

20 **Abstract**

21 This study conducted the global sensitivity analysis of the APSIM-Oryza rice growth
22 model under eight climate conditions and two CO₂ levels using the extended Fourier
23 Amplitude Sensitivity Test method. Two output variables (i.e. total aboveground dry
24 matter WAGT and dry weight of storage organs WSO) and twenty parameters were
25 analyzed. The $\pm 30\%$ and $\pm 50\%$ perturbations of base values were used as the ranges
26 of parameter variation, and local fertilization and irrigation managements were
27 considered. Results showed that the influential parameters were the same under
28 different environmental conditions, but their orders were often different. Climate
29 conditions had obvious influence on the sensitivity index of several parameters (e.g.
30 RGRLMX, WGRMX and SPGF). In particular, the sensitivity index of RGRLMX
31 was larger under cold climate than under warm climate. Differences also exist for
32 parameter sensitivity of early and late rice in the same site. The CO₂ concentration
33 did not have much influence on the results of sensitivity analysis. The range of
34 parameter variation affected the stability of sensitivity analysis results, but the main
35 conclusions were consistent between the results obtained from the $\pm 30\%$ perturbation
36 and those obtained the $\pm 50\%$ perturbation in this study. Compared with existing
37 studies, our study performed the sensitivity analysis of APSIM-Oryza under more
38 environmental conditions, thereby providing more comprehensive insights into the
39 model and its parameters.

43 **1. Introduction**

44 Crop growth models have been widely used in many applications such as crop
45 management, climate change assessment, and yield gap analysis (Holzworth et al.,
46 2015; Lobell et al., 2015; Müller et al., 2017; Tao et al., 2018). Prior to the application
47 of crop growth models, their parameters must be determined properly. As some
48 parameters are hard to measure directly, parameter calibration using optimization
49 algorithms is usually needed (Archontoulis et al., 2014; Kamali et al., 2018).

50

51 Parameter calibration needs to run a crop model many times in order to evaluate the
52 simulation performance under different parameter combinations. The number of
53 model runs is in proportion to the complexity of the model and the number of
54 parameters (Zhao et al., 2014). If many parameters are involved in the calibration, a
55 large number of model runs is needed. In this case, parameter calibration will take a
56 long computation time. In order to reduce the number of parameters used in
57 calibration, sensitivity analysis was introduced to determine those most influential
58 parameters (Lamboni et al., 2009; Zadeh et al., 2017). The results of parameter
59 sensitivity analysis can also be used to dissect the robustness of simulation methods
60 and the balance of different components in the model, which can provide valuable
61 information on the application and improvement of models (Cariboni et al., 2007;
62 Confalonieri et al., 2010b; Wang et al., 2013).

63

64 The methods for parameter sensitivity analysis can be broadly divided into two
65 classes: local methods and global methods (Saltelli et al., 2000). The local methods
66 (e.g. simple derivative-based method) explore the responses of output variables to
67 parameter changes by varying one parameter at each time while holding the other
68 parameters fixed (Cariboni et al., 2007). They are easy to implement and have low
69 computational cost, but their results heavily depend on parameter's base value and
70 cannot capture the interactions among parameters. In contrast, the global sensitivity
71 analysis methods overcome the shortcomings of the local methods by simultaneously
72 exploring the whole multi-dimensional parameter space, and therefore can the give a

73 more comprehensive view of the sensitivity of model output to parameters
74 (Confalonieri et al., 2010a; Yang, 2011). The widely used global sensitivity analysis
75 methods include screening-based methods such as Morris (Morris, 1991),
76 regression-based methods such as Latin hypercube sampling (Helton et al., 2005), and
77 variance-based methods such as Sobol' (Sobol, 1993) and extended Fourier
78 Amplitude Sensitivity Test (extended FAST) (Saltelli et al., 1999).

79
80 Numerous global sensitivity analysis methods have been applied to different crop
81 models (DeJonge et al., 2012; Kamali et al., 2018; Lamboni et al., 2009; Saltelli et al.,
82 1999; Sexton et al., 2017; Zadeh et al., 2017). For example, DeJonge et al. (2012)
83 conducted parameter sensitivity analysis for the CERES-Maize model using Morris
84 and Sobol' global sensitivity analysis methods. Wang et al. (2013) applied the
85 extended FAST method to the WO^rld FO^od STudies (WOFOST) crop growth model.
86 These studies provided valuable information for the calibration and application of
87 crop models.

88
89 APSIM-Oryza is a model for rice growth simulation, and it has been increasingly used
90 in related studies because of the widely-accepted APSIM (Agricultural Production
91 Systems sIMulator) platform (Amarasingha et al., 2015; Gaydon et al., 2012; Gaydon
92 et al., 2017; Holzworth et al., 2014; Radanielson et al., 2018; Zhang et al., 2007). The
93 crop growth process of APSIM-Oryza was borrowed from the Oryza2000 model
94 (<https://sites.google.com/a/irri.org/oryza2000/>, Bouman et al., 2001; Bouman and Van
95 Laar, 2006; Li et al., 2017). Although there existed some studies on the parameter
96 sensitivity analysis of Oryza2000 and ORYZA_V3 (Soundharajan and Sudheer, 2013;
97 Tan et al., 2016; Tan et al., 2017), these studies were all conducted at a single point.
98 Because the sensitivity of model outputs to parameters can be influenced by
99 environment conditions (Confalonieri et al., 2010b; DeJonge et al., 2012; Zhao et al.,
100 2014), it is necessary to conduct sensitivity analysis of the APSIM-Oryza model under
101 different environment conditions in order to obtain a comprehensive view of the
102 sensitivity of model outputs to parameters, which is the objective of this study. In

103 addition, because of the interaction between the APSIM platform and its Oryza
104 module, the sensitivity analysis results of APSIM-Oryza may not be exactly the same
105 as the original ORYZA model (Bouman et al., 2001; Li et al., 2017).

106

107 In this study, six sites in different regions over China and two levels of CO₂
108 concentrations were used for the sensitivity analysis. This study aims to explore
109 whether and to what extent the sensitivity of model outputs to parameters varies under
110 different environmental conditions.

111

112 **2. Methods**

113 **2.1 APSIM-Oryza**

114 APSIM is a flexible modeling framework for agricultural system, which has many
115 modules for different crops (Brown et al., 2014; Holzworth et al., 2014). The key
116 concept in the design of APSIM is a focus on cropping systems rather than individual
117 crops. The dynamics of soil plays an important role in APSIM as McCown et al.
118 (1995 stated that “*Crops come and go, each finding the soil in a particular state and*
119 *leaving it in an altered state.*” A specific crop module can be incorporated to the
120 framework via a plug-in mechanism.

121

122 The ‘Rice’ module in APSIM (APSIM-Oryza) simulates the rice growth under
123 potential production, water-limited and N-limited simulations at a daily time-step
124 (Gaydon et al., 2012; Gaydon et al., 2017; Zhang et al., 2007). APSIM-Oryza interacts
125 with other components of APSIM such as soil water, irrigation, and fertilization. The
126 main crop-growth processes include phenology, leaf area development, biomass
127 production and allocation. Development in APSIM-Oryza is represented by DVS
128 (development stage), which represents the plant’s physiological age (Bouman and Van
129 Laar, 2006). The key development stages of rice are emergence (DVS=0), the end of
130 juvenile stage (DVS=0.4), panicle initiation (DVS=0.65), flowering (DVS=1), and
131 physiological maturity (DVS=2) (Bouman et al., 2001). The parameters related to the
132 development of rice are mainly the changes in DVS per degree day (i.e. DVRJ, DVRI,

133 DVRP, and DVRR as shown in Table 1).

134 The daily CO₂ assimilation rate is calculated by integrating instantaneous assimilation
135 rates over time and depth within the canopy. The integration assumes sinusoidal time
136 course of radiation in the day and exponential light profile in the canopy. The net
137 daily growth rate in kg dry matter per ha per day can be obtained by subtracting
138 respiration requirements from the total assimilation rate. The produced dry matter is
139 partitioned among various organs (i.e. leaves, stems, panicles and roots). The
140 partitioning coefficients are determined experimentally according to the development
141 stage (Bouman et al., 2001; Li et al., 2017). The related parameters mainly include
142 FLV0.5, FLV0.75, FST1.0, DRLV1.0, DRLV2.1 and FSTR. The parameter names
143 such as FLV0.5 were the annexation of the parameter name (e.g. FLV) and the
144 development stage (e.g. 0.5). The parameter FLV0.5 means the fraction of shoot dry
145 matter partitioned to the leaves at DVS=0.5. The meanings of other parameters can be
146 found in Table 1.

147

148 The number of spikelets at flowering is proportional to the total biomass accumulated
149 from panicle initiation to flowering. The parameter SPGF (no./kg) is used to describe
150 the number of spikelets per unit mass of biomass. Some spikelets turn into grains with
151 crop growth, while some others become sterile because of too high or too low
152 temperature. The parameter WGRMX (kg/grain) is used to control the maximum
153 individual grain weight. For leaf area growth, when LAI (leaf area index) is less than
154 1, LAI increases exponentially as a function of temperature sum (°Cd). The parameter
155 RGRLMX and RGRLMN are used to calculate the relative leaf area growth rate (R_l
156 in Eq. 1 and Eq. 2, (°C d)⁻¹) in this exponential growth phase. R_l is then used to
157 calculate the growth in LAI ($gLAI$ in Eq. 2, ha leaf/ha soil/d). The related formulas are
158 described as follows:

$$159 \quad R_l = RGRLMX - (1 - f_N)(RGRLMX - RGRLMN) \quad (1)$$

$$160 \quad gLAI = LAI \times R_l \times HULV \quad (2)$$

161 where, f_N is the reduction factor for the relative leaf area growth rate caused by

162 nitrogen (N) limitation, *HULV* is the daily increase in temperature sum ($^{\circ}\text{Cd}/\text{d}$). When
163 LAI exceeds 1, LAI increases linearly with the amount of carbohydrates available for
164 leaf growth according to specific leaf area (SLA, m^2/kg). The parameters involved in
165 the calculation of SLA include ASLA, BSLA, CSLA, DSLA and SLAMAX. The
166 main outputs involved in the analysis include total aboveground dry matter (WAGT in
167 the model) and dry weight of storage organs or total panicle biomass (WSO in the
168 model). For cereals like rice, WSO is an indicator of grain yield and it is useful in
169 crop performance evaluation

171 Table 1. Description of selected parameters and output variables in the APSIM-Oryza model

| Name | Description | Unit | Lower bound (30%) ^a | Upper bound (30%) | Lower bound (50%) | Upper bound (50%) | Base value ^b |
|-------------------|---|-----------------------|-----------------------------------|----------------------|----------------------|----------------------|-------------------------|
| Parameters | | | | | | | |
| DVRJ | Development rate in juvenile phase | (°Cday) ⁻¹ | 0.0007 | 0.0013 | 0.0005 | 0.0015 | 0.001 |
| DVRI | Development rate in photoperiod-sensitive phase | (°Cday) ⁻¹ | 0.000525 | 0.000975 | 0.000375 | 0.001125 | 0.00075 |

| WSO | Dry weight of storage organs | kg/ha | | | | | |

172 ^a Lower bound means the base value minus 30% or 50%, upper bound means the base value plus %30 or 50%. ^b Base values are obtained from Tan et al.
173 (2016).

