Differential loading of the Argonaute complex in Epstein-Barr
Virus (EBV)-infected cell lines derived from diffuse large
B-cell lymphoma (DLBCL)

Dissertation zur Erlangung des Grades eines Doktors der
Naturwissenschaften der Medizinischen Fakultät
der **UNIVERSITÄT DES SAARLANDES**
2018

Vorgelegt von: Mohammad Hiresch Ayoubian
geb. am. 4.07.1980 in Tehran, Iran

Declaration

I hereby declare that the Ph.D. thesis entitled “Differential loading of the Argonaute complex in Epstein-Barr Virus (EBV)-infected cell lines derived from diffuse large B-cell lymphoma (DLBCL)” is a presentation of my original research work. Where other sources of information have been used, they have been acknowledged. No portion of work contained in this thesis has been submitted in support of any application for any other degree or qualification.

Homburg,

Zusammenfassung

MicroRNAs sind essentielle post-transkriptionelle Regulatoren der Genexpression die an unterschiedlichen Prozessen wie Entwicklung, Signaltransduktion oder Wachstumskontrolle durch Bindung und Inhibition der Translation ihrer mRNA Ziel mRNAs beteiligt sind. Obwohl angenommen wird, dass ihre relative Expression in der Zelle das Ausmaß ihrer biologischen Funktion bestimmt, zeigt die Beladung der „Argonaute“ (Ago)-mRNA Komplexe mit miRNAs deren Relevanz besser an.

In der vorliegenden Arbeit wurde die miRNA Beladung der Ago-Komplexe mit den miRNA Profilen der Gesamt-RNA zweier diffus-großzelliger B-Zell Lymphome (DLBCL) Linien nach Epstein-Barr Virus (EBV) -Infektion, verglichen. DLBCL ist ein hochmaligner Tumor, welcher in Aktivierte B-Zell (ABC-) und Germinal Center B-Zell (GCB-) DLBCL unterschieden wird. Etwa 10% aller DLBCLs sind mit dem onkogenen EBV, welches selbst 44 reife miRNAs exprimiert, infiziert.

Die miRNA Profile aus Gesamtzellextrakten und des Ago2-Profiles zweier DLBCL Linien wurden durch Hochdurchsatzsequenzierung (RNA-Seq) analysiert. In den Gesamt-Profilen konnten zwischen 713-851 humane miRNAs identifiziert werden, während die Ago2-Profile 1102-1372 humane miRNAs ergaben. Bei Anwendung eines 0.1% „cut-offs“ verringerte sich die Zahl der funktionellen miRNAs auf 56-62., welche jedoch immer noch 92-95% aller miRNAs-reads ausmachten. In Abhängigkeit von Latenztyp repräsentierten die viralen miRNAs 1.6% - 28% aller „reads“. In beiden Zelllinien hatte die EBV-Infektion den Verlust von miRNAs im Ago2-Komplex zur Folge. Die erhobenen Daten konnten für ausgewählte miRNAs durch RT-qPCR und im Northern Blot bestätigt werden. Auch die Analyse der Ago2-Komplexe der einzelnen Zellen ergab eine auffällige Umverteilung miRNAs zwischen Gesamt- und Ago2-assoziierten miRNAs. Zum Beispiel war die miRNA miR-423 in allen Zellen 6-8-fach im Ago2-Komplex angereichert, während die miR-142 im Ago2-Komplex depletiert vorliegt, was auf einen Funktionsverlust hinweist. Die hier erhobenen Daten werden zum weiteren Verständnis des Beitrags von miRNAs bei der Entstehung und Aufrechterhaltung von DLBCLs leisten.

Summary

MicroRNAs are important post-transcriptional regulators of gene expression in all eukaryotic cells and play essential roles, i.e. in development, signal transduction or growth control by binding to and inhibiting the translation of their mRNA targets. While it is widely assumed that their overall level in a cell reflects their functional relevance, the loading and transfer of miRNAs to the “Argonaute” (Ago)-mRNA complex appears to give a more accurate indication of their activity in a cell.

In this thesis, the miRNA loading of the Ago complex was compared with the total cellular miRNA profile of two cell lines derived from diffuse large B-cell lymphoma (DLBCL) in comparison with their Epstein-Barr Virus infected counterparts. DLBCL is a highly malignant tumor subdivided into Activated B-cell (ABC-) and Germinal Center B-cell (GCB-) subtypes. About 10% of DLBCL are infected with the oncogenic Epstein-Barr virus which itself encodes 44 mature miRNAs.

The cellular and Ago2-bound miRNAs in two DLBCL lines were subjected to ultra-deep sequencing (RNA-seq). In the total profiles, 713-851 human miRNAs were detected while the Ago2-immunoprecipitation (Ago2-IP) resulted in 1102-1372 different miRNAs. When a 0.1% cut-off was applied which is considered to yield the functionally relevant miRNAs, only between 56-62 miRNAs were left. These, however, represented 92-95% of all reads. In the two EBV-infected counterparts, EBV-miRNAs represented between 1.6% - 28% of all reads depending on the viral latency type. In the case where EBV miRNAs accounted for 28 % of total reads cellular miRNAs were replaced from the Ago2-complex. The results could be confirmed for selected miRNAs by RT-qPCR and Northern blotting. Also within each cell line, various miRNAs were enriched or depleted from the Ago2 complex. For instance, mir-423-5p and mir-423-3p were highly enriched, by over 6-8-fold in Ago2-IP, compared to total cellular profile in all cell lines while miR142 was strongly depleted from the Ago2-complex indicating a functional loss in DLBCL. The data obtained will help to further understand the contribution of cell and viral miRNAs in induction and maintenance of DLBCL.

1 Introduction

1.1 Lymphoma

Lymphoma is a tumor of lymphocytes, representing almost 5% of all new cancer cases worldwide (MUGNAINI, GHOSH, 2016). Lymphomas are classified into two main groups: Hodgkin's lymphoma (HL), representing about 10% of lymphoma, and non-Hodgkin's lymphoma (NHL), accounting for the remaining 90%. The incidence of NHL is increasing with age and most of the patients are above 65 years old. NHL is categorized into B-cell, T-cell and natural killer (NK) cell types (MUGNAINI, GHOSH, 2016; SHANKLAND et al., 2012).

1.2 Genetics of Diffuse large B-cell lymphoma

Diffuse large B-cell lymphoma (DLBCL) is the most common aggressive subtype of NHL, as it accounts for about one third of all malignant lymphoma cases in adults (MIYAZAKI, 2016). DLBCL is characterized by expressing specific cell surface markers like CD19, CD20, CD22, and CD79a on B-cells. Even though there are different markers for characterizing DLBCL, it is a heterogeneous disease with distinct clinical and biological features. Based on microarray gene expression profiling (GEP), the World Health Organization (WHO) classified DLBCL into three major clusters: (1) Germinal Center B-cell like (GCB), (2) Activated B-cell like (ABC) and cases, which could not be assigned to either group and were therefore, termed unclassifiable (ALIZADEH et al., 2000; CAMPO et al., 2011; ROSENWALD et al., 2002; SWERDLOW et al., 2016). In addition to GEP for classifying DLBCL, next-generation sequencing (NGS), including whole genome and exome sequencing also allows to differentiate the genetic alteration patterns of ABC and GCB (ZHANG et al., 2013).

