{1}\right)+\sum_{i=1}^{n-1}\left(y_{i}-1\right)^{2}\left[1+10 \sin ^{2}\left(\pi y_{i+1}\right)\right]\right) \\
& +\frac{\pi}{n}\left(y_{n}-1\right)^{2} \\
\text { subject to } & -10 \leq x_{i} \leq 10, i \in\{1,2, \ldots, n\} \tag{47}
\end{array}
\]
where \(y_{i}=1+\frac{1}{4}\left(x_{i}+1\right)\). There are approximately \(5^{n}\) local minima and the global minimum is known to be \(f\left(x^{*}\right)=0\) with \(x^{*}=(-1,-1, \ldots,-1)\). Our tests were performed with \(n=3\).

\section*{24. Meyer and Roth Problem (MR)}
\[
\begin{array}{cc}
\min _{x} f(x)= & \sum_{i=1}^{5}\left(\frac{x_{1} x_{3} t_{i}}{\left(1+x_{1} t_{i}+x_{2} v_{i}\right)}-y_{i}\right)^{2} \\
\text { subject to } & -20 \leq x_{i} \leq 20, i \in\{1,2,3\} . \tag{49}
\end{array}
\]

This is a least squares problem with minimum value \(f\left(x^{*}\right) \approx 0.4 \times 10^{-4}\) located at \(x^{*} \approx\) \((3.13,15.16,0.78)\). Table 4 lists the parameter values of this problem.

Table 4: Data for Meyer and Roth problem
\begin{tabular}{rrrr}
\hline\(i\) & \(t_{i}\) & \(v_{i}\) & \(y_{i}\) \\
\hline 1 & 1.0 & 1.0 & 0.126 \\
2 & 2.0 & 1.0 & 0.219 \\
3 & 1.0 & 2.0 & 0.076 \\
4 & 2.0 & 2.0 & 0.126 \\
5 & 0.1 & 0.0 & 0.186 \\
\hline
\end{tabular}

\section*{25. Cosine Mixture Problem}

Same as problem number 8, but tests were performed with \(n=4\).

\section*{26. Kowalik Problem (KL)}
\[
\begin{array}{cc}
\min _{x} f(x)= & \sum_{i=1}^{11}\left(a_{i}-\frac{x_{1}\left(1+x_{2} b_{i}\right)}{\left(1+x_{3} b_{i}+x_{4} b_{i}^{2}\right.}\right)^{2} \\
\text { subject to } & 0 \leq x_{i} \leq 0.42, i \in\{1,2,3,4\} \tag{51}
\end{array}
\]

The values for \(a_{i}\) and \(b_{i}\) are given in Table 5:
Table 5: Data for Kowalik problem
\begin{tabular}{rrrrrrrrrrrr}
\hline\(i\) & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 \\
\hline\(a_{i}\) & 0.1957 & 0.1947 & 0.1735 & 0.16 & 0.0844 & 0.0627 & 0.0456 & 0.0342 & 0.0323 & 0.0235 & 0.0246 \\
\(b_{i}\) & 0.25 & 0.50 & 1.0 & 2.0 & 4.0 & 6.0 & 8.0 & 10.0 & 12.0 & 14.0 & 16.0 \\
\hline
\end{tabular}

This is a least squares problem with a global optimal value \(f\left(x^{*}\right) \approx 3.0748 \times 10^{-4}\) located at \(x^{*} \approx(0.192,0.190,0.123,0.135)\).

\section*{27. Miele and Cantrell Problem}
\[
\begin{array}{cc}
\min _{x} f(x)= & \left(\exp \left(x_{1}\right)-x_{2}\right)^{4}+100\left(x_{2}-x_{3}\right)^{6}+\left(\tan \left(x_{3}-x_{4}\right)\right)^{4}+x_{1}{ }^{8} \\
\text { subject to } & -1 \leq x_{i} \leq 1, i \in\{1,2,3,4\} . \tag{53}
\end{array}
\]

The number of local minima is unknown but the global minimizer is located at \(x^{*}=(0,1,1,1)\) with \(f\left(x^{*}\right)=0\).