174

175

176 2.2 Global sensitivity analysis method

177 The extended FAST method, a variance-based global sensitivity analysis algorithm
178 (Saltelli et al., 1999), was used in this study. The core concept of variance-based
179 sensitivity analysis method is that the variance of a model output (Y) can be
180 decomposed as Eq. (3).

$$181 \quad V(Y) = \sum_{i=1}^n V_i + \sum_{1 \leq i < j \leq n} V_{ij} + \dots + V_{12\dots n} \quad (3)$$

182 where, $V(Y)$ denotes the total variance of model output Y , V_i denotes the variance
183 allocated to the i -th parameter P_i , and V_{ij} denotes the variance allocated to the
184 interaction between P_i and P_j . The sensitivity of output Y to P_i , called the main or
185 first-order index (S_i), is measured by the ratio of P_i -caused variance to total variance
186 $V(Y)$ (as shown in Eq. (4)).

$$187 \quad S_i = \frac{V_i}{V(Y)} \quad (4)$$

188 The total sensitivity index (ST_i) measures all the effects associated with parameter
189 P_i , including the main effect and the interactions with other parameters. It is
190 defined by Eq. (5):

$$191 \quad ST_i = S_i + \sum_{i \neq j} S_{ij} + \sum_{i \neq j \neq m} S_{ijm} + \dots + S_{12\dots n} = \frac{V(Y) - V_{-i}}{V(Y)} \quad (5)$$

192 S_{ij} denotes the second-order sensitivity index for the couple of parameter P_i and P_j ,
193 S_{ijm} denotes the third-order sensitivity index for the combination of Parameter P_i
194 and any other two parameters, and so on. V_{-i} denotes the sum of the contributions to
195 the variance of output that do not include parameter P_i .

196 The ranges of both S_i and ST_i are $[0, 1]$. The larger the index value is, the more
197 influence the parameter has. $ST_i = S_i$ means that P_i does not interact with other
198 parameters. If $ST_i = S_i$ for all parameters, the model is additive (linear). Besides the
199 normal parameters, a “dummy parameter” also appears in the results of sensitivity
200 analysis, which can be used to judge whether the sensitivity index of a parameter is
201 significantly different from zero. When sampling, the dummy parameter is treated

202 as normal parameters; when running the simulations, the dummy parameter is
203 ignored because it neither appears in the model nor affects the model in any other
204 way; when calculating the sensitivity index, dummy parameter is considered again.
205 Thus the dummy parameter should ideally have a sensitivity index of zero (Marino
206 et al., 2008). However, because of the aliasing and interference effects, the obtained
207 index of dummy parameter would be a small but non-zero value. If the sensitivity
208 index of a parameter is less than or equal to that of the dummy parameter, the
209 sensitivity index of this parameter can be considered to be not significantly
210 different from zero (Zadeh et al., 2017).

211

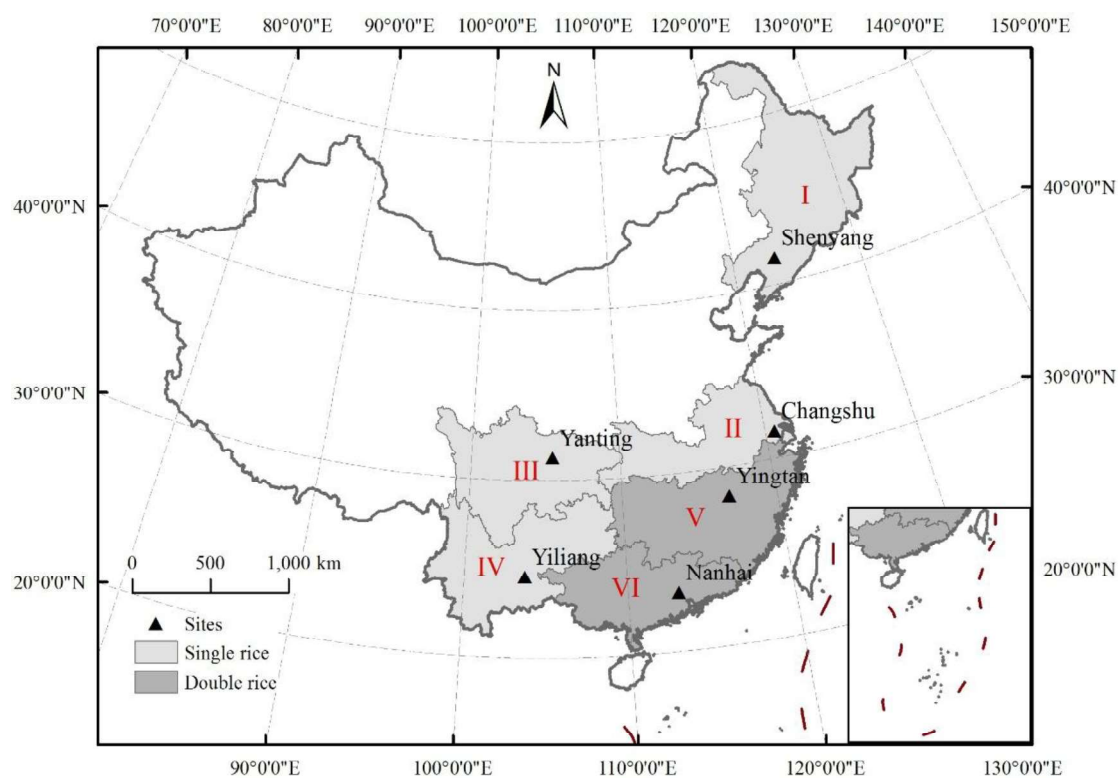

212 **2.3 Study sites and parameter settings**

213 There are six main cultivation regions of rice across mainland China; they include
214 single rice in Northeast China, single rice in mid-lower Yangtze River Valley, single
215 rice in Sichuan Basin, single rice in Yunnan-Guizhou Plateau, double rice in
216 mid-lower Yangtze River Valley, and double rice in South China (Sun and Huang,
217 2011). Six sites (Fig.1) were selected accordingly to study the effects of climate and
218 soil condition on the results of sensitivity analysis. Among these sites,
219 double-cropping rice is planted in Yingtan and Nanhai. The climate data, including
220 daily minimum and maximum air temperature, rainfall, and solar radiation from 1980
221 to 2010 were collected from CMA (China Meteorological Administration,
222 <http://data.cma.cn/>). For Shenyang, Changshu, Yanting, and Yingtan, the soil data and
223 management information (i.e. sowing date, transplanting date, fertilization and
224 irrigation operations) were obtained from CNERN (National Ecosystem Research
225 Network of China). For Yiliang and Nanhai, the soil data were obtained from China
226 Soil Database (<http://vdb3.soil.csdb.cn/>), and the management information was
227 obtained from the nearby agricultural meteorological stations of CMA
228 (http://data.cma.cn/data/cdcdetail/dataCode/AGME_AB2_CHN_TEN.html).

229

230 The fertilization rules for these six sites are described as follows: all sites were
231 fertilized one day after transplanting, and the other fertilization and corresponding

232 amounts depended on the management information. Taking the early rice in Yingtan
 233 site as an example, 86.5 kg/ha urea N was applied after transplanting (30 days after
 234 sowing). Besides, there were another time of fertilization (75.9 kg/ha urea N) after 40
 235 days of sowing. In Shenyang, because rice may reach maturity before the predefined
 236 fertilization date, the fertilization dates were first converted to DVS according to
 237 observed phenological phases and then DVS was used to control the fertilization dates
 238 in the simulation of this site. The maximum ponded water depth of the field was 60
 239 mm and irrigation was applied up to 30 mm of ponded water depth once the water
 240 depth dropped to zero. If the DVS was between 0.6 and 0.65 (the late tillering stage),
 241 there would be no irrigation in order to control inefficient tillers.

242
 243 Fig.1. The spatial distribution of six rice cultivation regions across mainland China
 244 and selected sites. The six rice cultivation regions are as following: I, single rice in
 245 Northeast China, II, single rice in mid-lower Yangtze River Valley, III, single rice in
 246 Sichuan Basin, IV, single rice in Yunnan-Guizhou Plateau, V, double rice in mid-lower
 247 Yangtze River Valley and VI, double rice in South China.

248

249 Table 2 presents the information of location, growing-season climate and topsoil

250 texture in the six selected sites. The growing-season climate values were calculated by
 251 averaging daily values between observed mean sowing dates to harvest dates. The
 252 climate data was from CMA and phenology data was from CNERN and agricultural
 253 meteorological stations. For Shenyang, Changshu, Yanting, and Yingtan, soil particle
 254 size in the top layer were obtained from CNERN. For Yiliang and Nanhai, soil
 255 particle size in the top layer were obtained from China Soil Database
 256 (<http://vdb3.soil.csdb.cn/>). During the growing season, the temperature in Shenyang
 257 and Yiliang were lower than other sites. The temperature in the growing season of late
 258 rice was higher than that of early rice and single rice. Shenyang had the highest daily
 259 solar radiation, and the early rice of Nanhai had the lowest one. Shenyang, Changshu
 260 and Yanting had less rainfall than other sites. The soil is mainly silt in Shenyang,
 261 Changshu and Nanhai, sand in Yanting, and clay in Yiliang.

262

263 Table 2. Location, growing-season climate and topsoil texture in the six selected sites.

| | Shenyang | Changshu | Yanting | Yiliang | Yingtan | Nanhai |
|---|-------------|-------------|-------------|-------------|--|-------------------------------|
| Rice type | Single rice | Single rice | Single rice | Single rice | Double rice | Double rice |
| Latitude | 41.52 | 31.55 | 31.27 | 24.53 | 28.25 | 23.13 |
| Longitude | 123.36 | 120.63 | 105.46 | 103.73 | 116.93 | 113.03 |
| Elevation(m) | 38 | 5 | 489 | 1699 | 41 | 1 |
| Mean daily temperature (°C) ^b | 20.30 | 25.95 | 25.04 | 20.09 | Early: 24.81 Late: 28.12 ^a | Early: 25.45 Late: 28.24 |
| Mean daily solar radiation(MJ/m ²) | 18.18 | 17.74 | 16.73 | 15.50 | Early: 16.74 Late: 17.17 | Early: 11.68 Late: 13.29 |
| Mean rainfall (mm) | 580.72 | 544.34 | 643.6 | 716.68 | Early: 1068.55 Late: 372.75 | Early: 855.73 Late: 452.53 |
| Sand (0.05-2.0mm) (%) ^c | 18.42 | 3.77 | 30.70 | 15.20 | 51.25 | 31.05 |
| Silt (0.002-0.05mm) (%) | 66.70 | 62.23 | 39.72 | 32.00 | 37.62 | 54.95 |
| Clay (<0.002mm) (%) | 14.88 | 34.00 | 20.14 | 52.80 | 11.13 | 14.00 |

264

265 ^a“Early” represents early rice, “Late” represents late rice. For example, “Late: 28.96” stands for
 266 the mean temperature of late rice in Yingtan is 28.12°C, etc.

267 ^b Mean daily temperature, mean daily solar radiation and mean rainfall are the mean value in rice
 268 growth period (from observed mean sowing date to harvesting date).

269 ^c Soil particle size in the top layer.

270

271 The sensitivity analysis in this study involved eight climate conditions, two CO₂

272 levels and twenty parameters. For single rice, each site corresponds to one type of
273 climate condition, and for double rice, each site corresponds to two types of climate
274 conditions (i.e. early rice and late rice). The double rice was simulated as two seasons
275 of single rice, and each season was configured with its own sowing and transplanting
276 dates. The number of search curves for extended FAST was set to five and the number
277 of samples per search curve was set to 97 according to existing researches (Marino et
278 al., 2008; Saltelli et al., 2000). So for a certain climate condition, CO₂ level, and
279 simulation period, the number of simulations was $5 \times (20+1) \times 97 = 10185$. The number
280 20 in the equation means 20 parameters and the number one means the one dummy
281 parameter. The parameter sampling strategy is the same as Saltelli et al. (1999).
282 Simulations were conducted for 31 years from 1980 to 2010. One result of parameter
283 sensitivity was calculated for each year, and the overall parameter sensitivity was
284 obtained by averaging each year's result.

285

286 The base values of parameters followed Tan et al. (2016), and the parameter values
287 for each simulation were generated randomly between the $\pm 30\%$ and $\pm 50\%$
288 perturbation of the base values. It should be noted that some parameter combinations
289 may lead to simulation failure for some site-years due to cold damage caused by low
290 temperature in late growth stage. Simulation failure here means that the simulated
291 value of WAGT or WSO is negative. Since negative WAGT or WSO values do not
292 make sense, thus we set negative WAGT or WSO to zero before the calculation of
293 sensitivity indices. In this study, when the $\pm 30\%$ perturbation was used, there was no
294 simulation failure. When the $\pm 50\%$ perturbation was used, there were a small number
295 of simulation failures mainly for the late rice in Yingtan and Naihui (Table A.1 in the
296 Appendix). The default CO₂ concentration used in simulation is 350 ppm. Because it
297 is widely acknowledged that the CO₂ concentration in atmosphere is increasing over
298 the past half century, two levels of CO₂ concentration (i.e. 350 ppm and 429 ppm)
299 were used to explore whether CO₂ concentration has effects on the sensitivity index
300 of parameters (Nakicenovic et al., 2000).

