# Gait Speed Characteristics and Its Spatio-Temporal Determinants in Nursing Home Residents: A Cross-Sectional Study

## ABSTRACT

**Background and purpose:** Low and slowing gait speeds among nursing home residents are linked to a higher risk of disability, cognitive impairment, falls, and mortality. A better understanding of the spatio-temporal parameters of gait that influence declining mobility could lead to effective rehabilitation and preventative intervention. This study aims were to objectively quantify the spatio-temporal characteristics of gait in the nursing home setting and define the relationship between these parameters and gait speed.

**Methods:** One hundred nursing home residents were enrolled into the study and completed three habitual gait speed trials over a distance of 3.66 m. Trials were performed using an instrumented gait analysis. The manner in which the spatiotemporal parameters predicted gait speed was examined by univariate and multivariable regression modelling.

**Results:** The nursing home residents had a habitual gait speed of  $0.63 \pm 0.19$  m/s, a stride length of  $0.83 \pm 0.15$  m, a support base of  $0.15 \pm 0.06$  m and step time of  $0.66 \pm 0.12$  s. Multivariable linear regression revealed stride length, support base and step time predicted gait speed ( $R^2= 0.89, p<0.05$ ). Step time had the greatest influence on gait speed with each 0.1 s decrease in step time

1 22 resulting in a 0.09 m/s (95% CI 0.08 - 0.10) increase in habitual gait speed.  
2  
3

4 23 **Conclusion:** This study revealed step time, stride length and support base are  
5  
6 24 the strongest predictors of gait speed among nursing home residents. Given the  
7  
8 25 impact of low and slowing gait speed in this population, future research should  
9  
10 26 concentrate on developing and evaluating intervention programs that were  
11  
12 27 specifically designed to focus on improving step time, stride length and support  
13  
14 28 base in nursing home residents. As gait speed has been shown to be predictive  
15  
16 29 of many adverse events in older adults, we would also suggest that routine  
17  
18 30 assessments of gait speed, and if possible their spatiotemporal characteristics  
19  
20 31 be done on all nursing home residents in an attempt to identify residents with  
21  
22 32 low or slowing gait speed.

1 36 **INTRODUCTION**

2  
3  
4 37 Walking is a key physical performance task for people of all ages, including  
5  
6 38 older adults. The majority of older adults, especially those living in nursing home  
7  
8 39 (residential aged care) settings have decreased physical activity<sup>1</sup> and poor  
9  
10  
11 40 physical function as indicated by their reduced gait speed, muscle strength and  
12  
13 41 balance.<sup>2</sup> Older adults with slower gait speeds are at higher risk of disability,  
14  
15  
16 42 cognitive impairment, institutionalization, falls, and mortality.<sup>3</sup> While a variety of  
17  
18 43 gait speed thresholds exist, healthy community dwelling older adults tend to  
19  
20  
21 44 experience poorer health when their habitual gait speed is < 0.8 m/s,<sup>3,4</sup> whereas  
22  
23 45 for nursing home residents > 80 years of age, a threshold of < 0.5 m/s has been  
24  
25  
26 46 proposed.<sup>4,5</sup> A recent systematic review which included 34 studies quantifying  
27  
28 47 the gait speed of residents living in nursing homes reported a mean habitual  
29  
30  
31 48 pace gait speed of 0.48 m/s (95% confidence interval (CI) 0.40-0.55).<sup>6</sup> Gait  
32  
33 49 speeds this low suggest that most nursing home residents are limited in mobility  
34  
35  
36 50 and independence, have decreased stability and are at increased risk for many  
37  
38 51 other age-related conditions.<sup>6</sup>

39  
40 52 Currently, little is known in relation to the physical determinants or risk  
41  
42  
43 53 factors for low gait speed in low-functioning older adults and those living in  
44  
45 54 nursing home facilities. While McGough et al.<sup>7</sup> and Keogh et al.<sup>8</sup> have reported  
46  
47  
48 55 that measures of physical function, balance, lifetime physical activity levels and  
49  
50  
51 56 sitting time correlate with gait speed in these less functioning older cohorts, no  
52  
53 57 studies have quantified the spatio-temporal determinants (e.g. step length, step  
54  
55 58 rate) that determine gait speed in a nursing home population.<sup>9</sup> Figure 1  
56  
57 59 presents a pictorial representation of the relationship between selected spatio-

1 60 temporal parameters and gait speed. When compared to younger adults, older  
2  
3 61 adults walk more slowly; have a shorter step length and a broader support base  
4  
5 62 than their younger counterparts, with these differences more pronounced in  
6  
7  
8 63 older adults living in nursing home and/or with a high risk of falls.<sup>10-13</sup>  
9

10  
11 64 Insert Figure 1 here.