Germinal centers (GCs) are the sites in secondary lymphoid tissue where B cells proliferate, differentiate and undergo immunoglobulin somatic hypermutation (SHM), class switch recombination (CSR), and affinity selection, to produce high affinity antibodies (VICTORA, NUSSENZWEIG, 2012). Due to the high rate of B cell proliferation and differentiation, germinal center cells can undergo genetic aberration, resulting in lymphomagenesis (BASSO, DALLA-FAVERA, 2015). GCB-DLBCL

originates from germinal center centroblasts, is more common among young people and GEP shows the characteristics of tonic B-cell receptor (BCR) signaling (COPIE-BERGMAN et al., 2002; CUMMIN, JOHNSON, 2016). ABC-DLBCL (often also termed non-GCB), is derived from post germinal center cells. It has been shown that MYC/BCL2 double translocations, amplification of the oncogenic mir-17–92 microRNA cluster, mutations in genes such as BCL2, the proto-oncogene MYC (gain of function), histone methyl-transferase EZH2 (gain of function), S1PR2, GNA13 (loss of function), occur more often in GCB-DLBCL (INTLEKOFER, YOUNES, 2014; ROSCHEWSKI et al., 2014; SWERDLOW et al., 2016). In comparison to GCB-DLBCL, ABC-DLBCL is often characterized by mutations affecting in B-cell receptor signaling, especially the NF- κ B-pathway (COPIE-BERGMAN et al., 2002; CUMMIN, JOHNSON, 2016). ABC-DLBCL is preferentially associated with mutations in genes, such as CD79A, MYD88, CARD11 and TNFAIP3, which activate the B-cell receptor, the Toll-like receptor and also the NF- κ B pathways (BASSO, DALLA-FAVERA, 2015; LENZ et al., 2008; SWERDLOW et al., 2016; ZHANG et al., 2013).

This molecular genetic difference in gene expression profile and signaling pathways, can lead to the conclusion that there is a unique pathogenicity mechanism, differentiating GCB- from ABC-DLBCL, resulting in a different strategy for treatment.

1.3 Clinical genetic diagnosis of DLBCL

A diagnosis of DLBCL is obtained from a tissue biopsy of the enlarged lymph node and assessment of lymph node architecture. Since GEP is not routinely available as the clinical diagnostic test for differentiation of GCB- and ABC-DLBCL, the “Hans algorithm” (Figure 1) has been used frequently with an accuracy of about 90%, and recommended for routine diagnosis. This algorithm is based on immunohistochemistry (IHC) staining, and evaluating the expression patterns of cluster of differentiation (CD10), B-cell lymphoma 6 (BCL6), and interferon regulatory factor-4/multiple myeloma-1 (IRF4/MUM1) expression (HANS et al., 2004; SWERDLOW et al., 2016). Novel methods, such as gene panel (Lymph2Cx assay) from Formalin-fixed paraffin-embedded (FFPE) tissues (SCOTT et al., 2014), NGS,

flow cytometry, cytogenetic analysis using fluorescence in situ hybridization (FISH) or polymerase chain reaction (PCR), for chromosomal translocations or rearrangements of genes, can be considered as alternative medical genetic diagnostic methods, to differentiate various types of lymphoma.

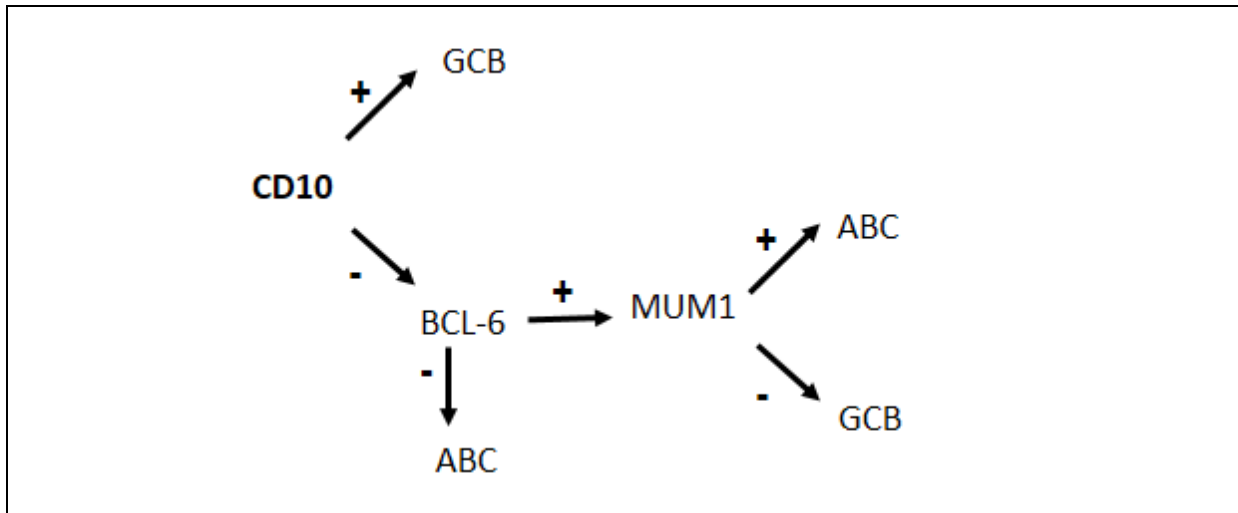

Figure 1: Hans algorithm for differentiation of diffuse large B-cell lymphoma (DLBCL).

Immunohistochemical staining (IHC) to differentiate GCB-DLBCL from non-GCB-DLBCL (ABC-DLBCL). Adapted and modified from (HANS et al., 2004).

1.4 Medical Treatment of DLBCL; future perspective

Diffuse large B-cell lymphoma (DLBCL) is a human malignancy with a very poor prognosis. About 15% of all DLBCLs are EBV positive by virtue of the presence of EBV-transcripts in the tumor cells (DELECLUSE et al., 2007; IMIG et al., 2011). The standard treatment for patients with ABC or GCB-DLBCL is R-CHOP therapy. CHOP is a combination of rituximab, anti-CD20 monoclonal antibody, cyclophosphamide, doxorubicin, vincristine, and prednisone (TOMITA et al., 2013; YU, LI, 2015). As DLBCL constitutes a distinct molecular disease and therefore has a different clinical and prognostic features, it is promising to use novel strategies, based on molecular insights of affected signaling pathway and targeting genes, which are characteristic of GCB- or ABC-DLBCL. For example, targeting BCL-6 to prevent cell proliferation, using an HDAC inhibitor (PAREKH et al., 2008), etoposide to inhibit topoisomerase II (DUNLEAVY et al., 2013; KUROSU et al., 2003) or targeting of *EZH2*, which is

mutated in GCB-DLBCL (BÉGUELIN et al., 2013). In the case of ABC-DLBCL, which has the worst prognosis among DLBCLs, targeting the NF- κ B-pathway to prevent constitutive activation and overexpression of NF- κ B, could have a potential therapeutic effect, such as using ibrutinib, which inhibits BTK in the NF- κ B-pathway (WILSON et al., 2015).

1.5 Molecular genetics of Micro RNA

MicroRNAs (miRNAs) are conserved, short single stranded noncoding RNA molecules of 19-25 nucleotides in length, which are processed from longer hairpin-structured transcripts (Figure 2) (AMBROS et al., 2003; CULLEN, 2004). The main function of miRNAs in the cell is to fine-regulate gene expression. The first miRNA was discovered in Victor Ambros' lab in 1994, where it was shown that the interaction of *Lin 4* with the *Lin14* mRNA in the worm *Caenorhabditis elegans* (*C. elegans*) causes reduction in the amount of LIN-14 protein, resulting in a distinct phenotype. This interaction is important in the timing of the development and transition from the first to the second larval stage (BARTEL, 2004; KIM, 2005; LEE et al., 1993). A few years later, the Ruvkun group found the second small RNA, termed *let-7*, controlling the *Lin41* mRNA. They also demonstrated that this interaction is essential for the transition from larval stage 4 to the adult (REINHART et al., 2000). Most importantly, they also found that a *let-7* homolog exists which is expressed in humans and other species (PASQUINELLI et al., 2000). This important discovery opened a new era in molecular biology to understand the functional importance of miRNAs (AMBROS, 2004; BARTEL, 2004).