301

302 When the ranking of parameters is needed, ST_i was used as the criterion. For each
303 parameter, the ST_i values of multiple years in each climate condition were first
304 averaged, and then the ST_i values of different climate conditions were averaged to get
305 an overall ST_i for each parameter. A threshold of 0.05 for ST_i was used to select
306 influential parameters. In order to get the distribution of the simulation results, the
307 Kernel Density Estimate (KDE) method (Parzen, 1962) was adopted. KDE is a
308 nonparametric density estimator, which can learn the shape of the density from the
309 data automatically. In this study, we used the sns Python package to plot the KDE
310 curve, and the default settings of sns were used.

311

312 **3. Results**

313 **3.1 Overall parameter sensitivity under different environmental conditions**

314 **3.1.1 The sensitivity of total aboveground dry matter to parameters**

315 Fig. 2 shows the sensitivity indices under eight climate conditions for the output
316 variable WAGT at maturity for the $\pm 50\%$ perturbation of parameter's base value,
317 and the corresponding figure for the $\pm 30\%$ perturbation is shown in Fig. A.1 in the
318 Appendix. For both perturbations, the influential parameters (with overall ST_i larger
319 than 0.05) for all the sites were the same; they are the four development rate
320 parameters (DVRJ, DVRI, DVRP, DVRR) and three of the leaf relevant parameters:
321 parameter A of the function to calculate specific leaf area (ASLA), maximum relative
322 growth rate of leaf area (RGRLMX), and the fraction of shoot dry matter partitioned
323 to the leaves at DVS=0.5 (FLV0.5). The sensitivity indices of these parameters were
324 much larger than those of dummy parameter, indicating that they were significantly
325 different from zero. Other parameters showed little impacts on WAGT. The
326 interaction indices (the blue bar in Fig.2) were low for all climate conditions except
327 for Shenyang, suggesting that the interaction among parameters was weak. This
328 means that the parameters affect WAGT independently, only with slight interaction
329 with each other.

330

331 Fig.2. The main (Si) and total (STi) sensitivity indices under eight climate conditions
 332 for the output variable WAGT (total aboveground dry matter) at maturity for the $\pm 50\%$
 333 perturbation of parameter's base value. The title of each subfigure in the top of the
 334 figure means different environmental conditions. For example, "Shenyang" means
 335 single rice in the Shenyang site, "Yingtan_Early" means early rice in the Yingtan site,
 336 etc.

337

338 The sensitivity index of RGRLMX had obvious variation among different
 339 environmental conditions. For the $\pm 50\%$ perturbation, the STi value of RGRLMX
 340 for Yiliang was 0.38, while those for Yingtan_Late and Nanhai_Late were less than
 341 0.1. For double-rice sites, the overall sensitivity index of parameters was similar for
 342 early and late rices. However, there were also observable differences for the parameter
 343 DVRJ and RGRLMX. The sensitivity index of DVRJ for early rice was consistently
 344 smaller than that for late rice, while the sensitivity index of RGRLMX for early rice
 345 was larger than that of late rice.

346

347 3.1.2 The sensitivity of dry weight of storage organs to parameters

348 Dry weight of storage organs (WSO) is an indicator of grain yield in the
 349 APSIM-Oryza model (Bouman et al., 2001; Gaydon et al., 2012). Fig.3 shows the
 350 sensitivity indices under eight climate conditions for the output variable WSO for the
 351 $\pm 50\%$ perturbation of base values, and the corresponding figure for the $\pm 30\%$

352 perturbation was shown in Fig. A.2. For both perturbations, WSO were mainly
 353 sensitive to eight parameters (with overall ST_i larger than 0.05): the four development
 354 rates (DVRJ, DVRI, DVRP and DVRR), two leaf relevant parameters RGRLMX and
 355 ASLA, two grain relevant SPFG and WRGMX. The sensitivity indices of these
 356 parameters were much larger than those of dummy parameter, indicating they were
 357 significantly different from zero. The first six were also sensitive parameters for
 358 WAGT. Four development rates (DVRJ, DVRI, DVRP and DVRR) still dominated,
 359 although their relative importance was often different. The sensitivity of WSO to
 360 RGRLMX was weaker than that of WAGT in all sites except the Yiliang site.
 361 Compared with WAGT, WSO showed greater parameter interaction. The interaction
 362 part even accounted for over half of the total sensitivity indices for some parameters
 363 (e.g. development rates of the single rice in Shenyang, Yiliang and the early rice in
 364 Yingtan). This is because that the accumulation of storage organs was the last growth
 365 stage of rice and thus determined by the combined influence of many parameters. The
 366 sensitivity index of RGRLMX, WGRMX, and SPGF showed obvious variation
 367 among different environmental conditions. In particular, the sensitivity index of
 368 RGRLMX was much larger in Yiliang than in other sites.

369

370

371 Fig.3. The main (Si) and total (STi) sensitivity indices under eight climate conditions
 372 for the output variable WSO (dry weight of storage organs) at maturity for the $\pm 50\%$
 373 perturbation of parameter's base value. The title of each subfigure in the top of the

374 figure means different environmental conditions. For example, “Shenyang” means
375 single rice in the Shenyang site, “Yingtang_Early” means early rice in the Yingtang site,
376 etc.

377

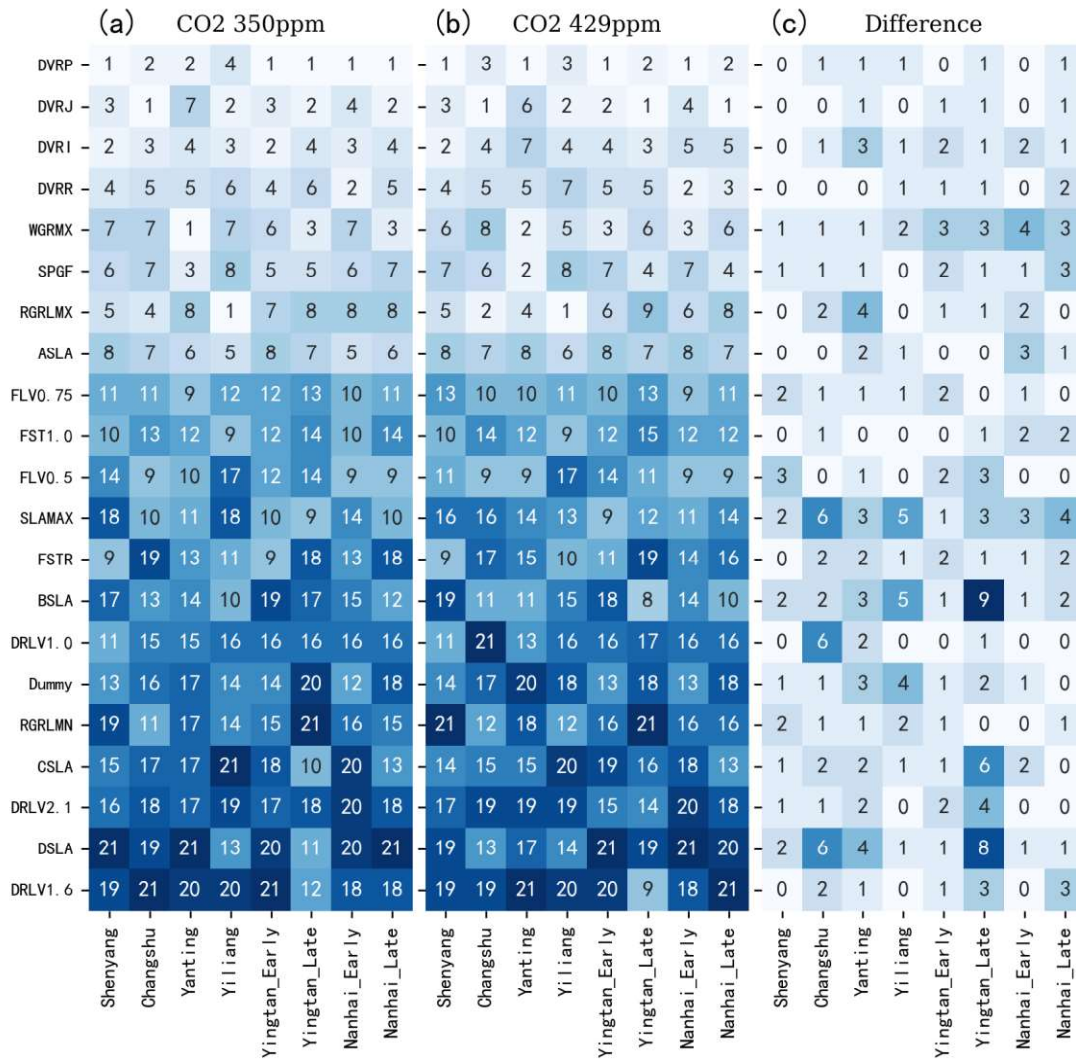

378 **3.2 Impacts of CO₂ concentration on parameter sensitivity**

379 Two levels of CO₂ concentrations (350ppm and 429ppm) were used to drive the
380 simulations under eight climate conditions, and the order of parameters was ranked by
381 the total sensitivity index (STi) for each level. The changes of orders in absolute value
382 under the two levels were then calculated to indicate the impact of CO₂ concentration
383 on the parameter sensitivity. Fig.4 and Fig.5 show the results for WAGT and WSO for
384 the $\pm 50\%$ perturbation of parameter's base value, respectively, and the
385 corresponding figures for the $\pm 30\%$ perturbation were shown in Fig. A.3 and Fig.
386 A.4 in the Appendix. For the influential parameters for the output variable WAGT
387 identified in Section 3.1 (i.e. DVRJ, DVRI, DVRP, DVRR, RGRLMX, ASLA, and
388 FLV0.5), the changes under two CO₂ concentration levels were slight. For the $\pm 50\%$
389 perturbation, only 2 out of the 56 changes were two, and the others (96%) were less
390 than or equal to one. For the influential parameters for the output variable WSO (i.e.
391 DVRJ, DVRI, DVRP, DVRR, RGRLMX, ASLA, WGRMX and SPGF), the changes
392 of orders were larger than those of WAGT. But there were still 75% of the changes
393 that were less than or equal to one. For the relatively insensitive parameters, the
394 changes of orders were sometimes large, but these parameters would not be used in
395 the model calibration, so these changes were not important. Overall, the CO₂
396 concentration did not have much influence on the results of sensitivity analysis for the
397 two output variables WAGT and WSO.

398

399 Fig.4. Impact of CO2 concentration on parameter sensitivity for WAGT (total
 400 aboveground dry matter) at maturity for the $\pm 50\%$ perturbation of parameter's base
 401 value. The numbers in Fig. (a) and (b) represent the order of parameters ranked by the
 402 total sensitivity index (STi) under two CO2 concentrations levels (i.e. 350ppm and
 403 429ppm), and the numbers in Fig. (c) represent the changes of orders in absolute
 404 value under these two levels.

405

406 Fig.5. Impact of CO₂ concentration on the parameter sensitivity for WSO (dry weight
 407 of storage organs) at maturity for the $\pm 50\%$ perturbation of parameter's base value.