12  
13 65 A greater understanding of nursing home residents' gait speed and  
14  
15 66 spatio-temporal determinants may assist health professionals to identify nursing  
16  
17 67 home residents at high risk of adverse events and allow for a more specific-  
18  
19 68 tailored physical therapy and rehabilitation program for each individual.<sup>11</sup> We  
20  
21 69 would argue this is very important as indicated by a systematic review that  
22  
23 70 found exercise-related improvements in older adults' gait speed are typically  
24  
25 71 smaller in magnitude and more variable than the improvements in muscular  
26  
27 72 strength.<sup>14</sup> Specifically, semi-regular monitoring of gait speed and  
28  
29 73 spatiotemporal parameters could assist appropriate health professionals to  
30  
31 74 prescribe resistance, balance and gait exercises that target their clients' major  
32  
33 75 spatiotemporal limitations. The collection of this gait spatiotemporal data may  
34  
35 76 also allow the exercise therapist to provide their client task-relevant augmented  
36  
37 77 feedback (e.g. visual cues, instant or delayed feedback) during these exercises  
38  
39 78 to improve the transfer of training to their habitual walking performance<sup>15,16</sup>.  
40

42  
43  
44  
45  
46

47 79 This study aims were to objectively quantify the spatio-temporal  
48  
49 80 determinants and gait speed of nursing home residents and to gain some  
50  
51 81 insight into whether these spatiotemporal parameters may predict their gait  
52  
53 82 speed.

1 83 **METHODS**

2  
3 84 **Recruitment and Study Design**

4 85 The study employed a cross-sectional design, with data collected over an eight-  
5  
6  
7 86 month period across three nursing home facilities in South East Queensland,  
8  
9  
10 87 Australia. The facilities were from different providers that were either part of a  
11  
12 88 small chain of nursing homes or a not for profit organisation. The flow of  
13  
14 89 recruitment to assessment is represented in Figure 2. Facilities were  
15  
16  
17 90 approached via email and telephone follow-up seeking an expression of interest  
18  
19 91 for participation. Following an expression of interest, nursing homes were  
20  
21  
22 92 visited and the study explained to the Service Manager. Once the service  
23  
24 93 manager approved the participation of their nursing home in the project, eligible  
25  
26 94 participants were identified at a meeting between the project lead researcher  
27  
28  
29 95 and the Service Manager, head Registered Nurse and head Diversional  
30  
31  
32 96 Therapist. Ethical approval for this study was attained from the University  
33  
34 97 Human Ethics Research Committee (RO 1823) and gatekeeper's approval  
35  
36 98 obtained through the nursing homes.

37  
38  
39 99 Insert Figure 2 here.

40  
41 100 Based on study's eligibility, participants were eligible for inclusion if they were:

42  
43 101 a) aged 65 years and over, b) residing in a nursing home facility, c) ambulate  
44  
45  
46 102 independently or without a walking aid and d) could provide informed consent.

47  
48 103 The exclusion criteria included: a) end-stage terminal and/or life expectancy <6-  
49  
50  
51 104 months (ethical reasons), b) two person transfer or increased falls risk during  
52  
53 105 ambulation (as assessed by the nursing home staff), c) unable to communicate  
54  
55  
56 106 or follow instructions (personal needs beyond the scope of this project) and d)  
57  
58 107 behaviors that would endanger the participant or research staff.  
59  
60  
61  
62  
63  
64  
65

1 108 All participants were approached personally about participation and  
2  
3 109 given the opportunity to ask questions or raise concerns about the study.  
4  
5 110 Following this discussion and reading of the participant information sheet,  
6  
7  
8 111 participants provided their informed consent if they wished to participate. A total  
9  
10  
11 112 of 100 participants took part in the study, with the primary investigator  
12  
13 113 responsible for observing and administering all of the assessments.  
14

15  
16 114  
17 115 **Primary Outcome Measures: Gait Speed**  
18 116 Gait speed was assessed using a computer interfaced electronic system (model  
19  
20 117 GaitMat II, EQInc, USA) which required participants to walk across a level  
21  
22 118 pressure mat system that was 3.66 m (11.91 ft.) long.<sup>17</sup> The concurrent validity  
23  
24 119 of the spatio-temporal determinants of gait recorded with the GaitMat II is  
25  
26 120 extremely high when compared to the criterion method of 3-D motion capture ( $R$   
27  
28 121  $=.99$ ).<sup>18,19</sup> The Gait Mat II was chosen due to it being much more feasible to use  
29  
30 122 in nursing homes and 3-D motion capture. The GaitMat II system automatically  
31  
32 123 measured gait speed and spatio-temporal determinants, with this data  
33  
34 124 automatically stored in a Microsoft Excel spreadsheet.  
35  
36  
37