\section*{28. Neumaier 2 Problem}
\[
\begin{array}{cc}
\min _{x} f(x)= & \sum_{k=1}^{n}\left(b_{k}-\sum_{i=1}^{n} x_{i}^{k}\right)^{2} \\
\text { subject to } & 0 \leq x_{i} \leq n, i \in\{1,2, \ldots, n\} . \tag{55}
\end{array}
\]

We consider a case when \(n=4\) and \(b=(8,18,44,114)\). The global minimum is \(f(1,2,2,3)=\) 0 .

\section*{29. Powell's Quadratic Problem (PWQ)}
\[
\begin{array}{cc}
\min _{x} f(x)=\left(x_{1}+10 x_{1}\right)^{2}+5\left(x_{3}-x_{4}\right)^{2}+\left(x_{2}-2 x_{3}\right)^{4}+10\left(x_{1}-x_{4}\right)^{4} \\
\text { subject to } & -10 \leq x_{i} \leq 10, i \in\{1,2,3,4\} . \tag{57}
\end{array}
\]

This is a unimodal function with \(f\left(x^{*}\right)=0, x^{*}=(0,0,0,0)\). The minimizer is difficult to obtain with accuracy as the Hessian matrix at the optimum is singular.

\section*{30. Shekel 5 Problem}
\[
\begin{gather*}
\min _{x} f(x)=\quad-\sum_{i=1}^{5} \frac{1}{\sum_{j=1}^{4}\left(x_{j}-a_{i j}\right)^{2}+c_{i}}  \tag{58}\\
\text { subject to } \quad 0 \leq x_{j} \leq 10, j \in\{1,2,3,4\} \tag{59}
\end{gather*}
\]
with constants \(a_{i j}\) and \(c_{j}\) given in Table 6 below. There are five local minima and the global minimizer is located at \(x^{*}=(4.00,4.00,4.00,4.00)\) with \(f\left(x^{*}\right) \approx-10.1532\).

\section*{31. Shekel 7 Problem}
\[
\begin{array}{cc}
\min _{x} f(x)= & -\sum_{j=1}^{7} \frac{1}{\sum_{i=1}^{4}\left(x_{j}-a_{i j}\right)^{2}+c_{i}} \\
\text { subject to } & 0 \leq x_{j} \leq 10, j \in\{1,2,3,4\} \tag{61}
\end{array}
\]

Table 6: Data for Shekel problem family
\begin{tabular}{crrrrrr}
\hline & & \multicolumn{5}{c}{\(a_{i j}\)} \\
& \(i\) & \(c_{i}\) \\
\cline { 3 - 6 } & & \(j=1\) & 2 & 3 & 4 & \\
\hline S5 & 1 & 4 & 4 & 4 & 4 & 0.1 \\
& 2 & 1 & 1 & 1 & 1 & 0.2 \\
& 3 & 8 & 8 & 8 & 8 & 0.2 \\
& 4 & 6 & 6 & 6 & 6 & 0.4 \\
& 5 & 3 & 7 & 3 & 7 & 0.4 \\
\hline S7 & 6 & 2 & 9 & 2 & 9 & 0.6 \\
& 7 & 5 & 5 & 3 & 3 & 0.3 \\
\hline S10 & 8 & 8 & 1 & 8 & 1 & 0.7 \\
& 9 & 6 & 2 & 6 & 2 & 0.5 \\
& 10 & 7 & 3.6 & 7 & 3.6 & 0.5 \\
\hline
\end{tabular}
with constants \(a_{i j}\) and \(c_{j}\) given in Table 6. There are seven local minima and the global minimizer is located at \(x^{*}=(4.00,4.00,4.00,4.00)\) with \(f\left(x^{*}\right) \approx-10.4029\).

\section*{32. Shekel 10 Problem}
\[
\begin{array}{cc}
\min _{x} f(x)= & -\sum_{j=1}^{10} \frac{1}{\sum_{i=1}^{4}\left(x_{j}-a_{i j}\right)^{2}+c_{i}} \\
\text { subject to } & 0 \leq x_{j} \leq 10, j \in\{1,2,3,4\} \tag{63}
\end{array}
\]
with constants \(a_{i j}\) and \(c_{j}\) given in Table 6. There are 10 local minima and the global minimizer is located at \(x^{*}=(4.00,4.00,4.00,4.00)\) with \(f\left(x^{*}\right) \approx-10.5364\).