1.6 Biogenesis of miRNAs

About 1% of the genes encode for miRNA, and it is estimated that about one third of all human genes might be targeted by miRNAs. MiRNAs are transcribed from either intronic (coding and non-coding), or exonic regions of the genome. The primary transcription is typically several kilobases long, with (a) hairpin structure(s) that contain(s) either one miRNA or a cluster of miRNA hairpin structures, as shown in Figure 2 (BARTEL, 2004; HA, KIM, 2014; KIM et al., 2009).

The key proteins for biosynthesis of miRNAs are two RNase III type endonucleases, Drosha and Dicer, and the “Argonaute” proteins. The region of the genome encoding a miRNA is first transcribed by RNA polymerase II (Pol II), leading to a primary miRNA transcript (pri-miRNA). Subsequently pri-miRNA is recognized and cleaved in the nucleus by the RNase-III endonuclease Drosha, together with the cofactor DGCR8/Pasha. This cleavage creates a hairpin structure about 70-bp length with 2-nucleotide long 3' overhangs at the cleavage site, which is termed precursor miRNA (pre-miRNA) hairpin. Then the pre-miRNA is translocated to the cytoplasm by exportin 5, which is a Ran guanosine triphosphate-dependent (Ran-GTP) dsRNA-binding protein (BOHNSACK et al., 2004; LUND et al., 2004). In the cytoplasm, the pre-miRNA is further processed by the RNase III endonuclease “Dicer”, which results in the formation of ~22-nucleotide mature duplex miRNAs (BARTEL, 2004; HA, KIM, 2014; KRICHEVSKY, GABRIELY, 2009).

Figure 2: Genomic organization of miRNAs.

MiRNAs can be classified into different groups based on their location in the genome. a) MiRNA located in the noncoding region of TU like the miR-15a and miR-16-1 cluster in DLEU2 (non-coding RNA gene). b) MiRNA located in the intron of coding TU for protein such as miR-25, miR-93 and miR-106b cluster in MCM7 transcript. c) MiRNA located in the exon of noncoding TU such as miR-155 in the BIC1 Gene .d) miRNA located in the exon of protein coding regions such as miR-985 in coding region of CACNG8. MiRNA can be transcribed as a polycistronic TU (a and b) or single TU (c and d). TU, transcription unit. Adapted and modified from (KIM et al., 2009).

1.7 RNA-induced silencing complex (RISC) formation

The mature miRNA duplexes are then incorporated into the Argonaute/EIF2C complex. The one strand with less thermodynamic base pairing stability, for instance a GU base pair, as compared to a GC base pair at the 5' end, remains in the Ago complex and forms a functional mature miRNA, termed guide miRNA while the other miRNA strand named passenger miRNA (miRNA*) is released from the Ago-complex and degraded. However, in other cases, like miR-142, both miR-142-3p and miR142-5p, are incorporated into the RISC complex (KWANHIAN et al., 2012). Dicer1 is also believed to associate with Ago2 in this process. Finally, Ago2, Dicer and TRBP (TAR RNA-binding protein or TARBP2) form the miRNA Induced Silencing Complex (RISC),

to silence their mRNA target (Figure 3) (BARTEL, 2004; KIM et al., 2009; LIN, GREGORY, 2015).

Figure 3: miRNA biogenesis.

MiRNA genes are transcribed by RNA pol II into pri-miRNA and then processed by Drosha–DGCR8 to generate the pre-miRNAs. The pre-miRNAs (about 65-70 nucleotides) are recognized by the exportin5 / Ran GTP complex and transferred to the cytoplasm. In the cytoplasm, Dicer (RNase III) further processes the pre-miRNA to generate the mature miRNA duplex. The mature miRNA is loaded into the AGO-GW182 protein complex and forms the RISC complex. Finally the miRNA directs the “Argonaute”-complex to the mRNA gene target to perform the silencing effect. Adapted and modified from (LIN, GREGORY, 2015).

1.8 Mechanism of miRNA-directed regulation

Once the “Argonaute”-complex has been recruited to the 3'UTR of its mRNA target, it interacts with the N terminal domain of the GW182 protein (*Drosophila*) or the TNRC6A (mammalian) protein. GW182 possesses at the N-terminus glycine-tryptophan (GW) amino acid repeats and a crystallographic study showed that two tryptophan residues are important for AGO binding (SCHIRLE, MACRAE, 2012). At the C-terminus, GW182 through a RNA recognition motif (RRM) and a poly(A)-binding protein-interacting motif 2 (PAM2) motif, directly interacts with the PABPC (poly(A)-binding protein C) on the poly(A) tail of the mRNA. GW182 also interacts directly with NOT1 which is a part of CCR4–NOT deadenylation machinery. Recruiting the CCR4–NOT complex to the 3' UTR results in removing and shortening of the poly(A) tail, and also leads to cap removal from mRNA and calling the XRN1 exonuclease and finally degrading the mRNA (MEISTER, 2013).

1.9 The Argonaute proteins

Argonaute (Ago) are the key proteins in the RISC complex. The AGO families are divided into three subclades: PIWI, AGO and WAGO (Worm-specific Argonaute). The PIWI subclade, which has a homology to *Drosophila melanogaster* PIWI, is mainly expressed in the germ line and associated with PIWI-interacting RNAs (piRNAs). The AGO subclade, which is similar to *Arabidopsis thaliana* AGO, is involved in the miRNA or the siRNA pathway (MEISTER, 2013). In humans, four types of the AGO subfamily have been identified, namely **1**) hAGO, EIF2C1 **2**) hAGO2, EIF2C2 **3**) hAGO3, EIF2C3 **4**) hAGO4, EIF2C4. The Ago family is highly conserved, ubiquitously expressed in numerous tissues, and have a molecular weight of approximately 100 kDa (SASAKI et al., 2003; ZHAI et al., 2016). Among the human AGO subfamily, Ago2 is the only protein which possesses the catalytic RNase activity, and has an important role in RNA guided silencing processes. Recently the crystal structures of AGO2 were resolved and it revealed four main domains: an N-terminal domain, a PAZ (Piwi-Argonaute-Zwille), a MID (middle) and a Piwi domain (Figure 4) (ELKAYAM et al., 2012; SCHIRLE, MACRAE, 2012). As shown in Figure 4, these domains form a bi-lobal shape, one lobe with N-terminal domain and PAZ domain and the other lobe with

MID and PIWI domains. These lobes are connected, by Linker 1 (L1) and Linker 2 (L2), in order to form a hinge, connect the two lobes and bond them together. The N-terminal domain is important for loading the RNA duplex and unwinding of miRNA. The PAZ domain binds to the 2-nucleotide of 3' overhang of miRNA. The MID domain provides a binding pocket for the 5' overhang of the guide RNAs, with preferential binding to U or A nucleotides. The PIWI Domain has a homology to RNase H and possesses endonucleolytic activity to slice mRNAs, between nucleotide positions 10 and 11, from the 5' end of the small guide miRNA. Therefore, binding of the small guide RNA at 5' end, to PAZ and MID domain in one hand, and the 3' overhang to PIWI domain on the other hand, cause the small guide miRNA to accommodate in an A-form helix conformation, between two lobes. It also causes exposure of nucleotide 2 to 7 of guide miRNA, termed a seed sequence, and the finding of a complementary sequence of the mRNA target. All human AGO proteins subclades were able to induce translational suppression, degradation of mRNA targets through the formation of the RISC complex. Ago2 is the only Argonaute protein that has the capability to slice perfectly matched mRNA (HA, KIM, 2014; LIU et al., 2004; MEISTER, 2013; PARKER et al., 2005; YE et al., 2015; ZHAI et al., 2016). Ago2 knockdown, using siRNA results in increased expression of other Ago proteins, especially Ago1 and vice versa (MATSUI et al., 2015).