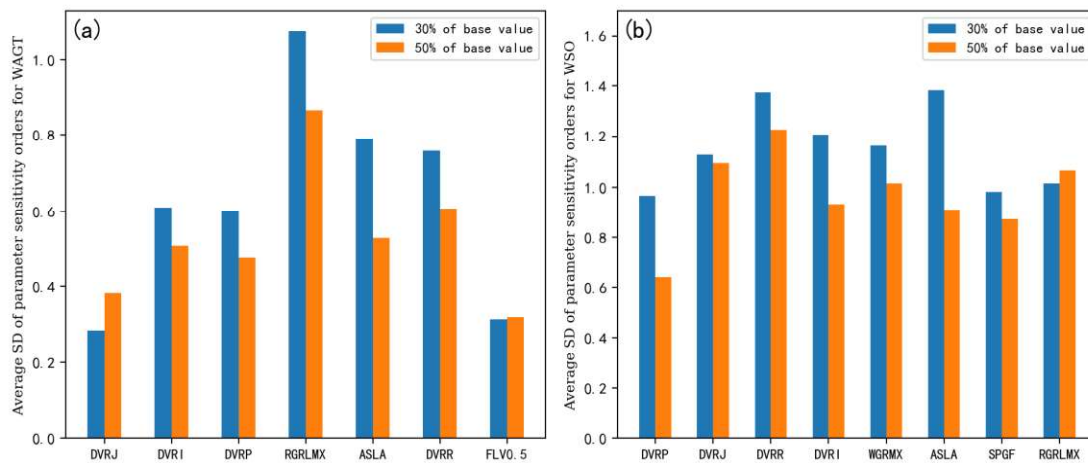

408 The numbers in Fig. (a) and (b) represent the order of parameters ranked by the total
 409 sensitivity index (ST_i) under two CO₂ concentrations levels (350ppm and 429ppm),
 410 and the numbers in Fig. (c) represent the changes of orders in absolute value under
 411 these two levels.

412

413 3.3 Impacts of inter-annual climate variation on parameter sensitivity

414 To explore whether inter-annual climate variation affects the sensitivity orders of
 415 parameters, each year's sensitivity order of parameters from 1980 to 2010 was
 416 obtained, and the standard deviations (SD) of orders in these years for influential
 417 parameters for WAGT and WSO are shown in Fig. 6. A large SD indicates that

418 inter-annual climate variation had large impacts on the sensitivity orders of
 419 parameters. The average SDs of parameter sensitivity orders across all the climate
 420 conditions and parameters were larger for WSO (1.15 for the $\pm 30\%$ perturbation and
 421 0.97 for $\pm 50\%$ perturbation) than for WAGT (0.63 for the $\pm 30\%$ perturbation and
 422 0.53 for $\pm 50\%$ perturbation). For each parameter, the SD in each climate condition
 423 was calculated first, and then SDs in eight climate conditions were averaged. For
 424 WAGT, the average SD of orders for RGRLMX was the largest, while those for
 425 DVRJ and FLV0.5 were relatively small. For WSO, there does not exist large
 426 differences among parameters. For both WAGT and WSO, the SDs for the $\pm 50\%$
 427 perturbation were generally smaller than those for the $\pm 30\%$ perturbation, which
 428 indicates the sensitivity analysis results using the $\pm 50\%$ perturbation were more
 429 stable.

430

431 Fig.6. Average standard deviations (SD) of parameter sensitivity orders from 1980 to
 432 2010 for influential parameters (with overall ST_i larger than 0.05) for WAGT (total
 433 aboveground dry matter, a) and WSO (dry weight of storage organs, b). For each
 434 parameter, the SD in each climate condition was calculated first, and then SDs in
 435 eight climate conditions were averaged.

436

437 Fig. 7 shows the average SDs of parameter sensitivity orders for each climate
 438 condition. For each climate condition, the SD of each parameter was calculated first,
 439 and then average SDs were calculated using the influential parameters (with overall

440 ST_i larger than 0.05). It can be seen the SDs for the $\pm 50\%$ perturbation were also
 441 smaller than those for the $\pm 30\%$ perturbation in most climate conditions, especially
 442 in Yiliang and Shenyang which have low growing-season temperature (Table 2).

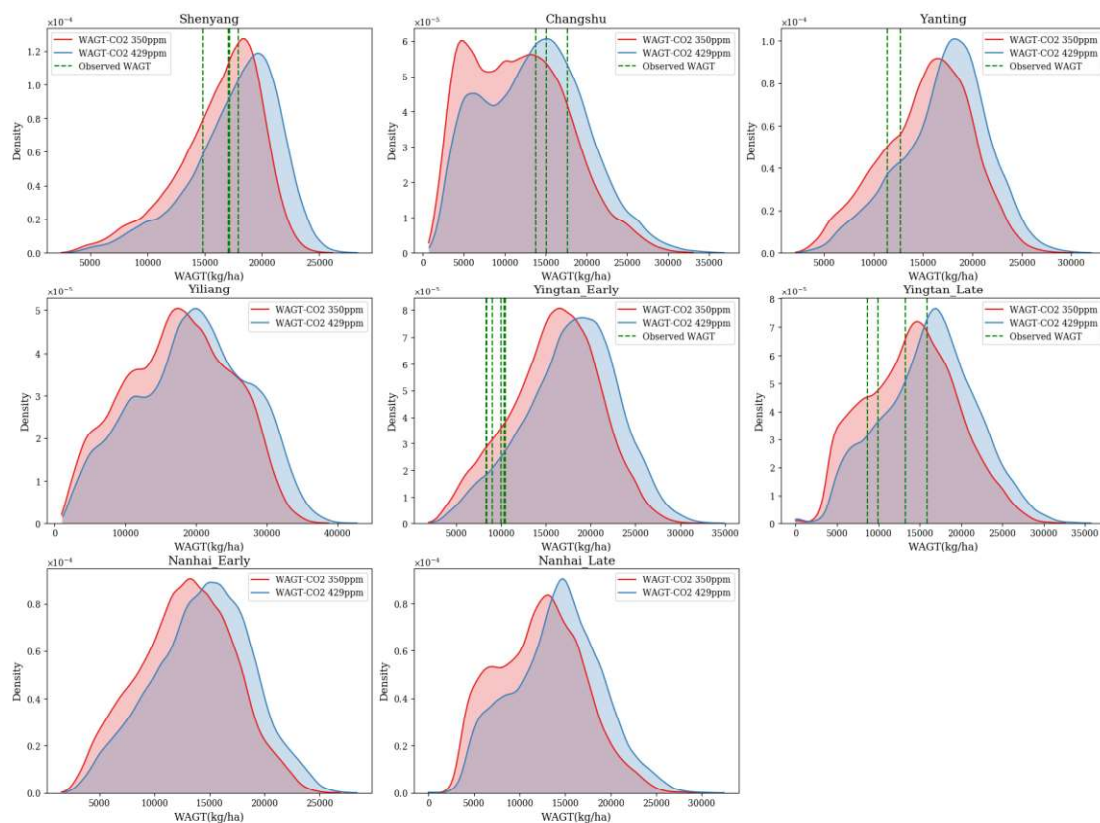

443
 444 Fig. 7 Average standard deviations (SD) of parameter sensitivity orders from 1980 to
 445 2010 for different climate conditions for WAGT (total aboveground dry matter, a) and
 446 WSO (dry weight of storage organs, b). For each climate condition, the SD of each
 447 parameter was calculated first, and then average SDs were calculated using the
 448 influential parameters (with overall ST_i larger than 0.05).

449

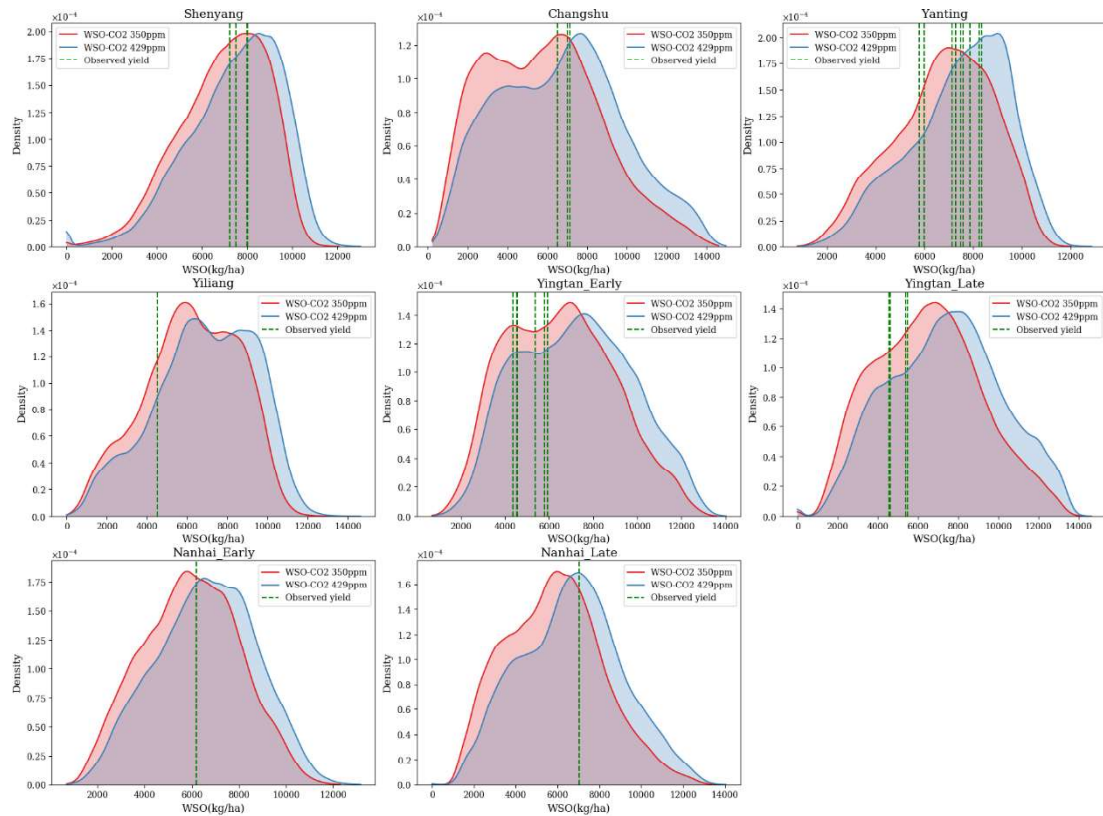

450 3.4 Distribution of the model outputs

451 Fig.8 and Fig.9 show the distribution of WAGT and WSO under the eight different
 452 climate conditions obtained by the KDE method for the $\pm 50\%$ perturbation of
 453 parameter's base value. The measured WAGT and yield were also shown in the
 454 figures as vertical dotted line. We can see that the measured values were located near
 455 to the peaks of the distribution of simulated values in all the sites. In addition, these
 456 figures clearly show that the values of WAGT and WSO under CO₂ concentration of
 457 429ppm were larger than those under CO₂ concentration of 350ppm. Taking the WSO
 458 of Shenyang as an example, there was a peak at 8000 kg/ha under CO₂ concentration
 459 of 350ppm, while this value increased to about 9000 kg/ha under CO₂ concentration
 460 of 429ppm. This can be explained by the fact that in the APSIM-Oryza model, the

461 CO₂ assimilation rate is positively correlated with ambient CO₂ concentration. It
 462 should be noted that although the peak of the distribution changed, the shape of the
 463 curve almost remained unchanged under two levels of CO₂ concentration.

464
 465 Fig.8. The distribution of WAGT (total aboveground dry matter) under eight different
 466 climate conditions obtained by the KDE (Kernel Density Estimation) method for the
 467 $\pm 50\%$ perturbation of parameter's base value. The title of each subfigure in the top of
 468 the figure represents the site and cropping system. For example, "Shenyang" means
 469 single rice in the Shenyang site, "Yingtan_Early" means early rice in the Yingtan site,
 470 etc. The red and blue colors represent the distributions of WAGT under CO₂
 471 concentration of 350 ppm and 420 ppm, respectively.

472

473 Fig.9. The distribution of WSO (dry weight of storage organs) under eight different
 474 climate conditions obtained by the KDE (Kernel Density Estimation) method for the
 475 $\pm 50\%$ perturbation of parameter's base value. The title of each subfigure in the top of
 476 the figure represents the site and cropping system. For example, "Shenyang" means
 477 single rice in the Shenyang site, "Yingtang_Early" means early rice in the Yingtang site,
 478 etc. The red and blue colors represent the distributions of WSO under CO2
 479 concentration of 350 ppm and 420 ppm, respectively.