\section*{33. Wood's Problem}
\[
\begin{array}{cc}
\min _{x} f(x)= & 100\left(x_{2}-x_{1}^{2}\right)^{2}+\left(1-x_{1}\right)^{2}+90\left(x_{4}-x_{3}^{2}\right)^{2}+\left(1-x_{3}\right)^{2} \\
& +10.1\left[\left(x_{2}-1\right)^{2}+\left(x_{4}-1\right)^{2}\right]+19.8\left(x_{2}-1\right)\left(x_{4}-1\right) \\
\text { subject to } & -10 \leq x_{i} \leq 10, i \in\{1,2,3,4\} . \tag{65}
\end{array}
\]

The function has a saddle near \((1,1,1,1)\). The only minimum is located at \(x^{*}=(1,1,1,1)\) with \(f\left(x^{*}\right)=0\).

\section*{34. Levy and Montalvo 2 Problem}
\[
\begin{array}{cc}
\min _{x} f(x)=0.1\left(\sin ^{2}\left(3 \pi x_{1}\right)+\sum_{i=1}^{n-1}\left(x_{i}-1\right)^{2}\left[1+\sin ^{2}\left(3 \pi x_{i+1}\right]\right.\right. \\
& \left.+\left(x_{n}-1\right)^{2}\left[1+\sin ^{2}\left(2 \pi x_{n}\right)\right]\right) \\
\text { subject to } & -5 \leq x_{i} \leq 5, i \in\{1,2, \ldots, n\} . \tag{67}
\end{array}
\]

There are approximately \(15^{n}\) minima and the global minimizer is known to be \(x^{*}=(1,1, \ldots, 1)\) with \(f\left(x^{*}\right)=0\). Our tests were performed with \(n=5\) and 10 .

\section*{35. Salomon Problem}
\[
\begin{array}{cc}
\min _{x} f(x)= & 1-\cos (2 \pi\|x\|)+0.1\|x\| \\
\text { subject to } & -100 \leq x_{i} \leq 100 \tag{69}
\end{array}
\]
where \(\|x\|=\sqrt{\sum_{i=1}^{n} x_{i}^{2}}\). The number of local minima (as a function of \(n\) ) is not known, but the global minimizer is located at \(x^{*}=(0,0,0, \ldots, 0)\) with \(f\left(x^{*}\right)=0\). Our tests were performed with \(n=5\) and \(n=10\).

\section*{36. Shekel's Foxholes}
\[
\begin{array}{cc}
\min _{x} f(x)= & -\sum_{j=1}^{30} \frac{1}{c_{j}+\sum_{i=1}^{n}\left(x_{i}-a_{j i}\right)^{2}} \\
\text { subject to } & 0 \leq x_{i} \leq 10, i \in\{1,2, \ldots, 10\} \tag{71}
\end{array}
\]

Our tests were performed with \(n=5\) and 10 . The constants \(c_{j}\) and \(a_{j i}\) are given in Table 7 . The number of local minima is not known, but the global minima are presented in Table 8 .

\section*{37. Hartman 6 Problem}
\[
\begin{array}{cc}
\min _{x} f(x)= & -\sum_{i=1}^{4} c_{i} \exp \left[-\sum_{j=1}^{6} a_{i j}\left(x_{j}-p_{i j}\right)^{2}\right] \\
\text { subject to } & -0 \leq x_{j} \leq 1, j \in\{1, \ldots, 6\} \tag{73}
\end{array}
\]
with constants \(a_{i j}\) and \(c_{i}\) given in Table 9 and constants \(p_{i j}\) in Table 10. There are four local minima, \(x_{\text {local }} \approx\left(p_{i 1}, \ldots, p_{i 6}\right)\) with \(f\left(x_{\text {local }}\right) \approx-c_{i}\). The global minimum is located at \(x^{*} \approx(0.201690,0.150011,0.476874,0.275332,0.311652,0.657301)\) with \(f\left(x^{*}\right) \approx-3.322368\).