Figure 4: Schematic depiction of the Ago2 protein.

a) Ago2 consists of an N terminal domain, a PAZ domain (binds to 3' guide miRNA), the MID (middle) and the PIWI domain (binds to the 5' monophosphate of the guide miRNA). The numbers indicate location of each domains in Ago2. b) 3D structure of human AGO2 with guide miRNA in red color. Adapted and modified from (ELKAYAM et al., 2012; HA, KIM, 2014)

1.10 MicroRNAs in cancer

Since the discovery of miRNAs by Victor Ambros in developmental timing in *C. elegans*, the function of miRNA was extended to their contribution to cancer. We now know that miRNAs can act as oncogenes (oncomiRs), by inducing different mechanisms such as cell proliferation, migration and invasion, tumor growth and metastasis, or act as a tumor suppressor by inhibiting cell proliferation, migration and invasion (LEE et al., 2016). The most common molecular genetic changes in miRNA expression levels are as follows:

1) Downregulation of miRNA processing enzymes, such as a) Drosha by inducing expression of the oncogenic transcription factor c-MYC or RNA-specific deaminase

ADARB1, which results in the reduction of pri-miRNA processing and downregulation of the tumor suppressor microRNAs MiR-15/-16 (ALLEGRA et al., 2014). b) Dicer downregulation by different mechanisms, such as downregulation or loss of function of transcription factor TAp63 (binds to the promoter of Dicer), or by miRNA-mediated downregulation such as let-7 (TOKUMARU et al., 2008), miR-103/107 (MARTELLLO et al., 2010), and miR-630 (RUPAIMOOLE et al., 2016). c) Induced ago2 phosphorylation at Tyr₃₉₃, by the epidermal growth factor receptor (EGFR), which affects binding of Ago2 to Dicer, during hypoxia leading to reduced miRNA processing (SHEN et al., 2013). d) Mutation in the exportin 5 encoding gene, leading to decreased transport of miRNA from the nucleus to the cytoplasm, which induces expression of the *EZH2* and the *MYC* oncogene (MELO et al., 2010; RUPAIMOOLE, SLACK, 2017).

2) Downregulation of tumor-suppressor miRNAs such as a) the miR-34 family including miR-34a, miR-34b and miR-34c. b) the let-7 family (consisting of ten isoforms), involved in targeting many oncogenic mRNAs, like *KRAS* in the RAS signaling pathway, c) the miR-200 family such as miR-200a/b/429 and miR-200c/141, involved in epithelial–mesenchymal transition (EMT), which is important for metastasis and invasiveness of cancer cells (DE CRAENE, BERX, 2013), d) miR-15/16 located on chromosome 13q14, which is lost in B-cell chronic lymphocytic leukemia (CLL) and targets BCL-2 expression (PEKARSKY, CROCE, 2015), e) miR-506 inducing senescence by targeting CDK4 and CDK6 proteins (LIU et al., 2014) and targeting *RAD51*, a double-strand DNA damage repair gene, in ovarian cancer (LIU et al., 2015a), f) miR-520 (RUPAIMOOLE, SLACK, 2017).

3) Molecular genetic alterations such as a) chromosomal deletion, for example, deletion(s) in the 13q14 chromosome, which is normally lost in B cell chronic lymphocytic leukemia (B-CLL), containing tumor suppressor miR-15 and miR-16 (CALIN et al., 2002). b) Chromosomal amplifications such as amplification of the 17q23.2 chromosomal region, which contains the oncogenic mir-21, deregulated in many types of cancer (breast, lung, gastric, ovarian and prostate cancers) (KRICHEVSKY, GABRIELY, 2009) or amplification of the miR-17-92 cluster family on chromosome 13q 31.1, which is amplified in B cell lymphoma (MENDELL, 2008; RUPAIMOOLE, SLACK, 2017).

1.11 Epstein - Barr Virus (EBV)

The Epstein–Barr virus (EBV), a human tumor virus, was discovered in 1964 by Antony Michael Epstein, Bert Achong and Yvonne Barr, using biopsy material of Burkitt's lymphoma (BL) patients (EPSTEIN et al., 1964). It is estimated that more than 95% of the adult human population are seropositive for EBV infection. In the infected individual, EBV persists probably without any gene expression in CD19⁺ memory B-cells, where it is occasionally reactivated, and shed through the oropharynx into the saliva (THORLEY-LAWSON, 2001). Although the viral infection usually occurs without symptoms in the infected individual, EBV can induce tumors under certain conditions. EBV is responsible for approximately 1.8% of cancer deaths worldwide (DE MARTEL et al., 2012; KHAN, HASHIM, 2014; YOUNG et al., 2016).

1.12 EBV latent genes and transformation

EBV is a γ -herpesvirus with a double-stranded DNA genome of approximately 172 kilobase pairs in length, encoding about 90 genes (KIEFF , RICKINSON 2007; SAMPLE et al., 1990; TASHIRO, BRENNER, 2017). The oncogenic potential of EBV is readily observed *in vitro* by transformation of resting B-cells into permanently growing lymphoblastoid cell lines (LCLs). These LCLs are correlated *in vitro* with the so-called “Post-Transplant Lymphoproliferative Disease” (PTLD), observed under immunosuppression (DELECLUSE et al., 2007). EBV growth-transforms infected B cells by expressing a set of viral proteins, termed latent proteins including six EBV nuclear antigens (EBNA1, -2, -3A, -3B, -3C and –LP), and three membrane proteins (LMP1, 2A and 2B), (Table1). In addition to these nine proteins, EBV expresses two non-coding RNAs (EBER1 and EBER2), and 44 viral miRNAs (Figure 5) (GRUNDHOFF et al., 2006; PFEFFER et al., 2004). During latency, the EBV lytic cycle replication is usually repressed by different mechanisms, such as upregulation of important transcription factors like STAT3 (Signal transducer and activator of transcription 3) in BL or LCL cells. STAT 3 upregulation can affect several Zn-finger repressors, such as ZNF253, ZNF257, SNF589 and SETDB1. Koganti *et al.* have shown a decline in B cells proliferation, when B cells from patients with hypomorphic

mutations in STAT3, are infected with EBV (KOGANTI et al., 2014; LIEBERMAN, 2015). However, lytic cycle reactivation more likely occurs when the EBV-CD19⁺ memory in B-cells is recalled (LAICHALK, THORLEY-LAWSON, 2005; MIYASHITA et al., 1995). It has been shown that EBV lytic cycle can be induced, by activation of transcription factor BZLF1 or other proteins such as X-Box-binding protein 1 (XBP-1) and protein kinase D (PKD), which has an important role in switching from latency to lytic cycle, during EBV infection (BHENDE et al., 2007; COUNTRYMAN, MILLER, 1985; YOUNG et al., 2016) .

Table 1: Different stages of EBV latency.
 Different EBV latency stages are associated with different tumors. Adapted and modified from (HEALY, DAVE, 2015).