38  
39 125 Participants completed the trials at their habitual gait speed in their  
40  
41 126 regular footwear. The following instructions were provided, "Walk towards the  
42  
43 127 end of the room in the centre of the mat at a pace that is comfortable for you".  
44  
45 128 All measures were initiated from a standing start 2 m (6.56 ft.) from the GaitMat  
46  
47 129 II platform in order to reduce the effect that acceleration or deceleration may  
48  
49 130 have on the outcomes.<sup>20,21</sup> The average gait speed (m/s) from three attempts  
50  
51 131 was used for data analysis. Participants were allowed as much rest as required  
52  
53 132 between attempts, with rest periods typically being up to one minute.  
54  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 133 **Secondary Outcome Measures**  
2 134 A full spectrum of spatio-temporal gait determinants outputted was recorded.  
3  
4 135 These spatio-temporal gait determinants included step length, stride length,  
5  
6  
7 136 support base, step time, swing time, stance time, single support time and  
8  
9 137 double support time and are defined by the GaitMat II manual found in Table 1.  
10  
11 138 Insert Table 1 here.

12  
13  
14 139 In addition handgrip strength, the Mini-Cog test<sup>22</sup> and a simple five-item  
15  
16 140 questionnaire (SARC-F) <sup>23,24</sup> were collected for the purpose of cohort  
17  
18 141 characteristics description. Nursing home facility records provided other  
19  
20 142 relevant descriptors including the number of medical conditions and  
21  
22 143 medications.  
23  
24  
25

26 144  
27  
28

29  
30 145 **Data Management and Statistical Analysis**

31  
32 146 All data were initially checked for normality prior to analysis. As data were  
33  
34 147 normally distributed, descriptive statistics are presented as mean and standard  
35  
36 148 deviations for continuous variables. A one-way ANOVA and post-hoc Tukey and  
37  
38 149 Scheffe tests were performed to investigate between nursing home differences.  
39  
40 150 Linear regression analyses were performed to gain insight into the potential  
41  
42 151 determinants of gait speed (i.e. gait spatio-temporal determinants) in residents.  
43  
44 152 Univariate analyses of all gait spatio-temporal determinants were employed to  
45  
46 153 identify possible determinants of gait speed (two-tailed). Factors with a  
47  
48 154 significance  $p \leq 0.10$  determined from simple linear regression analyses were  
49  
50 155 included in the multiple linear regression model. This multivariable model  
51  
52 156 determined which combination of variables best-predicted gait speed in  
53  
54  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 157 residents. The 95% confidence interval (95% CI) was included for the  
2  
3 158 coefficients in the multivariable model. All data were analysed using SPSS  
4  
5 159 statistic software (version 22) with statistical significance set at  $p < 0.05$  a priori.  
6  
7  
8

## 9 160 **RESULTS**

### 11 161 **Participants**

12 162 One hundred of 166 (60.24%) invited, eligible residents were recruited to the  
13  
14 163 study. There were no significant differences between all variables for nursing  
15  
16 164 home cohorts in this study ( $p > 0.05$ ), thus data combined into one group for  
17  
18 165 analysis. Cohort data are present in Table 2. The average age of the 100  
19  
20 166 residents was 85.7 (7.1) years with a mean gait speed of 0.63 (0.19) m/s, an  
21  
22 167 average of 11.0 (4.9) medical conditions and 14.0 (5.8) prescribed medications.  
23  
24 168 There were no significant differences with gait speed and spatio-temporal  
25  
26 169 parameters, handgrips strength, sarcopenia status and medications and chronic  
27  
28 170 diseases across males and females. However, males were significantly younger  
29  
30 171 ( $p = 0.038$ ) and had a lower Mini-Cog assessment ( $p = 0.002$ ) in comparison to  
31  
32 172 females.  
33  
34  
35

36 173 Insert Table 2 here.  
37  
38  
39  
40  
41  
42

43 174 The majority of participants (79%,  $n = 79/100$ ) presented with below  
44  
45 175 normal habitual gait speeds ( $< 0.80$  m/s), whilst 26% ( $n = 26/100$ ) ambulated at  
46  
47 176 below the mean reported for nursing facilities residents ( $< 0.48$  m/s, 95% CI  
48  
49 177 0.396-0.554).<sup>6</sup>  
50  
51  
52

53 178 Results of the univariable linear regression analyses identified three  
54  
55 179 spatio-temporal factors as being predictive of gait speed: stride length  
56  
57 180 ( $p < 0.001$ ), support base ( $p < 0.001$ ) and step time ( $p = 0.002$ ) (see Table 3). Of  
58  
59  
60  
61  
62  
63  
64  
65

1 181 these factors, stride length contributed to the largest change in gait speed, with  
2  
3 182 each 0.1 m increase in stride length resulting in an average 0.09 m/s (95% CI  
4  
5  
6 183 0.06 – 0.13) faster habitual gait speed.