480

481 4. Discussion

482 4.1 Differences of parameter sensitivity among different environmental 483 conditions

484 The sensitivity index of some parameters had obvious differences among the
 485 investigated eight different climate conditions. For example, the sensitivity index of
 486 RGR_LMX was much larger in Yiliang, the coldest site in this study, than in other sites
 487 for both output variables WAGT and WSO. For early rice and late rice in the same site,
 488 the sensitivity index of parameters also varied. The sensitivity of WAGT and WSO to

489 RGRLMX for early rice was consistently larger than that of late rice.
490 From the viewpoint of model structure, the different sensitivity of model outputs to
491 parameters across environmental conditions could be attributed to the interaction of
492 environmental conditions and parameters in some simulation methods. For example,
493 let us assume that a step in the simulation is to calculate a value $V=E \times P$, in which E
494 is the environmental term and P is the parameter, and then the value V is compared
495 with a threshold to determine the usage of different simulation methods in the
496 following step. If the environmental term E is large enough, it is possible that the
497 value V is always larger than the threshold for a defined range of parameters. In this
498 case, the parameter P is not sensitive. If the environmental term E is moderate,
499 whether the value V is larger than the threshold depends on the parameter P . In this
500 case, the parameter P is sensitive. If the environmental term E is small enough, it is
501 possible that the value V is always smaller than the threshold for a defined range of
502 parameters. In this case, the parameter P is not sensitive again.

503 In this study, because the simulations were conducted under irrigation and fertilization
504 conditions, water and soil conditions should not be the main influencing factor. The
505 observed differences could be mainly attributed to the temperature conditions. Taking
506 the RGRLMX parameter as an example, it was used only in calculating the relative
507 leaf area growth rate (R_l in Eq. 1 and Eq. 2, $(^{\circ}\text{C d})^{-1}$) in the exponential growth phase
508 when LAI is less than 1 (Bouman et al., 2001). R_l was then multiplied by LAI and
509 HULV (i.e. daily increase in temperature sum, $^{\circ}\text{C/d}$) to calculate the growth in LAI
510 ($gLAI$ in Eq. 2, ha leaf/ha soil/d). In cold climate, HULV will be small. If the value of
511 R_l is also very small, $gLAI$ will be very small which means slow growth rates of leaf
512 area. Thus it will take a long time for LAI to grow to 1 (e.g. the end of the exponential
513 growth phase). This will have large negative impacts on carbon assimilation and thus
514 greatly affect the value of WAGT and WSO. In contrast, HULV will have larger
515 values in the warm climate. Even RGRLMX is small, there is still larger possibility
516 for $gLAI$ to maintain a large enough value. So the dependence of WAGT on
517 RGRLMX is relatively weak in warm conditions.

518

519

520 **4.2 The little influence of CO₂ concentration setting on parameter sensitivity**

521 The CO₂ concentration is only used in the calculation of gross CO₂ assimilation rate
522 (kg CO₂ ha⁻¹ d⁻¹) in the APSIM-Oryza model. The little influence of CO₂
523 concentration setting on parameter sensitivity could be because that on the one hand,
524 some parameters are only used in the calculations that are not affected by CO₂
525 concentration. For example, the phenology calculation, where the parameters DVRJ,
526 DVRI, DVRP, and DVRR are used, and the calculation of exponential growth phase
527 of leaf development, where the parameters RGRLMX and RGRLMN are used, do not
528 depend on CO₂ concentration. Thus CO₂ concentration will not affect the sensitivity
529 of model outputs to these parameters. On the other hand, most of the other parameters
530 are used in the calculations that are linearly affected by CO₂ concentration. For
531 example, the gross CO₂ assimilation is used to calculate the daily crop growth rate
532 (kg day matter ha⁻¹ d⁻¹) through a linear relationship, and the daily crop growth rate is
533 then multiplied by the parameter FLV0.5 to get the growth rate of leaves. The relative
534 changes of values in these linear relationships will not affect the sensitivity of model
535 outputs to parameters.

536

537 **4.3 The impacts of ranges of parameter variation on sensitivity analysis results**

538 For the sensitivity analysis of crop models in existing literature, the parameter ranges
539 were usually proportionally amplified from ±5% to ±50% perturbation of the base
540 value (Marino et al., 2008; Richter et al., 2010; Tan et al., 2016; Tan et al., 2017; Yang,
541 2011; Zhao et al., 2014). Tan et al. (2017) investigated the effects of different ranges
542 of parameter variation (i.e. ±5%, ±10%, ±20%, ±30%, ±50% perturbations of
543 the base value) on the sensitivity analyses for ORYZA_V3 model, and recommended
544 the ±30% perturbation when specific ranges cannot be obtained. It should be noted
545 that this research was conducted at a single site, and the base values of some
546 parameters (e.g. the partitioning factors, leaf death rates) were determined according
547 to experimental observation (Tan et al., 2016).

548 The Yingtan site used by Tan et al., (2016, 2017) was also used in this study. Because

549 the base values of parameters in other sites of this study were not known in advance,
550 we used the base values of Tan et al. (2016) in all the sites, and used the $\pm 50\%$
551 perturbation of the base values besides the $\pm 30\%$ perturbation in order to get more
552 robust conclusions. These parameters ranges were considered to be reasonable for the
553 following reasons: 1) The parameter ranges using the 50% perturbation can cover the
554 parameter values in all the predefined cultivars of APSIM-Oryza except for the DVRP
555 parameter of cultivar BR3; 2) The measured WAGT and yield values were compared
556 with the simulated WAGT and WSO. The results showed that the measured values
557 were located near to the peaks of the distribution of simulated values in all the sites
558 (Fig.8 and Fig.9), which demonstrated the ability of the model and the parameter
559 ranges to simulate rice growth in these sites; 3) The main conclusions were consistent
560 between the results obtained from the $\pm 30\%$ perturbation and those obtained the $\pm 50\%$
561 perturbation, which demonstrates the robustness of the conclusions in this study. This
562 is consistent with Wang et al. (2013), which showed that for the WOFOST model, the
563 perturbations of parameter's base values ranging from $\pm 10\%$ to $\pm 50\%$ did not
564 change the sensitivity rankings of parameter.

565 For Yiliang and Shenyang where growing-season temperature is low, the average SDs
566 of parameter sensitivity orders from 1980 to 2010 were much larger for the $\pm 30\%$
567 perturbation than for the $\pm 50\%$ perturbation. This may be because that parameter's
568 base values of Yingtang_Late were used in all the sites of this study due to the lack of
569 experimental observation, but these base values were not suitable for the sites with
570 very different climate conditions. When the perturbation is not large enough, an
571 inappropriate base value may lead to parameter sampling ranges that cannot cover the
572 range of interest, which makes the results of sensitivity analysis not stable. When the
573 perturbation is large enough (e.g. $\pm 50\%$ in this study), the parameter sampling range
574 can cover the range of interest even an inappropriate base value is given, which makes
575 the results of sensitivity analysis stable. This highlights the need for using a larger
576 perturbation value when the base value of parameters cannot be specifically obtained.

577

578 **5. Conclusions**

579 In this study, the global sensitivity analysis of the APSIM-Oryza model was
580 performed under eight different climate conditions and two CO₂ levels for a 31-year
581 simulation period. The number (eight) of conditions considered in our study is much
582 larger than that in existing studies (most focused on only a single condition), and thus
583 our findings can provide additional insights into the APSIM-Oryza model and its
584 parameters. The sensitivity of two output variables (i.e. total aboveground dry matter
585 WAGT and dry weight of storage organs WSO) to twenty parameters was analyzed
586 using the extended FAST method. The main findings include (1) for the output
587 variables WAGT and WSO, the influential parameters (with overall ST_i larger than
588 0.05) under different climate conditions were the same, but their orders were often
589 different; (2) the sensitivity index of some parameters (e.g. RGRLMX, WGRMX and
590 SPGF) had obvious differences among different climate conditions. In particular, the
591 sensitivity index of RGRLMX is larger under cold climate than under warm climate;
592 (3) the CO₂ concentration had little influence on the results of sensitivity analysis for
593 the two output variables WAGT and WSO; (4) The range of parameter variation
594 affected the stability of sensitivity analysis results, but the main conclusions were
595 consistent between the results obtained from using the $\pm 30\%$ perturbation and those
596 obtained the $\pm 50\%$ perturbation in this study.

597 It should be noted that in existing studies and our current study, the failed simulations
598 in which crop does not reach maturity were treated as normal simulations. However,
599 these failed simulations could cause great variation of simulation results and then
600 might have large impacts on the results of sensitivity analysis. Therefore, we highlight
601 a further scientific question about how to handle these failure simulation, which needs
602 to be investigated in future studies.

740

741 Fig. A.1. The main (Si) and total (STi) sensitivity indices under eight climate
 742 conditions for the output variable WAGT (total aboveground dry matter) at maturity
 743 for the $\pm 30\%$ perturbation of parameter's base value. The title of each subfigure in
 744 the top of the figure means different environmental conditions. For example,
 745 "Shenyang" means single rice in the Shenyang site, "Yingtan_Early" means early rice
 746 in the Yingtan site, etc.

747

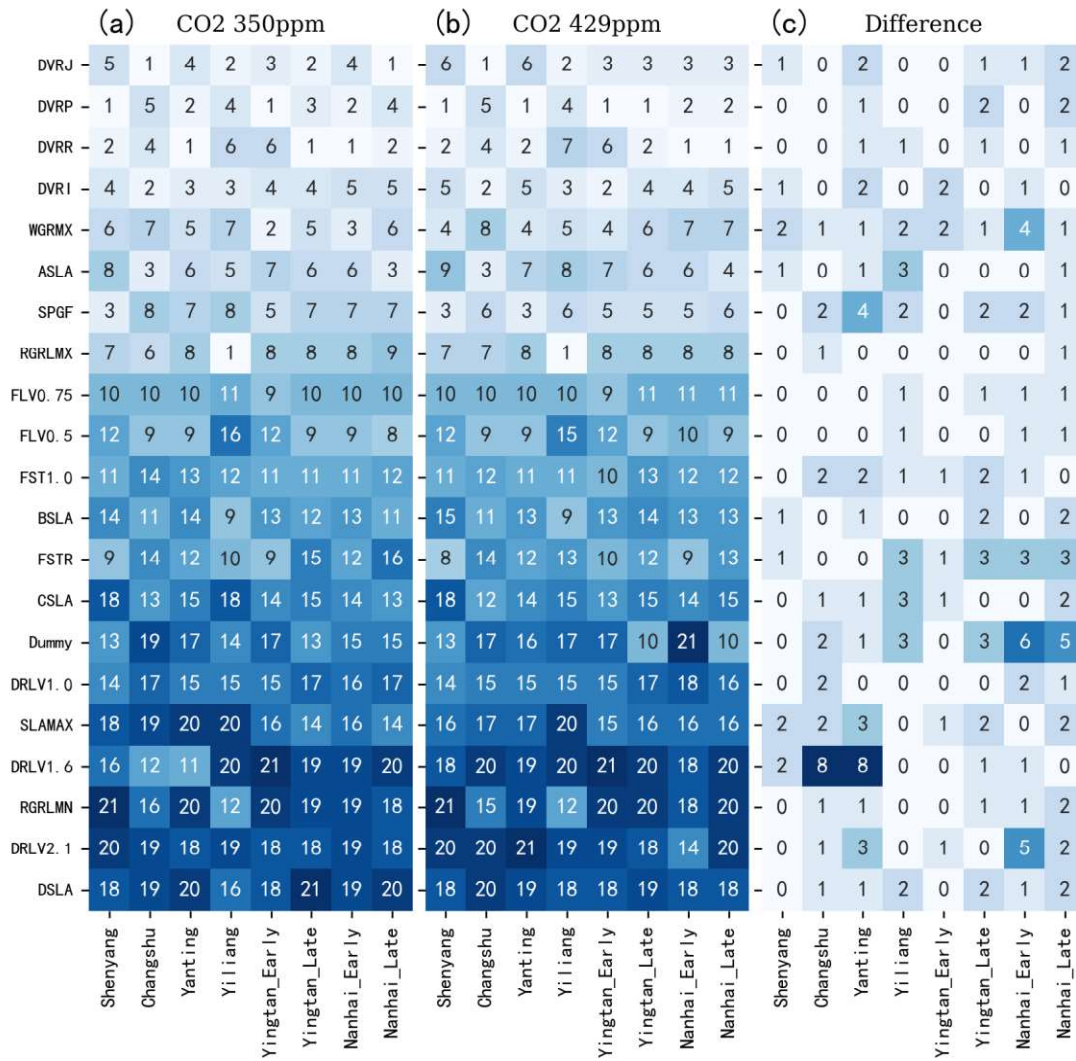

748 Fig. A.2. The main (Si) and total (STi) sensitivity indices under eight climate
 749 conditions for the output variable WSO (dry weight of storage organs) at maturity for
 750 the $\pm 30\%$ perturbation of parameter's base value. The title of each subfigure in the
 751 top of the figure means different environmental conditions. For example, "Shenyang"
 752 means single rice in the Shenyang site, "Yingtan_Early" means early rice in the
 753 Yingtan site.