Latency Stages	Expressed EBV protein	Associated Tumors
I	LMP2A, EBNA1	Burkitt lymphoma DLBCL NOS T cell-rich DLBCL
II	Protein in latency I + LMP1,LMP2B	Classic Hodgkin's lymphoma Angioimmunoblastic T cell lymphoma NK/T cell lymphoma, N Nasopharyngeal carcinoma Gastric carcinoma
III	Protein in latency II + LP,EBNA2,EBNA3A, EBNA3B,EBNA3C	Primary EBV infection Post-transplant lymphoproliferative disease AIDS-related lymphomas (plasmablastic DLBCL, primary CNS lymphoma, primary effusion lymphoma) EBV + DLBCL of the elderly

1.13 EBV miRNAs

EBV was the first human DNA virus identified to encode miRNAs (PFEFFER et al., 2004). EBV miRNAs are encoded in two clusters, the so-called BHRF1-cluster (Bam HI fragment H rightward open reading frame 1), which encodes 3 miRNAs and the BART-cluster (Bam HI-A region rightward transcript), encoding 41 miRNA (YOUNG et al., 2016). It has been shown that EBV miRNAs are important for keeping EBV in latency by targeting EBV proteins, such as BART(1-5p,16,17-5p), downregulating the LMP1 protein (LO et al., 2007), BART-2, downregulating the DNA polymerase BALF5 expression (BARTH et al., 2008) and BART22, downregulating LMP2A (LUNG et al., 2009). EBV miRNAs also have been shown by many research groups to target cell mRNAs and downregulating their protein expression. For instance, BART1 targets the tumor suppressor phosphatase and tensin homolog (PTEN) (CAI et al., 2015), BART3 and BART16 target IPO7 and TOMM22, respectively (DÖLKEN et al., 2010), BART9 targets E-Cadherin (HSU et al., 2014) and BART6 targets Dicer (IIZASA et al., 2010; KANDA et al., 2015).

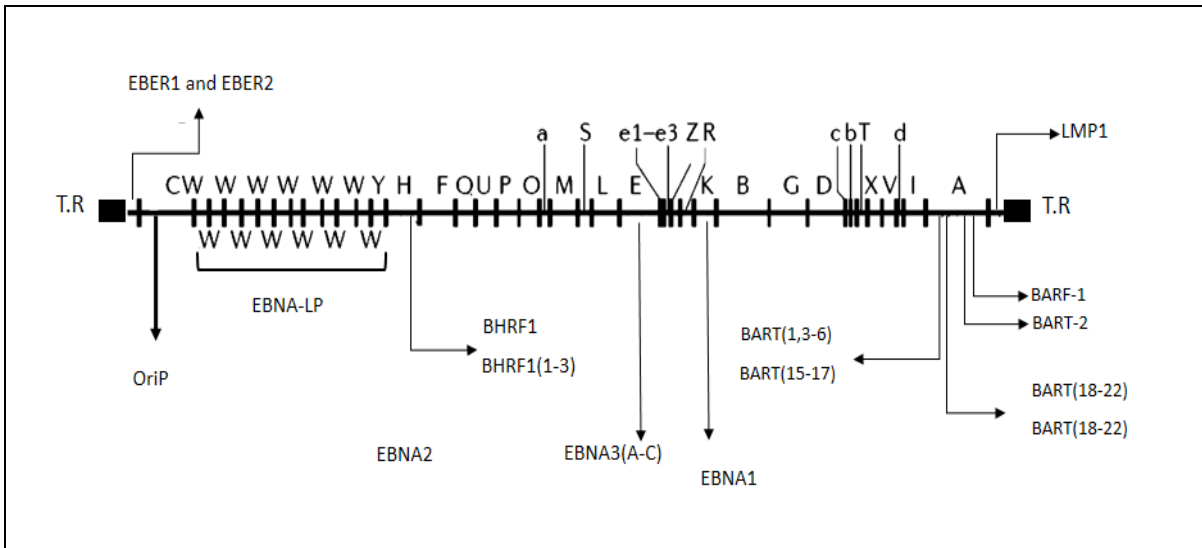

Figure 5: EBV BamHI restriction map.

BamHI restriction maps for the EBV B95-8 strain and locations of latent cycle proteins and the EBV encoded miRNAs. The BamHI fragments are shown according to size using alphabetical letters, a capital letter A for the largest and small letter for the smaller fragment in descending order. TR, terminal repeats are shown as black blocks. BART, BamHI-A rightward transcript, (BHRF1) BamHI fragment H rightward open reading frame, (BARF1) BamHI-A fragment rightward reading frame, (LMP) latent membrane proteins, EBNA (Epstein–Barr nuclear antigens). Adapted and modified from (YOUNG et al., 2016).

1.14 Aim of the study

A very promising approach to understand the involvement of a certain miRNA in the process of a disease such as cancer, is to assess the miRNA expression profile of cancer patients. The comparison with their normal counterpart is a very promising approach for understanding the involvement of (a) certain miRNA(s) in a disease of interest. This may lead to the discovery of a novel prognostic or diagnostic biomarker. Although it is believed that the miRNA profile from extracted total cellular RNA is an actual indicator of RISC complex-associated miRNA, due to quick degradation of non-guide miRNA, this hypothesis was challenged by the Cullen group, when they compared the miRNA profile of the total cellular miRNAs with the RISC associated miRNAs (Ago-IP) pool. Intriguingly, they have found that the total cellular miRNA profile differs from the Ago-bound profile, and therefore they challenged the idea that the total cellular miRNA profile is accurately reflecting the Ago RISC-associated miRNAs (FLORES et al., 2014).

The effect of EBV infection and dysregulation of the total cellular miRNA profile in DLBCL was reported by many researchers, as already discussed above. To the best of our knowledge, this is the first time that Ago2 immunoprecipitation was performed, followed by sequencing (Ago2-IP-seq) in two different DLBCL cell lines and their EBV infected counterparts, in order to profile the miRNAs according to their functional level. The U2932 and SUDHL5 cells and their EBV infected counterparts were used as a model for ABC-DLBCL and GCB-DLBCL, respectively.

The questions addressed in this project were as follows:

1. Determination of differentially expressed miRNA in DLBCLs cell lines, in comparison with their EBV infected counterparts.
2. Assessment of various expressed miRNA, in Ago2-IP in DLBCLs cell lines in comparison to EBV infected counterparts.
3. Evaluation of enriched or depleted miRNA in the Ago2-IP, compared to the total cellular miRNA profile in each cell line by RNA-seq.