7  
8 184 Insert Table 3 here.

9  
10 185 The multivariable linear regression model that included stride length,  
11  
12 186 support base and step time predicted 89% ( $R^2 = 0.89$ ) of the variation in gait  
13  
14 187 speed (see Table 3). Specifically, step time contributed to the largest change in  
15  
16 188 gait speed with every 0.1 s decrease in step time resulting in a mean increase  
17  
18 189 in gait speed of 0.09 m/s (95% CI 0.08 – 0.10). A 0.1 m increase in stride length  
19  
20 190 was also associated with a mean increase of 0.08 m/s (95% CI 0.07 – 0.09) in  
21  
22 191 gait speed. The third determinant identified in the multivariable regression,  
23  
24 192 support base appeared to have a smaller effect on gait speed, with a 0.1 m  
25  
26 193 decrease in support base resulting in a mean gait speed increase of 0.04 m/s  
27  
28 194 (95% CI 0.02 – 0.07).

## 29 30 31 32 33 34 35 36 37 195 **DISCUSSION**

38  
39 196 This study demonstrated that nursing home residents who can self-ambulate  
40  
41 197 with or without a walking aid still walk at a gait speed ( $0.63 \pm 0.19$  m/s) and  
42  
43 198 possess spatiotemporal parameters that place them at high risk of falls and  
44  
45 199 other adverse age-related events.<sup>3,11,12</sup> A total of 79 participants presented with  
46  
47 200 below normal habitual gait speeds ( $< 0.80$  m/s), which is a threshold defined to  
48  
49 201 screen for sarcopenia in older adults aged 80 years and older.<sup>25</sup> A total of 27  
50  
51 202 participants also walked at a threshold below 0.48 m/s which a meta-analysis of  
52  
53 203 48 studies found to be the mean gait speed for older adults in nursing homes.<sup>6</sup>  
54  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 204 Results of the regression analyses also indicated that nursing home  
2  
3 205 residents who ambulated at a slower habitual gait speed were more likely to  
4  
5 206 have an increased step time, shorter stride length and a wider support base  
6  
7  
8 207 than their more ambulatory counterparts. While the finding that some spatio-  
9  
10 208 temporal parameters do predict gait speed is not overly surprising, to our  
11  
12 209 knowledge this is the first study to investigate the potential for spatio-temporal  
13  
14 210 determinants to determine gait speed in the nursing home setting. The  
15  
16 211 importance of the spatio-temporal parameters in determining gait speed also  
17  
18 212 appear consistent with Sterke et al.<sup>11</sup> and Taylor et al.<sup>12</sup> who demonstrated that  
19  
20 213 slower older walkers with increased falls risk had shorter stride lengths, longer  
21  
22 214 double support times and a wider support base when compared to aged  
23  
24 215 matched individuals with no falls history.

25  
26  
27  
28  
29 216 The significant ability of spatio-temporal determinants such as step time,  
30  
31 217 stride length and support base to determine gait speed in the current study ( $R^2$   
32  
33 218 = 0.89) and falls in previous studies<sup>11,12</sup> would appear to reflect a variety of  
34  
35 219 biomechanical concepts. For example, the ability of step time and stride length  
36  
37 220 to determine gait speed may be explained by the impulse-momentum  
38  
39 221 relationship and/or the nursing home residents' reduced ability to maintain  
40  
41 222 balance during the gait cycle. It is fair to conclude that reduced lower-body  
42  
43 223 muscle strength and power may mean that the nursing home residents require  
44  
45 224 greater single/double support times to produce the necessary impulse (force  
46  
47 225 multiplied by time) to propel their body forward during the gait cycle.<sup>26</sup> Their  
48  
49 226 reduced force production ability and greater stance time would then contribute  
50  
51  
52  
53  
54 227 to a reduced stride length, increased step time and ultimately a reduced  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 228 habitual gait speed. Poor stride length may also be suggestive of shuffling gait  
2  
3 229 and low plantar flexor and hip flexor strength.<sup>26</sup> Therefore, certain exercises  
4  
5 230 such as calf raises and leg raises coupled with gait training may need to be  
6  
7  
8 231 incorporated in resistance training programs to improve gait speed in nursing  
9  
10 232 home residents.<sup>21</sup>