Table 7: Data for Shekel's foxholes problem
\begin{tabular}{rrrrrrrrrrrr}
\hline\(j\) & \multicolumn{11}{c}{\(c_{j i}\)} \\

\section*{38. Storn's Tchebychev Problem}
\[
\begin{equation*}
\min _{x} f(x)=p_{1}+p_{2}+p_{3} \tag{74}
\end{equation*}
\]
where
\[
\begin{aligned}
& p_{1}=\left\{\begin{array}{cl}
(u-d)^{2} & \text { if } u<d \\
0 & \text { if } u \geq d
\end{array}\right. \\
& p_{2}=\left\{\begin{array}{cl}
(v-d)^{2} & \text { if } v<d \\
0 & \text { if } v \geq d
\end{array}\right. \\
& p_{3}=\sum_{j=0}^{m} \begin{cases}\left(w_{j}-1\right)^{2} & \text { if } w_{j}>1 \\
\left(w_{j}+1\right)^{2} & \text { if } w_{j}<-1 \\
0 & \text { if }-1 \leq w_{j} \leq 1\end{cases} \\
& \begin{array}{ll}
n=\sum_{i=1}^{n}(-1.2)^{n-i} x_{i}
\end{array} \\
& \text { for } n=9: \quad x_{j}=\sum_{i=1}^{n}\left(\frac{2 j}{m}-1\right)^{n-i} x_{i}, \\
& \text { for } n=17: \\
& x_{i} \in[-32768,32768]^{n}, d=10558.145, \text { and } m=100 .
\end{aligned}
\]

The number of local minima is not known but the global minimum is known to be as shown in Table 11. Our tests were performed with \(n=9\).

Table 11: Global optimizers for Storn's Tchebychev problem
\begin{tabular}{rrl}
\hline\(n\) & \(f\left(x^{*}\right)\) & \(x^{*}\) \\
\hline 9 & 0 & \((128,0,-256,0,160,0,-32,0,1)\) \\
17 & 0 & \((32768,0,-1331072,0,21299,0,-180224,84480,0,-2154,0,2688,0,-128,0,1)\) \\
\hline
\end{tabular}

\section*{39. Ackley's Problem}
\[
\begin{array}{cc}
\min _{x} f(x)= & -20 \exp \left(-0.2 \sqrt{\frac{1}{n} \sum_{i=1}^{n} x_{i}^{2}}\right)-\exp \left(\frac{1}{n} \sum_{i=1}^{n} \cos \left(2 \pi x_{i}\right)\right) \\
\quad+20+e & \\
\text { subject to } & -30 \leq x_{i} \leq 30, i \in\{1,2, \ldots, n\} \tag{76}
\end{array}
\]

The number of local minima is not known. The global minimum is located at the origin with \(f\left(x^{*}\right)=0\). Tests were performed for \(n=10\).

\section*{40. Exponential Problem}
\[
\begin{array}{cc}
\max _{x} f(x)= & \exp \left(-0.5 \sum_{i=1}^{n} x_{i}^{2}\right) \\
\text { subject to } & -1 \leq x_{i} \leq 1, i \in\{1,2, \ldots, n\} \tag{78}
\end{array}
\]

The optimal value \(f\left(x^{*}\right)=1\) is located at the origin. Our tests were performed with \(n=10\).

\section*{41. Griewangk Problem}
\[
\begin{array}{cl}
\min _{x} f(x)= & 1+\frac{1}{4000} \sum_{i=1}^{n} x_{i}^{2}-\prod_{i=1}^{n} \cos \left(\frac{x_{i}}{\sqrt{i}}\right) \\
\text { subject to } & -600 \leq x_{i} \leq 600, i \in\{1,2, \ldots, n\} . \tag{80}
\end{array}
\]

The function has a global minimum located at \(x^{*}=(0,0, \ldots, 0)\) with \(f\left(x^{*}\right)=0\). Number of local minima for arbitrary \(n\) is unknown, but in the two dimensional case there are some 500 local minima. Tests were performed for \(n=10\).

\section*{42. Levy and Montalvo 2 Problem}

Same as problem number 34 , but tests were performed with \(n=10\).