2 Materials and Methods

2.1 Material

2.1.1 Laboratory equipment's.

Adjustable pipettes	Gilson, Peqlab
Agilent 2100 Bioanalyzer	Agilent (Santa Clara, USA)
Centrifuge	Megafuge 1.0 R (Heraeus)
Centrifuge	202 MK (Sigma)
Centrifuge 1-16K	Sigma
Chemidoc XRS system	Bio-Rad
CO2 incubator	Heracell™ 150i (Thermo Scientific)
Electrophoresis power supply	Consort EV-231 (Consort bvba)
Electrophoresis power supply	Phero Stab 300 (Biotec Fisher)
Heat block	Thermomixer Compact (Eppendorf)
Oven for hybridization	UM 400B Hyp (Bachhofer)
Phosphoimager	Phosphoimager™-Typhoon with plates and cassettes for exponation (Molecular Dynamics, Amersham)
Photometer	NanoDrop™ 2000c (Peqlab)
Plates (MicroAmp® Fast Optical 96-Well Reaction	(Carlsbad, USA)
Real-Time PCR System (StepOnePlus™); 96-Well	Applied Biosystems/Life Technologies
Semi-Dry Blotter	2117 Multiphor (LKB Bromma)
Shaker	Thermomixer Compact (Eppendorf)
Shaker	POLYMAX 1040 (Heidolph)
Shaker	REAX 2000 (Heidolph)
Shaker	Edmund buehler
Tank-Blotting chamber	2005 Transphor Electro Blotting Unit (LKB Bromma)
Vortex	Heidolph
Weighing balance	Sartorius

2.1.2 Reagents and chemicals

3-Mercapto-1,2-propandiol	Sigma
Ammonium persulfate (APS)	Serva
Bisacrylamide 2%	Roth
Blocking reagent	Boehringer
Blue protein standard	Biolabs
Bovines Serumalbumin (BSA)	Serva
Bradford-Reagent Roti®-Quant	Carl Roth
Bromophenol blue	Serva
``Complete Mini ``Protease Inhibitor Cocktail	Roche Diagnostics
Coomassie Brilliant Blue R 250	Roch
Denhardt's solution 50x	Sigma
Diethylpyrocarbonate (DEPC)	Sigma
EDC-Hydrochlorid	Sigma
Ethanol	Roth
Ethylendiamintetraacetat (EDTA)	Serva
Fetal calf serum (FCS)	Gibco
G 418 (Geneticin)	Invitrogen
Gamma P-32 UTP	Hartmann Analytics
Glycin	Sigma
H ₂ O ₂ 30%	Merck
Hybond™-N membrane	GE healthcare life science Amersham
IGAPEL CA 630	Sigma
KCL	Merck
Klenow Fragment (DNA Polymerase I)	Klenow Fragment (EP0051)
Luminol(3-Aminophthalhydrazide)	Sigma
Magnesium chloride hexahydrate	Roth
Methanol	Roth

Methylimidazole	Peqlab
TEMED	Serva
NaCl	Merck
Nitrocellulose membrane protran 0.2 µM	GE healthcare life science Amersham
Neubauer chamber	C-Chip Neubauer Improved , Digital Bio
Nucleotides (dNTPs)	Peqlab
Nucleotides (NTPs)	Invitrogen
P-coumaric acid	Sigma
pH meter Hydrus 300	Fisherbrand Hydrus 300

Washing buffer I (for NB)	SSC	5x
	SDS	1%
Washing buffer II (for NB)	SSC 1X	
	SDS 1%	

2.1.6 Cell lines

The following cell lines have been used in this study:

U2932: a B-cell line, derived from a patient with HL followed by the NHL, and it has a characteristic of post-GC derived origin (ABC-DLBCL) of the tumor cells (AMINI et al., 2002).

U2932 EBV positive clone A: a U2932 cell line, infected with EBV-GFP, not expressing EBNA2 (BOCCELLATO et al., 2007).

SUDHL5: a B-cell line, derived from a lymph node of a 17-year-old woman with B-cell non-Hodgkin lymphoma (B-NHL) and has characteristic of GCB-DLBCL.

SUDHL5 EBV positive: SUDHL5 cell line, infected with EBV-GFP, obtained from Prof. Pankaj Trivedi, University of Rome.

2.1.7 Primers for real time PCR

The following Primer sequences were ordered from Qiagen for RT-qPCR analyses:

Primer	Sequences	Cat. No.
let-7c-5p	UGAGGUAGUAGGUUGUAUGGUU	MS00003129
miR-10a-5p	UACCCUGUAGAUCCGAAUUUGUG	MS00031262
miR-146a-5p	UGAGAACUGAAUCCAUGGGUU	MS00003535
miR-155-5p	'UUA AUGCUAAUCGUGAUAGGGGU	MS00031486
miR-15a-5p	UAGCAGCACAUAAUGGUUUGUG	MS00003178

miR-363-3p	AATTGCACGG TATCCATCTG TAcctgtctc
miR-423-5p	TGAGGGGCAGAGAGCGAGACTTTcctgtctc
miR-4485-3p	TAACGGCCGCGGTACCCTAAcctgtctc
miR-4792-5p	CGGTGAGCGCTCGCTGGCacctgtctc

2.2 Methods

2.2.1 Cell culture

The U2932, SUDHL5, U2932 (EBV positive), SUDHL5 (EBV positive) cell lines were maintained in RPMI 1640 medium at 37 °C in a 5% humidified CO₂ incubator. RPMI 1640 was supplemented with 10% fetal calf serum, antibiotic mix (40 IU/mL penicillin, 50 µg/mL streptomycin, 1 IU/mL Neomycin-sulfate, 90 IU/mL Nystatin). An additional 200 mg/mL G418 (Geneticin) was used for EBV positive cell lines.

2.2.2 Cell counting (Hemocytometer)

The Neubauer Improved C-Chip was used to count the number of cells. Depending on the cell density, a 1:5 or 1:50 dilution was made in PBS and 2 to 4 outer big squares were counted.

Cell density (cells/mL)

$$= ((\text{No. of counted cells}) : (\text{No. of large Squares})) \times 10^4 \times \text{Dilution factor.}$$

2.2.3 RNA related techniques

2.2.3.1 RNA isolation

Suspension cells (5 to 10 mL) were harvested by centrifugation at 500 x g for 5 minutes at room temperature (RT). 700 µL of Qiazol (Qiagen) was added to the pellet and incubated for 5 min at RT. Afterwards, 125 µL of chloroform was added to the sample and vortexed for 15 sec, and subsequently again incubated for 10 min at RT. the sample was then centrifuged at 12000 xg for 15 min at 4 °C and the upper phase was transferred to a new 1.5 mL microcentrifuge tubes and 500 µL of isopropanol was added to the tube and incubated on ice for 15 min, followed by centrifugation at 12000 xg for 30 min in 4 °C . After that, the pellet was air dried at RT for 15 min and dissolved in 50 µl of RNase free H₂O and the RNA was dissolved by incubation at 55 °C for 15 min.

RNA isolation for sequencing, qRT –PCR and Ago2-IP for NB was performed using the miRNeasy Mini kit (Qiagen) according to manufacturer's instructions. Briefly, 700 μ l of QIAzol was added to 100 μ l of cell lysate or directly to the beads, after the last washing step with PBS (Ago2-IP and control-IP). Then the mixture was vortexed and incubated at room temperature for 5 min. Centrifugation was performed at 12000 xg for 15 min at 4°C. Then the upper aqueous phase transferred to a new collection tube. Subsequently, 1.5 volumes of 100% ethanol were added and mixed by pipetting up and down few times, and the mixture was loaded on the spin column in a 2 mL collection tube. Next, the samples were centrifuged at 12000 xg for 1 min the supernatant discarded and this step was repeated, until all the solutions were loaded on the column. The column was washed once with 700 μ l RWT buffer and twice with 500 μ l RPE buffer. All centrifugations were performed at 12000 xg for 1 min, and finally the column was transferred to a new collection tube. The RNA was eluted in 30 μ l of RNase-free water by centrifuging at 12000 xg for 2 min. Tumor specimens from DLBCL patients were extracted from snap-frozen tissues using TriZol instead of Qiazol, as described above. The concentrations of all extracted RNAs, were measured by NanoDrop, and samples were stored at -70 °C.

2.2.3.2 MiRNA microarray and data analysis

MiRNA expression profiling of 1205 human miRNAs and 44 EBV miRNAs was performed in triplicate using the Agilent human miRNA microarray (release 16.0, Agilent, Cat. No, G4870A). Briefly, 100 ng of isolated RNA from total lysates or immunoprecipitates from U2932 or U2932-EBV cell line was dephosphorylated, labelled with pCp-Cy3 and hybridized to the microarray according to the manufacturer's instructions.