11  
12  
13 233 The clinical significance of this study is that gait speed characteristics  
14  
15 234 and spatio-temporal determinants are becoming more easily measured and  
16  
17  
18 235 analysed in nursing home settings. Health professionals can then use this  
19  
20 236 individualized gait data to identify residents at risk of adverse events and  
21  
22 237 intervene where appropriate by providing an individualized exercise intervention  
23  
24  
25 238 for each resident. In doing so, residents are likely to benefit more from these  
26  
27 239 exercise programs as they are better tailored to the specific spatio-temporal  
28  
29 240 parameters underlying the participants' poor gait speed and/or falls risk. Such  
30  
31 241 an approach may also improve exercise adherence as these programs can  
32  
33 242 better concentrate on improving gait performance in activities of daily living  
34  
35 243 (ADL).<sup>27</sup>

36  
37  
38  
39  
40 244 Collectively, the manner in which the nursing home residents walk (as  
41  
42 245 described by their spatio-temporal determinants) have major implications to  
43  
44 246 exercise therapy and rehabilitative approaches to improving gait speed in this  
45  
46  
47 247 cohort. With the clinical implications being that if health professionals can  
48  
49 248 continually monitor and assess gait speed and spatio-temporal determinants,  
50  
51 249 we may be able to decrease or prolong the amount of residents who are  
52  
53 250 induced into the vicious cycle of reduced physical activity and decreased  
54  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 251 mobility and physical performance that have a direct effect on their health and  
2  
3 252 survival.  
4

5  
6 253 However, it is also possible that the tendency for the slower nursing  
7  
8 254 home residents to have shorter stride lengths, increased step times and wider  
9  
10 255 support bases may be indicative of a compensation for their reduced strength  
11  
12 256 and dynamic stability. Longer strides and a narrower support base increase the  
13  
14 257 distance that the centre of mass travels outside the anterior-posterior and  
15  
16 258 medial-lateral bases of support, respectively.<sup>26</sup> As Sherrington et al.<sup>28</sup> has  
17  
18 259 reported that exercise programs that do not sufficiently challenge balance may  
19  
20 260 actually increase rather than decrease the risk of falling of nursing home  
21  
22 261 residents, we would recommend that nursing home residents with short strides  
23  
24 262 and wide support bases focus initially on improving their static and dynamic  
25  
26 263 balance. Once balance has been improved in the anterior-posterior and medial  
27  
28 264 lateral directions, these residents may further prioritize resistance and gait  
29  
30 265 retraining to safely improve their gait speed and overall mobility.  
31  
32  
33  
34  
35  
36

37 266 Given the interplay between decreasing mobility and increasing disability,  
38  
39 267 the monitoring of gait speed by health professionals (and if possible the primary  
40  
41 268 spatio-temporal determinants) on at least an annual basis in the nursing home  
42  
43 269 setting has been recommended.<sup>8,29</sup> For those nursing home residents identified  
44  
45 270 with poor and slowing mobility, systematic review evidence suggests that  
46  
47 271 regular progressive resistance and balance training can improve their habitual  
48  
49 272 gait speed by 0.07 m/s (95% CI 0.02-0.11) when compared to non-exercising  
50  
51 273 controls.<sup>30</sup> While these reported improvements in gait speed are positive, there  
52  
53 274 may be two potential criticisms of the studies reviewed in this meta-analysis  
54  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 275 (and the wider literature). The first is that the studies have typically used quite  
2  
3 276 generic exercise prescriptions that focus on improving muscular hypertrophy  
4  
5  
6 277 and strength in a variety of muscle groups. Based on emerging evidence that  
7  
8 278 reduced gait speed in older adults is primarily a result of reduced ankle  
9  
10 279 plantarflexor rather than hip or knee extensor moment and muscle power,<sup>26</sup> a  
11  
12  
13 280 greater focus on increasing the muscle strength and power of the plantarflexors  
14  
15  
16 281 compared to the traditional focus on the knee and hip extensors may be  
17  
18 282 warranted. In addition, the majority of studies in this area that have included  
19  
20  
21 283 balance training primarily used static balance tasks that require the older adults  
22  
23 284 to hold a position for a period of 10-20 s e.g. two feet stands on unstable  
24  
25 285 surface or with eyes closed or semi-tandem/tandem stance. Based on our  
26  
27  
28 286 results, we suggest that dynamic balance ability, which would appear more  
29  
30  
31 287 closely related to the balance requirements of human gait, be taught by health  
32  
33 288 professionals on a weekly basis. Therefore, nursing home residents may obtain  
34  
35 289 greater gait speed benefit from performing dynamic balance tasks (e.g. stepping  
36  
37 290 and perturbation response) than static balance tasks.<sup>31-33</sup>