754

755 Fig. A.3. Impact of CO₂ concentration on parameter sensitivity for WAGT (total
 756 aboveground dry matter) at maturity for the $\pm 30\%$ perturbation of parameter's base
 757 value. The numbers in Fig. (a) and (b) represent the order of parameters ranked by the
 758 total sensitivity index (ST_i) under two CO₂ concentrations levels (i.e. 350ppm and
 759 429ppm), and the numbers in Fig. (c) represent the changes of orders in absolute
 760 value under these two levels.

761

762

763 Fig. A.4. Impact of CO₂ concentration on the parameter sensitivity for WSO (dry
 764 weight of storage organs) at maturity for the $\pm 30\%$ perturbation of parameter's base
 765 value. The numbers in Fig. (a) and (b) represent the order of parameters ranked by the
 766 total sensitivity index (ST_i) under two CO₂ concentrations levels (350ppm and
 767 429ppm), and the numbers in Fig. (c) represent the changes of orders in absolute
 768 value under these two levels.

769

770 Table A.1. Summaries of simulation failure.

| Sites | Co2 condition | Failure times | Failure rate (%) |
|----------------|---------------|---------------|------------------|
| Shenyang | 350 ppm | 2 | 0.000633 |
| | 429 ppm | 2 | 0.000633 |
| Changshu | 350 ppm | 0 | 0 |
| | 429 ppm | 0 | 0 |

1 Table 1. Description of selected parameters and output variables in the APSIM-Oryza model

| Name | Description | Unit | Lower bound (30%) ^a | Upper bound (30%) | Lower bound (50%) | Upper bound (50%) | Base value ^b |
|-------------------|--|-----------------------|-----------------------------------|----------------------|----------------------|----------------------|-------------------------|
| Parameters | | | | | | | |
| DVRJ | Development rate in juvenile phase | (°Cday) ⁻¹ | 0.0007 | 0.0013 | 0.0005 | 0.0015 | 0.001 |
| DVRI | Development rate in photoperiod-sensitive phase | (°Cday) ⁻¹ | 0.000525 | 0.000975 | 0.000375 | 0.001125 | 0.00075 |
| DVRP | Development rate in panicle development | (°Cday) ⁻¹ | 0.000595 | 0.001105 | 0.000425 | 0.001275 | 0.00085 |
| DVRR | Development rate in reproductive phase | (°Cday) ⁻¹ | 0.0014 | 0.0026 | 0.001 | 0.003 | 0.002 |
| RGRLMX | Maximum relative growth rate of leaf area | (°Cday) ⁻¹ | 0.00595 | 0.01105 | 0.00425 | 0.01275 | 0.0085 |
| RGRLMN | Minimum relative growth rate of leaf area | (°Cday) ⁻¹ | 0.0028 | 0.0052 | 0.002 | 0.006 | 0.004 |
| ASLA | Parameter A of the function to calculate specific leaf area (SLA, ha/kg) | - | 0.00168 | 0.00312 | 0.0012 | 0.0036 | 0.0024 |
| BSLA | Parameter B of SLA | - | 0.00175 | 0.00325 | 0.00125 | 0.00375 | 0.0025 |
| CSLA | Parameter C of SLA | - | -3.15 | -5.85 | -2.25 | -6.75 | -4.5 |
| DSLA | Parameter D of SLA | - | 0.098 | 0.182 | 0.07 | 0.21 | 0.14 |
| SLAMAX | Maximum value of SLA | ha/kg | 0.00315 | 0.00585 | 0.00225 | 0.00675 | 0.0045 |
| FLV0.5 | Fraction of shoot dry matter partitioned to the leaves at DVS= 0.5 | - | 0.42 | 0.78 | 0.3 | 0.9 | 0.6 |
| FLV0.75 | Fraction of shoot dry matter partitioned to the leaves at DVS = 0.75 | - | 0.21 | 0.39 | 0.15 | 0.45 | 0.3 |
| FST1.0 | Fraction shoot dry matter partitioned to the stems at DVS =1.0 | - | 0.28 | 0.52 | 0.2 | 0.6 | 0.4 |
| DRLV1.0 | Leaf death coefficient as a function of development stage at DVS = 1.0 | - | 0.014 | 0.026 | 0.01 | 0.03 | 0.02 |
| DRLV1.6 | Leaf death coefficient as a function of development stage at DVS = 1.6 | - | 0.021 | 0.039 | 0.015 | 0.045 | 0.03 |
| DRLV2.1 | Leaf death coefficient as a function of development stage at DVS = 2.1 | - | 0.035 | 0.065 | 0.025 | 0.075 | 0.05 |
| FSTR | Fraction of carbohydrates allocated to stems stored as reserve | - | 0.175 | 0.325 | 0.125 | 0.375 | 0.25 |
| SPGF | Spikelet growth factor | no./kg | 45430 | 84370 | 32450 | 97350 | 64900 |
| WGRMX | Maximum individual grain weight | kg/grain | 1.75E-05 | 0.0000325 | 0.0000125 | 0.0000375 | 0.000025 |
| Outputs | | | | | | | |
| WAGT | Total aboveground dry matter | kg/ha | | | | | |
| WSO | Dry weight of storage organs | kg/ha | | | | | |

2 ^a Lower bound means the base value minus 30% or 50%, upper bound means the base value plus %30 or 50%. ^b Base values are obtained from Tan et al.
3 (2016).

Table 2. Location, growing-season climate and topsoil texture in the six selected sites.

| | Shenyang | Changshu | Yanting | Yiliang | Yingtian | Nanghai |
|--|-------------|-------------|-------------|-------------|--|-------------------------------|
| Rice type | Single rice | Single rice | Single rice | Single rice | Double rice | Double rice |
| Latitude | 41.52 | 31.55 | 31.27 | 24.53 | 28.25 | 23.13 |
| Longitude | 123.36 | 120.63 | 105.46 | 103.73 | 116.93 | 113.03 |
| Elevation(m) | 38 | 5 | 489 | 1699 | 41 | 1 |
| Mean daily temperature (°C) ^b | 20.30 | 25.95 | 25.04 | 20.09 | Early: 24.81 Late: 28.12 ^a | Early: 25.45 Late: 28.24 |
| Mean daily solar radiation(MJ/m ²) | 18.18 | 17.74 | 16.73 | 15.50 | Early: 16.74 Late: 17.17 | Early: 11.68 Late: 13.29 |
| Mean rainfall (mm) | 580.72 | 544.34 | 643.6 | 716.68 | Early: 1068.55 Late: 372.75 | Early: 855.73 Late: 452.53 |
| Sand (0.05-2.0mm) (%) ^c | 18.42 | 3.77 | 30.70 | 15.20 | 51.25 | 31.05 |
| Silt (0.002-0.05mm) (%) | 66.70 | 62.23 | 39.72 | 32.00 | 37.62 | 54.95 |
| Clay (<0.002mm) (%) | 14.88 | 34.00 | 20.14 | 52.80 | 11.13 | 14.00 |

^a“Early” represents early rice, “Late” represents late rice. For example, “Late: 28.96” stands for the mean temperature of late rice in Yingtian is 28.12°C, etc.

^b Mean daily temperature, mean daily solar radiation and mean rainfall are the mean value in rice growth period (from observed mean sowing date to harvesting date).

^c Soil particle size in the top layer.

Table A.1. Summaries of simulation failure.

| Sites | Co2 condition | Failure times | Failure rate (%) |
|---------------|---------------|---------------|------------------|
| Shenyang | 350 ppm | 2 | 0.000633 |
| | 429 ppm | 2 | 0.000633 |

| Nanhai_Early | 350 ppm | 0 | 0 |
| | 429 ppm | 0 | 0 |
| Nanhai_Late | 350 ppm | 61 | 0.019320 |
| | 429 ppm | 87 | 0.027555 |

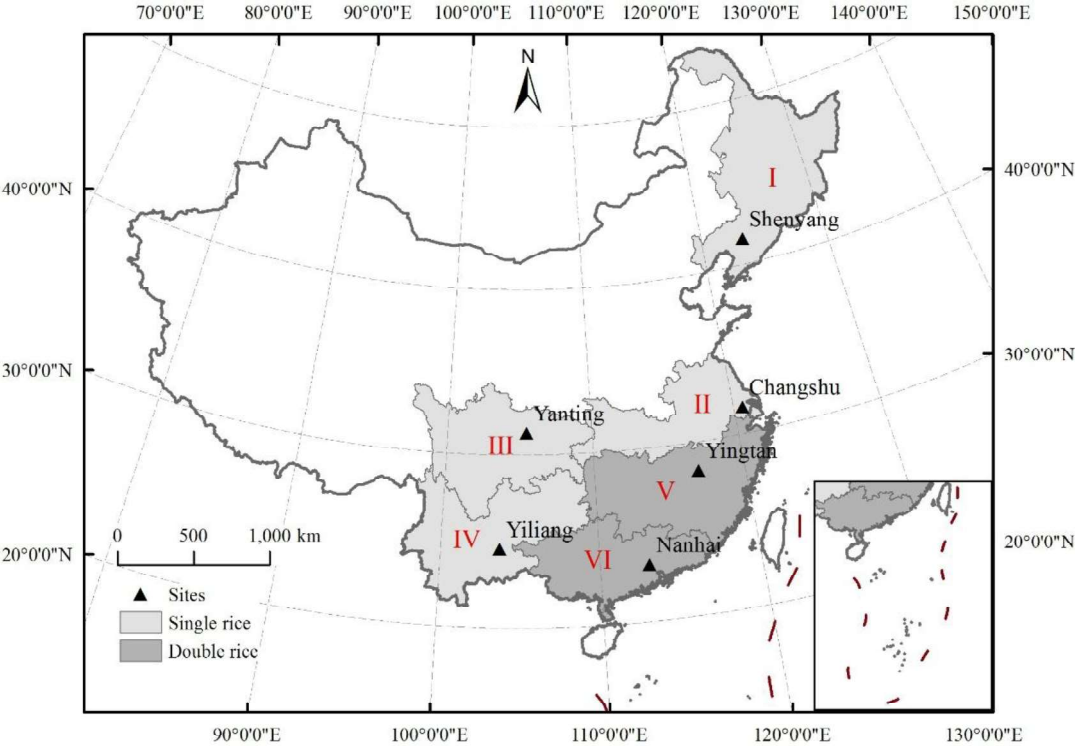

Fig.1. The spatial distribution of six rice cultivation regions across mainland China and selected sites. The six rice cultivation regions are as following: I, single rice in Northeast China, II, single rice in mid-lower Yangtze River Valley, III, single rice in Sichuan Basin, IV, single rice in Yunnan-Guizhou Plateau, V, double rice in mid-lower Yangtze River Valley and VI, double rice in South China.