Microarray data analysis was performed as described (LUDWIG et al., 2015). In brief microarrays were scanned using the Agilent Microarray Scanner and expression values were extracted with the Agilent Feature extraction software. Raw data of cellular input and immunoprecipitate arrays was quantil normalized separately using R software. Unpaired two-sided t-tests were performed. For identification of significantly differentially expressed miRNAs between U2932E-EBV vs. U2932 cell lines for total lysates and immunoprecipitates, two-fold changes and P-values of <0.05 were considered statistically significant.

2.2.3.3 MiRNA sequencing and processing of data

Sequencing was performed by next generation sequencing (IKMB, University of Kiel) using total cellular lysate and purified RNA from U2932, SUDHL5 and the EBV positive counterpart using TruSeq small RNA Library Type on the HiSeq 2500 system from Illumina. The analysis of sequencing data was performed by Tobias Fehlmann under the guidance of Prof.Dr. Andreas Keller (Chair for Clinical Bioinformatics, Saarland University). Briefly, the miRMaster tools was used to remove the trimmed adaptors and to quality filter the reads (FEHLMANN et al., 2017). Then the Bowtie sequence alignment software was used to map with Genome Reference Consortium GRCh38 (hg38) with one mismatch pairing allowed (LANGMEAD et al., 2009). Those reads which mapped with hg38 were used for human miRNA quantifications and those which are not mapped to human genome were used for EBV miRNA. miRBase (v21) (KOZOMARA, GRIFFITHS-JONES, 2014) and the miRMaster tools were used for mapping of miRNA for human and EBV miRNA.

2.2.4 qRT-PCR

Quantitative Real Time-PCR (qRT-PCR) was performed to validate the NGS data using the miScript II RT Kit and the miScript SYBR Green PCR Kit on the StepOnePlus™ Real-Time PCR System.

2.2.4.1 Reverse Transcription to generate cDNA for qRT-PCR

The extracted RNA was converted to cDNA in the following reaction:

Components	Volume
5x miScript HiSpec Buffer	4 µL
10x miScript Nucleic Mix	2 µL
RNase free water	11µL
miScript Reverse Transcriptase Mix	2 µL
Template RNA	200 ng for total cellular and 20 ng for Ago2 IP RNA extract (1 µL)

The reaction mixture was incubated for 60 min at 37°C, followed by 5 min at 95°C to inactivate miScript Reverse Transcriptase. The reaction was diluted 1 to 10 in RNase-free H₂O, and the samples were stored at -20 °C until further use. qRT-PCR reaction was performed in duplicate and miR-30d was used as an endogenous control as our NGS data showed no expression difference of human miR-30d between U2932 and SUDHL5 cell lines and the EBV positive counterparts in total cell lysates or Ago2-IP miRNA profile. Fold change in EBV negative versus EBV infected DLBC cell lines was calculated by the following formula for cellular input and Ago2-IP:

$$\text{Fold change difference} = 2^{((\text{miR-XEBVneg} - \text{miR-30dEBVneg}) - (\text{miR-XEBVpos} - \text{miR-30dEBVpos}))}$$

To define if a miRNA was deregulated two criteria applied to our data:

- 1) At least 2-fold expression difference between EBV negative and positive counterpart.
- 2) qRT-PCR result in the same direction as in the sequencing results.

The following cycling program was used for StepOne instrument:

Components	Volume
cDNA-Template (1:10 diluted)	2 μ L
2x QuantiTect SYBR® Green PCR Master Mix	5 μ L
10x miScript Universal Primer	1 μ L
10x miScript Primer Assay	1 μ L
H2O RNase-free	1 μ L

PCR Initial activation step	95 °C	15 min
3-step cycling:		
	94 °C	15 s
	55 °C	30 s
	70 °C	30 s

2.2.4.2 Northern blot for the Analysis of the miRNA

Northern blot is a technique used to detect a specific RNA in a sample. This technique was performed to compare and validate significantly deregulated miRNA from NGS and qRT-PCR data in total cellular lysate and Ago2-IP data.

Equal amounts of extracted RNA from total cellular (15 -20 µg) or Ago2-IP and isotype control (200 ng of purified RNA), were mixed with 5 µl RNA loading buffer, and loaded on a 12% urea polyacrylamide gel. The gel was run at 20W for 3 to 4 hours in 1X TBE buffer. To check the loading control and the quality of RNA, the gel was stained with ethidium bromide (10 µg in 100 mL 1X TBE) for 5 min and the RNAs were visualized at 254nm. The ethidium bromide picture was documented, using ChemiDoc XRS (Bio-Rad). An equal amount of 1.5 µg RNA, from DLBCL and lymph nodes of patient samples was loaded for Northern blot.

Composition of 12% of a Urea polyacrylamide gel

Components	Volume
UreaGel 29:1 Concentrate	24 mL
UreaGel Diluent	21 mL
UreaGel Buffer	5 mL
TEMED	20 µl
APS 10%	400 µl

2.2.4.3 Transfer of RNA to a Membrane

To transfer the RNA to a nylon membrane (Hybond N; Amersham), an electroblot transfer sandwich was set up as follows: five pre-wet Whatman papers with dH₂O, nylon membrane, gel, five more pre-wet Whatman paper. Transfer was carried out at 15V for 30 minutes, using a semi-dry chamber with transfer from anode to cathode. Following the transfer the membrane, on top of three Whatman papers, soaked in freshly prepared EDC crosslinking reagent and then the NB membrane was wrapped in Saran-Wrap and incubated at 60 °C for 1 to 2 hours. Following crosslinking, the membrane was transferred to a glass tube and incubated with 30 mL pre-hybridization buffer with continued rotation at 50 °C for 30 min. Then the ³² P-labeled miRNA probe

(see below) was added to the hybridization buffer, and incubated overnight with a continued rotation at 50 °C, in an oven. The next day the membrane was washed two times with 5XSSC and two times with 1XSSC (each time about 20 min). The membrane was wrapped with Saran-Wrap and exposed to Phosphorimager, and the next day scanned with the Phosphorimager TM Typhoon.

2.2.4.4 Generating radiolabelled ³²P RNA probe

To generate radiolabelled ³²P RNA probes a two-step procedure was used. First a double strand DNA template from a single stranded oligonucleotide which has a CCTGTCTC AT at 3' end (complementary to T7 promoter sequence) was generated using the mirVANA TM kit. In second step the ³²p RNA probe was generated from the double stranded template.

Double strand DNA (dsDNA) template synthesis;

a) The following components were incubated at 70 °C for 5 min and then at RT for 5 min.

Components	Volume
H2O	6µL
T7-Promoter Primer (100µM)	2µL
Oligonucleotide Template (100 µM)	2µL

b) To complete the reaction, the following components were added and this mixture was incubated at 37 °C for 30 min. The prepared double strand DNA template for miRNA of interest was stored at -20 °C until use.

Components	Volume
Nuclease-free H2O	4 µl
10 x Klenow buffer	2 µl
10 x dNTPs	2 µl
Exo-Klenow	2 µl

2. Generation of ³²P RNA probe at radioactive lab

Components	Volume
Nuclease free H ₂ O	7 µl
dsDNA template	2 µl
NTPs(without U)	3 µl
10 x RNA polymerase buffer	2 µl
T7-RNA polymerase	2 µl
³² P -labeled UTP (radioactive)	5 µl

After adding the above components, the mixture was put on continuous shaker (700RPM) for 10 min at 37 °C and then 1 µl of DNase I was added and again put on continuous shaker (700 RPM) for 10 min at 37 °C, and finally as discussed the prepared probe was added to the glass tube containing hybridization buffer and cross-linked NB membrane.