40 291 The Gait Mat II provided a feasible, reliable and valid tool to measure gait  
41  
42 292 speed and spatio-temporal determinants in nursing home adults.<sup>2,18,19</sup> New  
43  
44 293 equipment has been developed since the data collection of this study. One  
45  
46  
47 294 suggestion for future studies would be to use inertial sensors<sup>34</sup> which may be a  
48  
49  
50 295 more portable and affordable gait assessment. Such advancements in inertial  
51  
52 296 sensor technology would more easily allow health professionals to routinely  
53  
54 297 monitor gait speed and spatiotemporal parameters in the nursing home setting,  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 298 which may further increase allow the development of targeted exercise  
2  
3 299 programs for each nursing home resident.  
4

5  
6 300 Participation selection bias is a limitation that may have influenced our  
7  
8 301 findings as the inclusion criteria deemed that a participant should have the  
9  
10 302 ability to walk with or without an aid. A total of 55% of residents in the nursing  
11  
12 303 home facilities were ineligible because of the inability to mobilize or because  
13  
14 304 they were deemed too high a risk to participate. Because of this bias in  
15  
16 305 selecting individuals who were ambulant (with or without assistive devices), the  
17  
18 306 gait speed and spatiotemporal parameters obtained in this study may not be  
19  
20 307 generalized to all nursing home residents. Nevertheless, the participants in the  
21  
22 308 current study were still below the cut off for physical performance and at risk of  
23  
24 309 further decreased disability, cognitive decline and mortality,<sup>35</sup> with every 0.1 m/s  
25  
26 310 reduction in gait speed equating to a 10% decrease in older adult's ability to  
27  
28 311 perform ADLs.<sup>36</sup> It must also be acknowledged that static or dynamic balance  
29  
30 312 ability were not directly assessed in this study. Therefore, while our proposition  
31  
32 313 of poor dynamic balance contributing to the reduced gait speed of nursing home  
33  
34 314 participants has some experimental support,<sup>37,38</sup> we cannot explicitly state that  
35  
36 315 is the case with our participants.  
37

## 47 317 **CONCLUSIONS**

48  
49 318 This is the first study to investigate gait speed characteristics and spatio-  
50  
51 319 temporal determinants in the nursing home setting. While our cross-sectional  
52  
53 320 study suggests that step time, stride length and support base are highly  
54  
55 321 predictive of gait speed in nursing home residents, longitudinal research is  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 322 required to determine if changes in these three spatio-temporal determinants  
2  
3 323 may be predictive of changes in gait speed. If these longitudinal relationships  
4  
5 324 between gait speed and spatio-temporal determinants can be found, health  
6  
7 325 professionals may be better able to alter aspects of their exercise prescription  
8  
9 326 and augmented feedback approach to improve outcomes for nursing home  
10  
11 327 residents.