Fig.2. The main (Si) and total (STi) sensitivity indices under eight climate conditions for the output variable WAGT (total aboveground dry matter) at maturity for the $\pm 50\%$ perturbation of parameter's base value. The title of each subfigure in the top of the figure means different environmental conditions. For example, "Shenyang" means single rice in the Shenyang site, "Yingtan_Early" means early rice in the Yingtan site.

Fig.3. The main (Si) and total (STi) sensitivity indices under eight climate conditions for the output variable WSO (dry weight of storage organs) at maturity for the $\pm 50\%$ perturbation of parameter's base value. The title of each subfigure in the top of the figure means different environmental conditions. For example, "Shenyang" means single rice in the Shenyang site, "Yingtan_Early" means early rice in the Yingtan site.

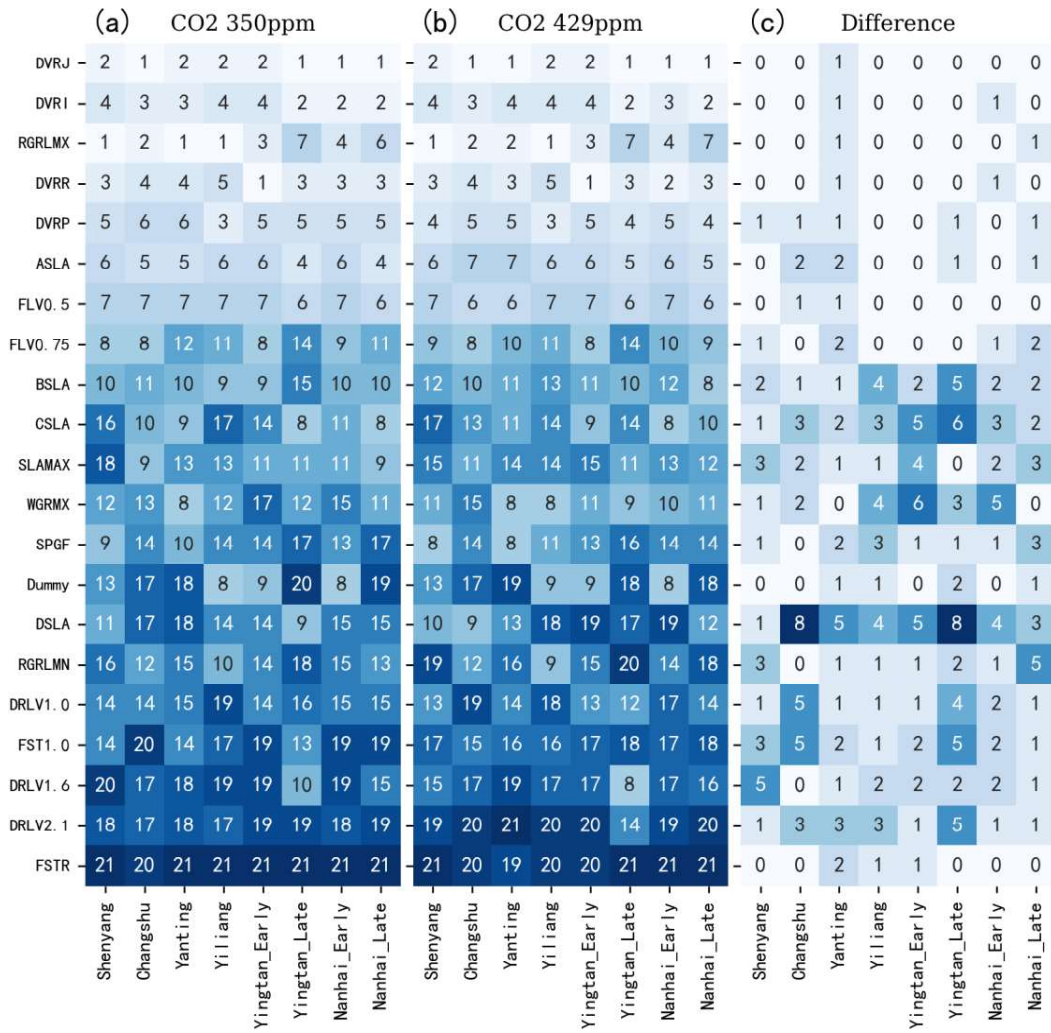

Fig.4. Impact of CO2 concentration on parameter sensitivity for WAGT (total aboveground dry matter) at maturity for the $\pm 50\%$ perturbation of parameter's base value. The numbers in Fig. (a) and (b) represent the order of parameters ranked by the total sensitivity index (STi) under two CO2 concentrations levels (i.e. 350ppm and 429ppm), and the numbers in Fig. (c) represent the changes of orders in absolute value under these two levels.

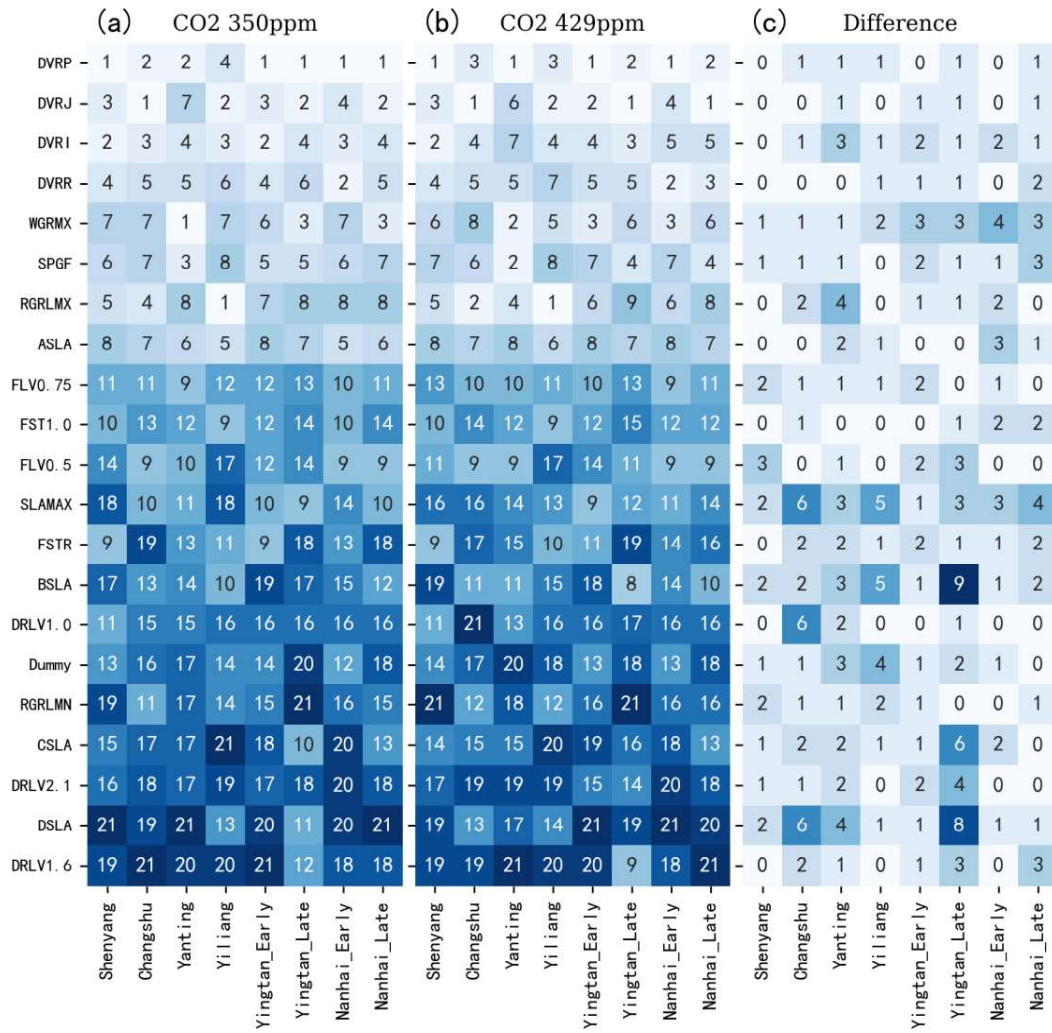

Fig.5. Impact of CO₂ concentration on the parameter sensitivity for WSO (dry weight of storage organs) at maturity for the $\pm 50\%$ perturbation of parameter's base value. The numbers in Fig. (a) and (b) represent the order of parameters ranked by the total sensitivity index (STi) under two CO₂ concentrations levels (350ppm and 429ppm), and the numbers in Fig. (c) represent the changes of orders in absolute value under these two levels.

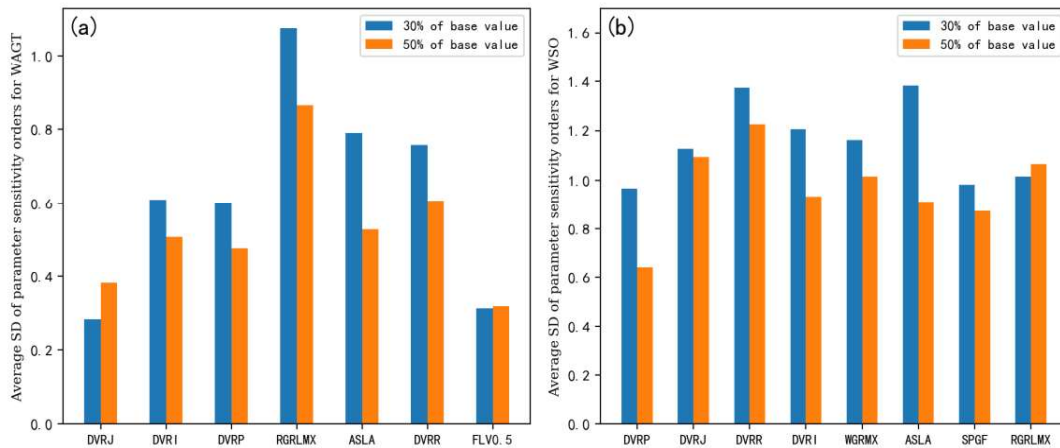

Fig.6. Average standard deviations (SD) of parameter sensitivity orders from 1980 to 2010 for influential parameters (with overall ST_i larger than 0.05) for WAGT (total aboveground dry matter, a) and WSO (dry weight of storage organs, b). For each parameter, the SD in each climate condition was calculated first, and then SDs in eight climate conditions were averaged.

Fig. 7 Average standard deviations (SD) of parameter sensitivity orders from 1980 to 2010 for different climate conditions for WAGT (total aboveground dry matter, a) and WSO (dry weight of storage organs, b). For each climate condition, the SD of each parameter was calculated first, and then average SDs were calculated using the influential parameters (with overall ST_i larger than 0.05).