\section*{43. Langerman 2 Problem}
\[
\begin{array}{cc}
\min _{x} f(x)= & -\sum_{j=1}^{5} c_{j} \cos \left(\pi d_{j}\right) \exp \left(-d_{j} / \pi\right), \\
\text { subject to } & 0 \leq x_{i} \leq 10, i \in\{1,2, \ldots, n\}, \tag{82}
\end{array}
\]
where \(d_{j}=\sum_{i=1}^{n}\left(x_{i}-a_{j i}\right)^{2}\). The test used \(n=10\). The constants \(c_{j}\) and \(a_{j i}\) are given in Table 12. Dimension of problem is 2 . The global minimum located at \(f\left(x^{*}\right)=-1.08\)

Table 12: Data for modified Langerman problem
\begin{tabular}{lrrrrrrrrrrr}
\hline\(j\) & \(c_{j} c_{j}\) & \multicolumn{10}{c}{\(a_{j i}\)} \\
\cline { 3 - 14 } & & \(i=1\) & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 \\
\hline 1 & 0.806 & 9.681 & 0.667 & 4.783 & 9.095 & 3.517 & 9.325 & 6.544 & 0.211 & 5.122 & 2.020 \\
2 & 0.517 & 9.400 & 2.041 & 3.788 & 7.931 & 2.882 & 2.672 & 3.568 & 1.284 & 7.033 & 7.374 \\
3 & 0.100 & 8.025 & 9.152 & 5.114 & 7.621 & 4.564 & 4.711 & 2.996 & 6.126 & 0.734 & 4.982 \\
4 & 0.908 & 2.196 & 0.415 & 5.649 & 6.979 & 9.510 & 9.166 & 6.304 & 6.054 & 9.377 & 1.426 \\
5 & 0.965 & 8.074 & 8.777 & 3.467 & 1.867 & 6.708 & 6.349 & 4.534 & 0.276 & 7.633 & 1.567 \\
\hline
\end{tabular}

\section*{44. Neumaier 3 Problem}
\[
\begin{array}{cc}
\min _{x} f(x)= & \sum_{i=1}^{n}\left(x_{i}-1\right)^{2}-\sum_{i=2}^{n} x_{i} x_{i-1} \\
\text { subject to } & -n^{2} \leq x_{i} \leq n^{2}, i \in\{1,2, \ldots, n\} . \tag{84}
\end{array}
\]

The case considered here is \(n=10\). The number of local minima is not known, but the global minima can be expressed as:
\[
f\left(x^{*}\right)=-\frac{n(n+4)(n-1)}{6}, \quad x_{i}^{*}=i(n+1-i) .
\]

The global minima for some values of \(n\) are presented below.
Table 13: Global minima for Neumaier 3 problem
\begin{tabular}{lrrrrr}
\hline\(n\) & 10 & 15 & 20 & 25 & 30 \\
\hline\(f\left(x^{*}\right)\) & -210 & -665 & -1520 & -2900 & -4930 \\
\hline
\end{tabular}

\section*{45. Paviani Problem}
\[
\begin{array}{cc}
\min _{x} f(x)=\sum_{i=1}^{10}\left[\left(\ln \left(x_{i}-2\right)\right)^{2}+\left(\ln \left(10-x_{i}\right)\right)^{2}\right]-\left(\prod_{i=1}^{10} x_{i}\right)^{0.2} \\
\text { subject to } & 2 \leq x_{i} \leq 10, i \in\{1,2, \ldots, 10\} . \tag{86}
\end{array}
\]

This function has a global minimizer at \(x_{i}^{*} \approx 9.351\) for all \(i\), with \(f\left(x^{*}\right) \approx-45.778\).

\section*{46. Rastrigin Problem}
\[
\begin{array}{cc}
\min _{x} f(x)= & 10 n+\sum_{i=1}^{n}\left[x_{i}^{2}-10 \cos \left(2 \pi x_{i}\right)\right] \\
\text { subject to } & -5.12 \leq x_{i} \leq 5.12, i \in\{1,2, \ldots, n\} \tag{88}
\end{array}
\]

The total number of minima for this function is not exactly known but the global minimizer is located at \(x^{*}=(0,0, \ldots, 0)\) with \(f\left(x^{*}\right)=0\). For \(n=2\), there are about 50 local minimizers arranged in a lattice like configuration. Our tests were performed with \(n=10\).