528

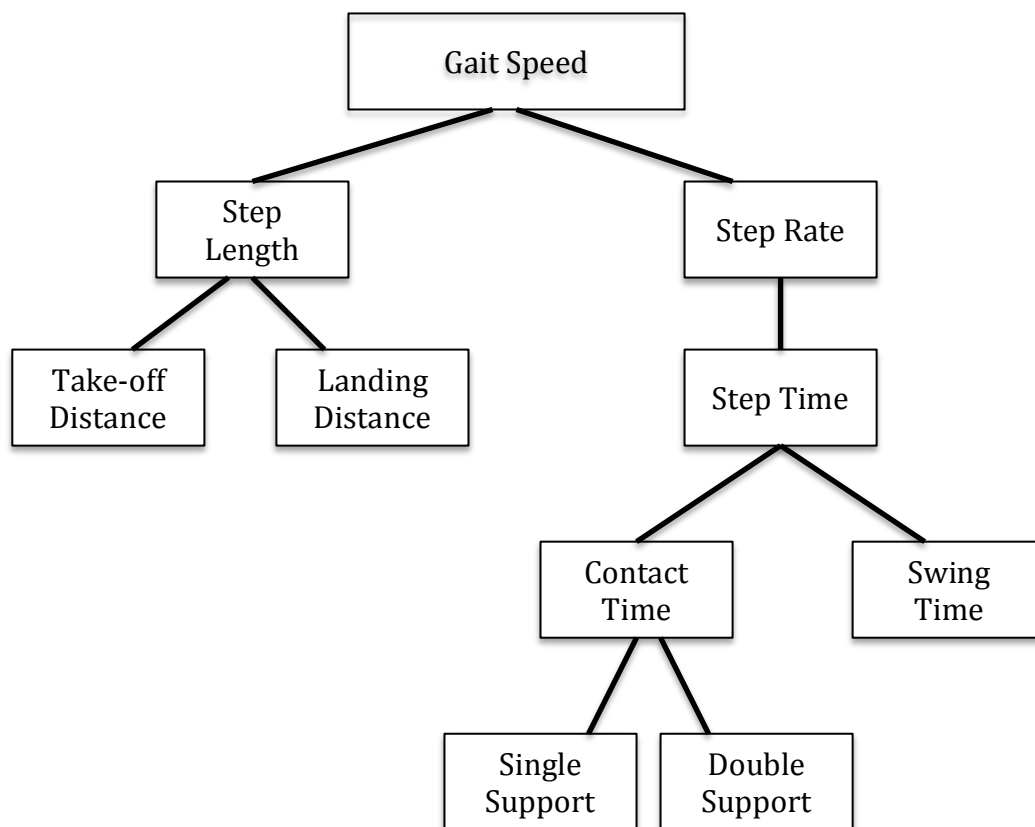

Figure 1. Deterministic Model of Gait Speed Outlining the Direct Relationships Between the Spatio-Temporal Determinants and Gait Speed.

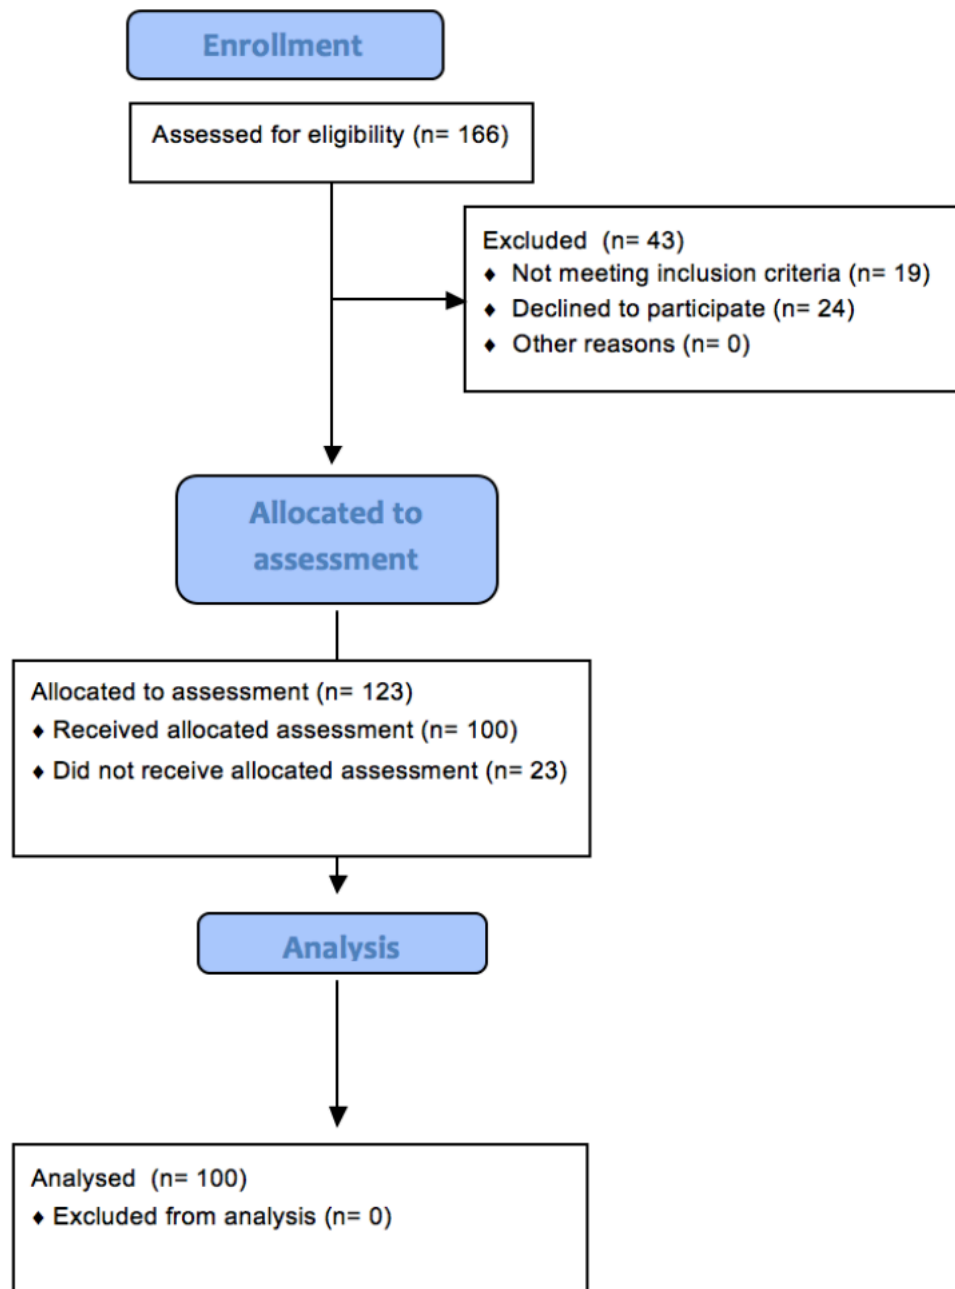

Figure 2. Consort Flow Diagram of the Recruitment Process Within the Nursing Home Settings.