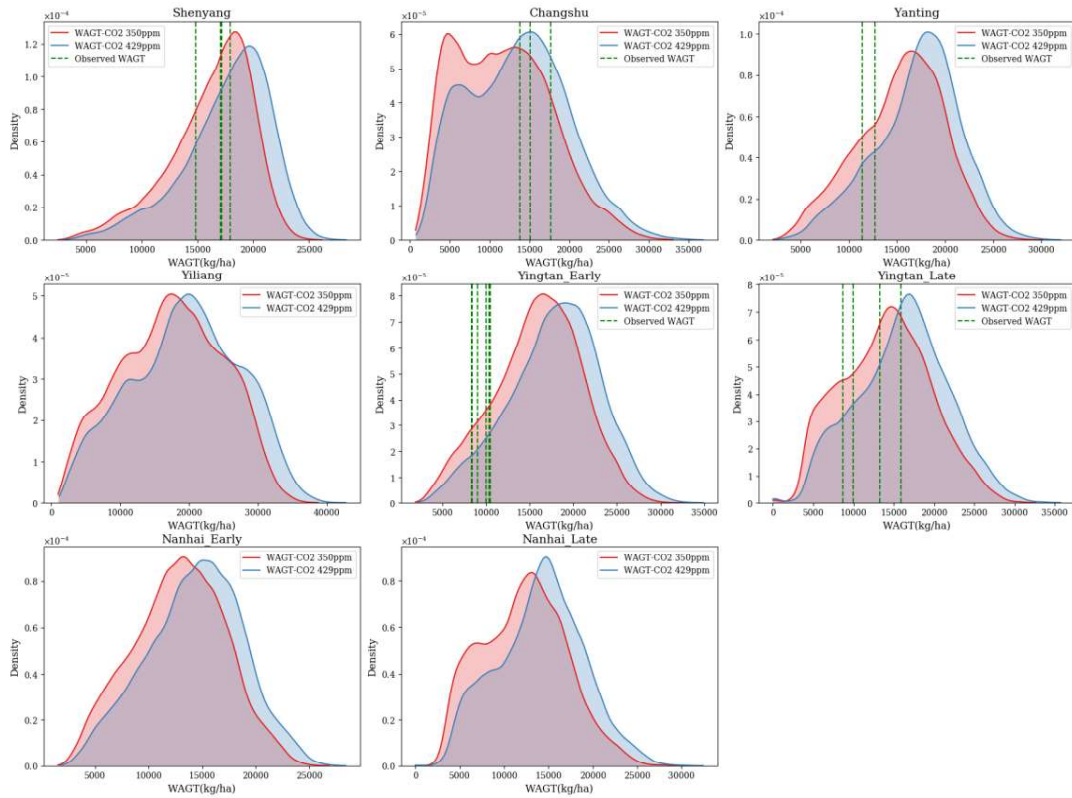

Fig.8. The distribution of WAGT (total aboveground dry matter) under eight different climate conditions obtained by the KDE (Kernel Density Estimation) method for the $\pm 50\%$ perturbation of parameter's base value. The title of each subfigure in the top of the figure represents the site and cropping system. For example, “Shenyang” means single rice in the Shenyang site, “Yingtan_Early” means early rice in the Yingtan site, etc. The red and blue colors represent the distributions of WAGT under CO₂ concentration of 350 ppm and 429 ppm, respectively.

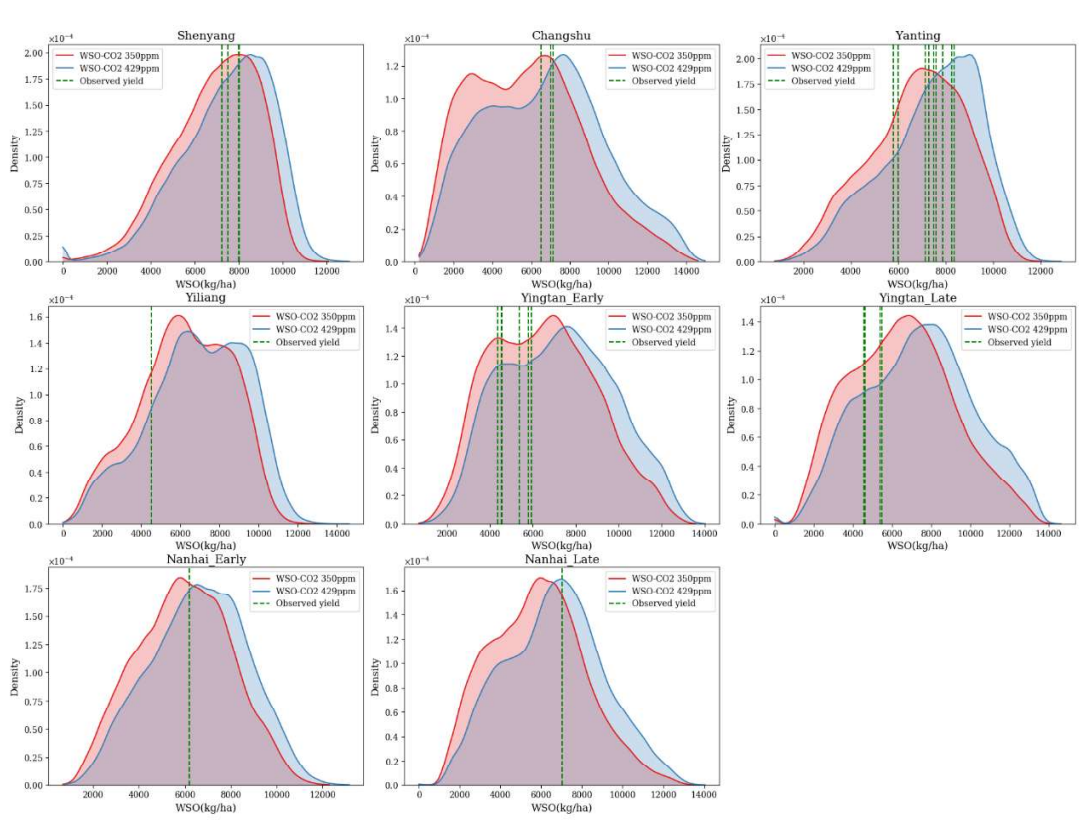

Fig.9. The distribution of WSO (dry weight of storage organs) under eight different climate conditions obtained by the KDE (Kernel Density Estimation) method for the $\pm 50\%$ perturbation of parameter's base value. The title of each subfigure in the top of the figure represents the site and cropping system. For example, “Shenyang” means single rice in the Shenyang site, “Yingtian_Early” means early rice in the Yingtian site, etc. The red and blue colors represent the distributions of WSO under CO2 concentration of 350 ppm and 420 ppm, respectively.

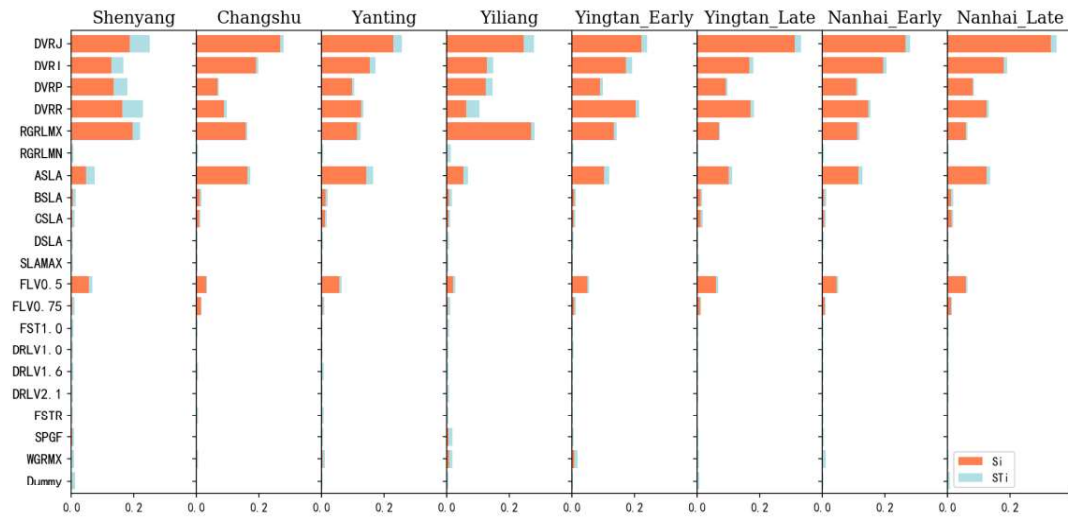

Fig. A.1. The main (Si) and total (STi) sensitivity indices under eight climate conditions for the output variable WAGT (total aboveground dry matter) at maturity for the $\pm 30\%$ perturbation of parameter's base value. The title of each subfigure in the top of the figure means different environmental conditions. For example, "Shenyang" means single rice in the Shenyang site, "Yingtan_Early" means early rice in the Yingtan site, etc.

Fig. A.2. The main (Si) and total (STi) sensitivity indices under eight climate conditions for the output variable WSO (dry weight of storage organs) at maturity for the $\pm 30\%$ perturbation of parameter's base value. The title of each subfigure in the top of the figure means different environmental conditions. For example, "Shenyang" means single rice in the Shenyang site, "Yingtan_Early" means early rice in the Yingtan site.

Fig. A.3. Impact of CO2 concentration on parameter sensitivity for WAGT (total aboveground dry matter) at maturity for the $\pm 30\%$ perturbation of parameter's base value. The numbers in Fig. (a) and (b) represent the order of parameters ranked by the total sensitivity index (STi) under two CO2 concentrations levels (i.e. 350ppm and 429ppm), and the numbers in Fig. (c) represent the changes of orders in absolute value under these two levels.

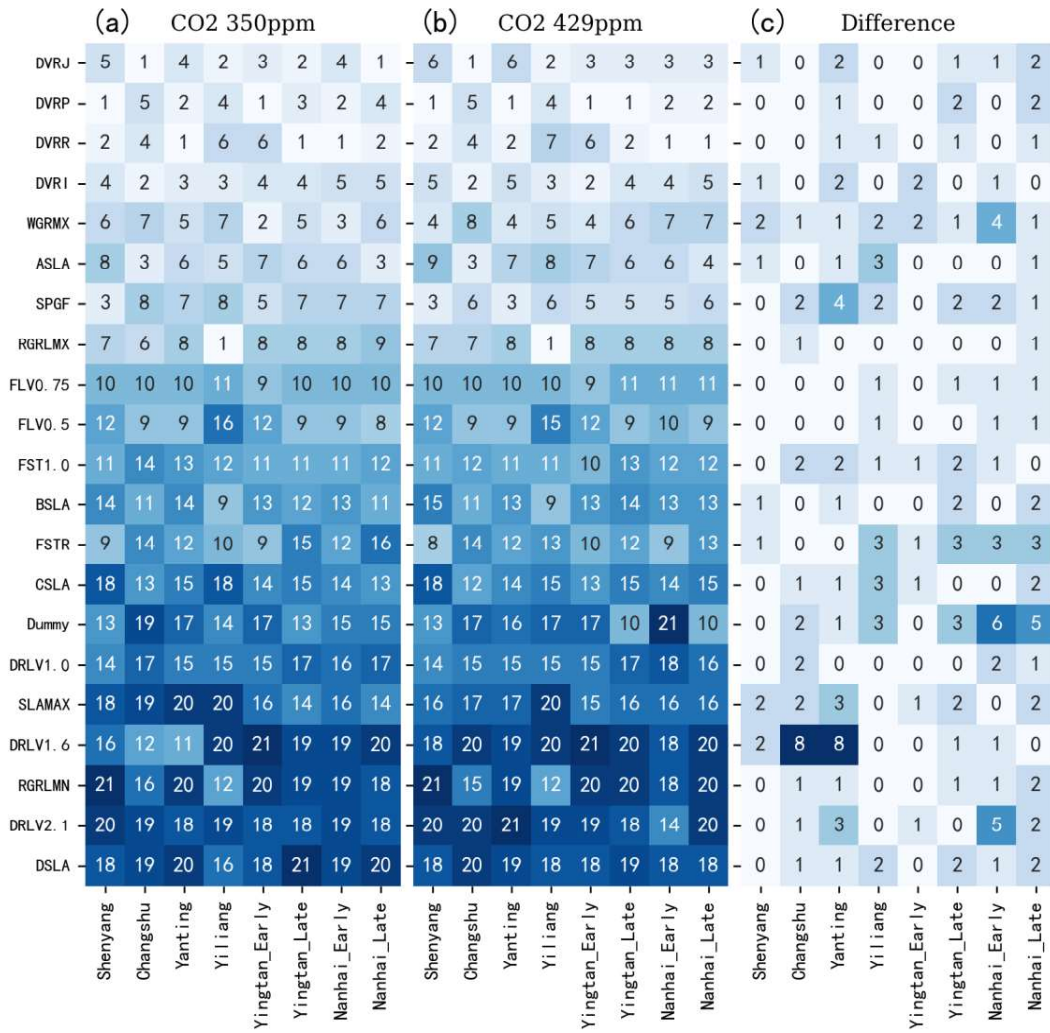

Fig. A.4. Impact of CO₂ concentration on the parameter sensitivity for WSO (dry weight of storage organs) at maturity for the $\pm 30\%$ perturbation of parameter's base value. The numbers in Fig. (a) and (b) represent the order of parameters ranked by the total sensitivity index (STi) under two CO₂ concentrations levels (350ppm and 429ppm), and the numbers in Fig. (c) represent the changes of orders in absolute value under these two levels.