\section*{47. Rosenbrock Problem}
\[
\begin{array}{cc}
\min _{x} f(x)= & \sum_{i=1}^{n-1}\left[100\left(x_{i+1}-x_{i}^{2}\right)^{2}+\left(x_{i}-1\right)^{2}\right] \\
\text { subject to } & -30 \leq x_{i} \leq 30, i \in\{1,2, \ldots, n\} . \tag{90}
\end{array}
\]

Our tests were performed with \(n=10\). This function is known as the extended Rosenbrock function. It is unimodal, yet due to a saddle point it is very difficult to locate the minimizer \(x^{*}=(1,1, \ldots, 1)\) with \(f\left(x^{*}\right)=0\).

\section*{48. Salomon Problem}

Same as problem number 35 , but tests were performed with \(n=10\).

\section*{49. Schwefel Problem}
\[
\begin{array}{cc}
\min _{x} f(x)= & -\sum_{i=1}^{n} x_{i} \sin \left(\sqrt{\left|x_{i}\right|}\right) \\
\text { subject to } & -500 \leq x_{i} \leq 500, i \in\{1,2, \ldots, n\} . \tag{92}
\end{array}
\]

The number of local minima for a given \(n\) is not known, but the global minimum value \(f\left(x^{*}\right) \approx-418.9829 n\) is located at \(x^{*}=(s, s, \ldots, s), s \approx 420.97\). Our tests were performed with \(n=10\).

\section*{50. Shekel's Foxholes}

Same as problem number 36 , but tests were performed with \(n=10\).

\section*{51. Sinusoidal Problem}
\[
\begin{array}{cc}
\min _{x} f(x)=-\left[A \prod_{i=1}^{n} \sin \left(x_{i}-z\right)+\prod_{i=1}^{n} \sin \left(B\left(x_{i}-z\right)\right)\right] \\
\text { subject to } & 0 \leq x_{i} \leq 180, i \in\{1,2, \ldots, n\} . \tag{94}
\end{array}
\]

The variable \(x\) is in degrees. Parameter \(A\) affects the amplitude of the global optimum; \(B\) affects the periodicity and hence the number of local minima; \(z\) shifts the location of the global minimum; and \(n\) indicates the dimension. Our tests were performed with \(A=2.5, B=\) \(5, z=30\), and \(n=10\) and 20. The location of the global solution is at \(x^{*}=(90+z, 90+\) \(z, \ldots, 90+z)\) with the global optimum value of \(f\left(x^{*}\right)=-(A+1)\). The number of local minima increases dramatically in dimension, and when \(B=5\) the number of local minima is equal to:
\[
\begin{equation*}
\sum_{i=0}^{\lfloor n / 2\rfloor}\left(\frac{n!}{(n-2 i)!(2 i)!} 3^{n-2 i} 2^{2 i}\right) . \tag{95}
\end{equation*}
\]

\section*{52. Sphere Problem}
\[
\begin{array}{cc}
\min _{x} f(x)= & \sum_{i=1}^{n} x_{i}^{2} \\
\text { subject to } & -100 \leq x_{i} \leq 100, i \in\{1,2, \ldots, n\} . \tag{97}
\end{array}
\]

A very simple unimodal function with its global minimum located at \(x^{*}=0\), with \(f\left(x^{*}\right)=0\). This function has no interaction between its variables.

\section*{53. Storn's Tchebychev Problem}

Same as problem number 38 , but tests were performed with \(n=17\).

\section*{54. Sinusoidal Problem}

Same as problem number 51, but tests were performed with \(n=20\).

\section*{55. Step Problem}
\[
\begin{array}{cc}
\min _{x} f(x)= & \sum_{i=1}^{n}\left(\left\lfloor x_{i}+0.5\right\rfloor\right)^{2} \\
\text { subject to } & -100 \leq x_{i} \leq 100, i \in\{1,2, \ldots, n\} \tag{99}
\end{array}
\]

The global minimal is located \(x^{*}=f(0.5, \ldots, 0.5)=0, f\left(x^{*}\right)=0\).
56. StepInt Problem
\[
\begin{array}{cc}
\min _{x} f(x)= & 25+\sum_{i=1}^{5}\left\lfloor x_{i}\right\rfloor \\
\text { subject to } & -5.12 \leq x_{i} \leq 5.12, i \in\{1,2, \ldots, n\} . \tag{101}
\end{array}
\]

The global minimal is located \(x^{*}=f(0, \ldots, 0)=0, f\left(x^{*}\right)=0\).