Table 1: Spatio-temporal gait determinants and definitions as defined by the GaitMat II manual.

Spatio-temporal gait determinants	Definitions
Step length	The distance from the first switch closure of one footprint to that of the footprint on the contralateral side. <sup>39</sup>
Stride length	The distance from the first switch closure of one footprint to the next footprint on the ipsilateral side. <sup>39</sup>
Support base	The medial lateral distance across the mat to the innermost switch closure for one footprint from the innermost switch closure of the previous footprint on the contralateral side. <sup>39</sup>
Step time	The time to the earliest switch closure of a footfall from the earliest switch closure of the previous footfall on the contralateral side. <sup>39</sup>
Swing time	The time to the earliest switch closure of a footfall from the latest switch opening of the previous footfall on the ipsilateral side. <sup>39</sup>
Stance time	The time to the latest switch opening of a footfall from the earliest switch closure of the same footfall. <sup>39</sup>
Single support time	The time to the earliest switch closure of the next footfall on the contralateral side from the latest switch opening of the previous footfall on the contralateral side. <sup>39</sup>
Double support time	The time to the latest switch opening of the previous footfall on the contralateral side from the earliest switch closure of a footfall. <sup>39</sup>

Table 2: Characteristics of the Cohort of 100 Nursing Home Residents.

<b>Parameter</b>	<b>Group Mean (SD)</b>	<b>Females (n=67) Mean (SD)</b>	<b>Males (n=33) Mean (SD)</b>
<b>Age, y</b>	85.7 (7.1)	86.1 (6.6)*	85.0 (8.1)
<b>Handgrip Strength, kg</b>	11.1 (4.9)	10.7 (4.2)	11.7 (6.2)
<b>Mini COG, #</b>	1.2 (0.4)	1.8 (0.4)*	1.3 (0.5)
<b>SARC-F, #</b>	5.5 (3.3)	4.9 (3.3)	6.6 (3.1)
<b>Medical Conditions, #</b>	11.0 (4.9)	11.4 (4.9)	10.2 (4.9)
<b>Medications, #</b>	14.0 (5.8)	13.8 (6.1)	14.4 (5.3)
<b>Gait speed, m/s</b>	0.63 (0.19)	0.65 (0.20)	0.58 (0.16)
<b>Step length, m</b>	0.41 (0.08)	0.42 (0.07)	0.41 (0.07)
<b>Stride length, m</b>	0.83 (0.15)	0.84 (0.16)	0.81 (0.14)
<b>Support base, m</b>	0.15 (0.06)	0.16 (0.06)	0.15 (0.07)
<b>Step time, s</b>	0.66 (0.12)	0.64 (0.12)	0.70 (0.12)
<b>Swing time, s</b>	0.42 (0.07)	0.41 (0.07)	0.44 (0.08)
<b>Stance time, s</b>	0.91 (0.20)	0.88 (0.19)	0.98 (0.20)
<b>Single support Time, s</b>	0.42 (0.07)	0.41 (0.06)	0.43 (0.08)
<b>Double support Time, s</b>	0.24 (0.07)	0.23 (0.06)	0.27 (0.08)

# = number; Mini COG = Mini Cognitive test; SARC-F = Sarcopenia Five-Item  
Questionnaire

\* = Statistical significance  $p < 0.05$ .

Table 3: Univariable and Multivariable Linear Regression Model of the Spatio-Temporal Predictors for Habitual Gait Speed in 100 Residents Living in Nursing Homes.

Factor	Univariable		Multivariable	
	Coefficient (95% CI)	<i>p</i> -value	Coefficient (95% CI)	<i>p</i> -value
Stride length, m	0.93 (0.55 – 1.31)	< 0.001	0.83 (0.74 – 0.92)	< 0.001
Support base, m	-0.51 (-0.77 to -0.26)	< 0.001	-0.44 (-0.68 to -0.21)	< 0.001
Step time, s	-0.70 (-1.13 to -0.27)	0.002	-0.92 (-1.03 to -0.81)	< 0.001

CI = Confidence Interval.

R<sup>2</sup> of multiple regression equals 0.892.

Note: All results significant  $p < 0.05$ .