\section*{57. Sum Squares Problem}
\[
\begin{array}{cc}
\min _{x} f(x)= & \sum_{i=1}^{n} i x_{i}^{2} \\
\text { subject to } & -10 \leq x_{i} \leq 10, i \in\{1,2, \ldots, n\} \tag{103}
\end{array}
\]

The global minimal is located \(x^{*}=f(0, \ldots, 0)=0, f\left(x^{*}\right)=0\).
58. Trid 6 Problem
\[
\begin{array}{lc}
\min _{x} f(x)= & \sum_{i=1}^{n}\left(x_{i}-1\right)^{2}-\sum_{i=2}^{n} x_{i} x_{i-1} \\
\text { subject to } & -6^{2} \leq x_{i} \leq 6^{2}, i \in\{1,2, \ldots, n\} . \tag{105}
\end{array}
\]

The global minimal is located \(f\left(x^{*}\right)=-50\).
59. Trid 10 Problem
\[
\begin{array}{cc}
\min _{x} f(x)= & \sum_{i=1}^{n}\left(x_{i}-1\right)^{2}-\sum_{i=2}^{n} x_{i} x_{i-1} \\
\text { subject to } & -100 \leq x_{i} \leq 100, i \in\{1,2, \ldots, n\} . \tag{107}
\end{array}
\]

The global minimal is located \(f\left(x^{*}\right)=-200\).
60. Zakharov Problem
\[
\begin{array}{cc}
\min _{x} f(x)= & \sum_{i=1}^{n}\left(x_{i}\right)^{2}+\left(\sum_{i=1}^{n} 0.5 i x_{i}\right)^{2}+\left(\sum_{i=1}^{n} 0.5 i x_{i}\right)^{4} \\
\text { subject to } & -5 \leq x_{i} \leq 10, i \in\{1,2, \ldots, n\} . \tag{109}
\end{array}
\]

The global minimal is located \(x^{*}=f(0, \ldots, 0)=0, f\left(x^{*}\right)=0\).

\section*{61. Matyas Problem}
\[
\begin{array}{cc}
\min _{x} f(x)= & 0.26\left(x_{1}+x_{2}\right)-0.48 x_{1} x_{2} \\
\text { subject to } & -10 \leq x_{i} \leq 10, i \in\{1,2, \ldots, n\} . \tag{111}
\end{array}
\]

The global minimal is located at \(x^{*}=f(0, \ldots, 0)=0, f\left(x^{*}\right)=0\).
62. Epistatic Michalewicz 2 Problem
\[
\begin{gather*}
\min _{x} f(x)=-\sum_{i=1}^{n} \sin \left(y_{i}\right)\left(\sin \left(i y_{i}^{2} / \pi\right)\right)^{2 m}  \tag{112}\\
\text { subject to } 0 \leq x_{i} \leq \pi, i \in\{1,2, \ldots, n\} .  \tag{113}\\
y_{i}=\left\{\begin{array}{c}
x_{i} \cos (\theta)-x_{i+1} \sin (\theta), i=1,3,5, \ldots, \leq n \\
x_{i} \sin (\theta)-x_{i+1} \cos (\theta), i=2,4,6, \ldots, \leq n \\
x_{i}, i=n
\end{array}\right. \\
\theta=\pi / 6, m=10 \text { The global minimal is located at } f\left(x^{*}\right)=-1.8013 .
\end{gather*}
\]

\section*{63. Quadric Problem}
\[
\begin{array}{cc}
\min _{x} f(x)= & \sum_{i=1}^{n}\left(\sum_{j=1}^{i} x_{j}\right)^{2} \\
\text { subject to } & -100 \leq x_{i} \leq 100, i \in\{1,2, \ldots, n\} \tag{115}
\end{array}
\]

The global minimal is located at \(x^{*}=f(0, \ldots, 0)=0, f\left(x^{*}\right)=0\).

\section*{64. Chung Reynolds Problem}
\[
\begin{array}{cc}
\min _{x} f(x)= & x_{1}^{2}+2 x_{2}^{2}-0.3 \cos \left(3 \pi x_{1}+4 \pi x_{2}\right)+0.3 \\
\text { subject to } & -100 \leq x_{i} \leq 100, i \in\{1,2, \ldots, n\} \tag{117}
\end{array}
\]

The global minimal is located at \(x^{*}=f(0, \ldots, 0)=0, f\left(x^{*}\right)=0\).

\section*{65. Bohachevsky 3 Problem}
\[
\begin{array}{cc}
\min _{x} f(x)= & x_{1}^{2}+2 x_{2}^{2}-0.3 \cos \left(3 \pi x_{1}+4 \pi x_{2}\right)+0.3 \\
\text { subject to } & -100 \leq x_{i} \leq 100, i \in\{1,2, \ldots, n\} \tag{119}
\end{array}
\]

The global minimal is located at \(x^{*}=f(0, \ldots, 0)=0, f\left(x^{*}\right)=0\).

\section*{66. Langermann 5 Problem}

Same as problem number 43, dimension of problem is 5 . The global minimum located at \(f\left(x^{*}\right)=-1.5\)

\section*{67. Langermann 10 Problem}

Same as problem number 43 and 66, dimension of problem is 10 . The global minimum located at \(f\left(x^{*}\right)=N A\)

\section*{68. Dixcon-Price Problem}
\[
\begin{align*}
\min _{x} f(x)= & \left(x_{1}-1\right)^{2}+\sum_{i=2}^{n} i\left(2 x_{i}^{2}-x_{i-1}\right)^{2}  \tag{120}\\
\text { subject to } & -10 \leq x_{i} \leq 10, i \in\{1,2, \ldots, n\} . \tag{121}
\end{align*}
\]

The global minimal is located at \(x^{*}=f(0, \ldots, 0)=0, f\left(x^{*}\right)=0\).

\section*{69. Beale Problem}
\[
\begin{gather*}
\min _{x} f(x)=\left(1.5-x_{1}+x_{1} x_{2}\right)^{2}+\left(2.25-x_{1}+x_{1}+x_{1} x_{2}^{2}\right)^{2}+  \tag{122}\\
\left(2.625-x_{1}+x_{1}+x_{1} x_{2}^{3}\right)^{2} \tag{123}
\end{gather*}
\]
subject to
\[
-4.5 \leq x_{i} \leq 4.5
\]

The global minimal is located at \(f\left(x^{*}\right)=0\).

\section*{70. Epistatic Michalewicz 5 Problem}

Same as 62 but dimension is 5 . The global minimal is located at \(f\left(x^{*}\right)=-4.687658\).

\section*{71. Foxholes Problem}
\[
\begin{array}{ll}
\min _{x} f(x)= & {\left[\begin{array}{c}
\frac{1}{500}+\sum_{j=1}^{25} \frac{1}{j+\sum_{i=1}^{2}\left(x_{i}-a_{i j}\right) 6}
\end{array}\right]^{-1}}  \tag{126}\\
\text { subject to } & -65.536 \leq x_{i} \leq 65.536 .
\end{array}
\]

The global minimal is located at \(f\left(x^{*}\right)=0.998\). Data for \(a_{i j}\) is in table 14

\section*{72. Booth Problem}
\[
\begin{array}{cl}
\min _{x} f(x)= & \left(x_{1}+2 x_{2}-7\right)^{2}+\left(2 x_{1}+x_{2}-5\right)^{2} \\
\text { subject to } & -10 \leq x_{i} \leq 10, i \in\{1,2, \ldots, n\} \tag{130}
\end{array}
\]

The global minimal is located at \(x^{*}=f(0, \ldots, 0)=0, f\left(x^{*}\right)=0\).

\section*{73. Colville Problem}
\[
\begin{aligned}
& \min _{x} f(x)=100\left(x_{1}^{2}-x_{2}^{2}\right)^{2}+\left(x_{1}-1\right)^{2}+\left(x_{3}-1\right)^{2}+90\left(x_{3}^{2}-x_{4}\right)^{2}+10.1\left(x_{2}-1\right)^{2}+\left(x_{4}-1\right)^{2}+19.8\left(x_{2}-1\right. \\
& \text { subject to }-10 \leq x_{i} \leq 10, i \in\{1,2, \ldots, n\}
\end{aligned}
\]

The global minimal is located at \(x^{*}=f(0, \ldots, 0)=0, f\left(x^{*}\right)=0\).

\section*{74. Odd Square Problem}