2.2.4.5 NB stripping

To re-probe the NB membrane with a different ³²p-labelled probe, the previous signal was removed using stripping buffer. The membrane was put into a glass tube and incubated with warmed stripping buffer, for one hour at 70°C in the oven under continuous rotation. After removing the stripping buffer, the membrane was wrapped with a Saran-Wrap and exposed to the phosphor imager overnight (Phosphorimager TM Typhoon) to ensure that the previous signal was erased.

2.2.5 Protein related techniques

2.2.5.1 Immunoprecipitation and immunoblotting of Ago2 – IP

To perform the RISC associated miRNA profiling, the Ago2 Immunoprecipitation was carried out as described previously (DEMBLA et al., 2014; DOLKEN et al., 2010). The cell lines, either U2932 or SUDHL5 or the EBV positive counterparts were cultured, in large scale (400 to 500 mL) in RPMI1640, supplemented with 10% FCS and antibiotics (see material and methods). After counting the cells, about 3.5×10^8 cells were used for each IP (3). Antibody coupling was performed one day before performing IP. For coupling, about 200 μ L of Sepharose Protein G beads were washed 3 times with cold PBS buffer (at 500 xg for 3 min), and then at the last step the supernatant was removed and the pellet divided into two tubes. In each tube, about 100 μ L of Sepharose Protein G beads was incubated overnight with 1.6 mL monoclonal antibody, Ago2 antibody 11A9 (rat IgG2a) or with isotype control (rat IgG2a) antibody, on vertical rotator at 4°C. The next day the beads were washed three times with PBS, and once with lysis buffer before incubating with lysate. For Ago2-IP, about 3.5×10^8 cells from U2932, SUDHL5 and their EBV positive counterparts, were pelleted and washed three times with PBS (at 500 xg for 3 min). Then, 1.5 mL of lysis buffer were added to the pellet in 1.5 mL reaction tube, and incubated for 30 min on the vertical rotator at 4°C. Subsequently, the tube was centrifuged at 20,000 xg for 30 min at 4°C. Afterwards, to decrease the non-specific binding, the lysate was precleared with 100 μ L of protein G-Sepharose beads (washed 3 times in PBS) alone for 60 min at 4°C, using a vertical rotator. Next, samples were centrifuged at 20,000 xg for 5 min at 4°C. 100 μ L of the cleared lysate was removed for preparing total RNA, and 50 μ L as a protein input. The remaining lysate was divided in two equal volumes for the Ago2-IP and the isotype control-IP experiment and the volumes were adjusted to 1 ml with lysis buffer. The coupled beads were incubated with the lysis buffer overnight on a vertical rotator at 4 °C.

The next day, the beads were pellet down at 500 xg for 3 min at 4 °C, and washed three times with wash buffer (50 mM Tris HCl, pH 7.4, 300 mM KCl, 1mM MgCl₂, 0.5% IGEPAL) and once with PBS. 25 μ L of each immunoprecipitated fraction was removed

and this sample was used to check the efficiency of Ago2 IP, by Western blot (GROSS et al., 2010) and the remaining beads was incubated with 700 μ L Qiazol reagent (Qiazol, Hilden, Germany), followed by RNA extraction, using the miRNA easy kit.

2.2.5.2 SDS-PAGE

Sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE), is used to separate proteins according to the molecular mass, under denaturing conditions. SDS-PAGE was performed as described by Laemmli, 1970; Sambrook et al., 1989. Before loading the samples, either the lysate or immunoprecipitated fractions from different cell lines were diluted in 4X SDS loading buffer and heated for 6 min at 94°C. Three μ l of molecular mass marker proteins were also separated on the gel. SDS-PAGE was carried out at 80V (stacking gel) and 125 V (separating gel), for about 3.5 hours.

2.2.5.3 Western Blot

Following SDS-PAGE, the proteins were transferred to a nitrocellulose membrane by electrophoresis, at 400 mA for 3 hours at 4°C. After blotting, the membrane was stained with Ponceau S, to ensure that the transfer was carried out properly. The membrane was destained with PBS for 15 min under agitation and then blocked with 5% nonfat dry milk in PBS for 75 min under agitation at room temperature. Subsequently, the membrane was incubated with the indicated primary antibody, overnight at 4 °C. The membrane was washed 3 times with PBS, for about one hour, and then incubated with appropriate secondary antibody(conjugated with horseradish peroxidase), in blocking reagent (5% milk in PBS) for 2 hour under agitation at 4 °C. The membrane was washed 3 times with PBS for about one hour at room temperature. Finally, the membrane was developed using ECL (see Material and Methods part) and documented with the Bio-Rad Gel-Doc apparatus, using the Quantity One (Bio-Rad) software.

3 Results

Here we tested (i) the miRNA profiles of the DLBCL cell lines U2932 and SUDHL5 and their EBV-converted counterparts U2932-EBV and SUDHL5-EBV , (ii) the miRNA profiles of the Ago2-complex of four cell lines, and(iii) whether the EBV-infection would alter the loading of the Ago2-complex. Previous work had shown that the overall miRNA profiling of a cell line did not necessarily reflect the function of a given miRNA as the Ago-loading might be very different from its overall content in the cell (FLORES et al., 2014).

In the following, we refer to the sequencing of cellular miRNA as “Total” and to the miRNA obtained from the Argonaute 2 immunoprecipitation as “Ago2-IP”.

3.1 Characterizations of cell lines

The type of EBV latency was determined by Western blot with antibodies against EBNA1, LMP and EBNA2, using U2932-EBV and SUDHL5-EBV cellular extracts. As shown in Figure 6, SUDHL5-EBV has the characteristics of type III EBV-latency as it expresses EBNA1, LMP and high amounts of EBNA2. In contrast, U2932-EBV clone A has the characteristics of type II latency, as it express EBNA1 and LMP1 but low amounts of EBNA2.

3.2 Microarray results

The isolated RNA from the Ago2-IP in U2932 and U2932-EBV, was analyzed by microarray. In addition, the RNA was isolated from the total cellular lysate to determine the miRNA profile prior to precipitation. Two replicates of the total cellular fraction failed the array quality control and were therefore excluded (marked as None Applicable (NA) from the study. the summary of the microarray data is shown in Table 2. We detected 206 miRNAs in U2932-EBV, and 170 miRNAs in the U2932 cell line. Of the total cellular miRNAs, detectable in both cell lines, nine were significantly upregulated (≥ 2) and 14 were significantly downregulated (≤ 2), in U2932-EBV compared to the U2932, respectively. Data are presented in Table 3 with the expression level taken into account. In the Ago2-IP, 386 miRNAs were detected in the U2932-EBV, and 395 in the U2932 cell line. In comparison with the Ago2-IP profile of U2932-EBV vs. U2932, 15 miRNAs were upregulated, while 169 miRNAs were downregulated. A complete list of up and downregulated miRNAs is shown in the appendix (Table A9).

Table 2: Summary of miRNAs detected by microarray, in “Total” and “Ago2-IP” profile in U2932-EBV and U2932.							
No. of miRNAs	Replicate1	Replicate 2	Replicate 3	Replicate 4	Mean	St dev.	Summary
Total cellular profile U2932-EBV	219	219	208	NA	215.33	6.35	206
Total cellular profile U293	182	190	163	NA	178.33	13.87	170
Ago2_IP U2932-EBV	413	408	388	392	400.25	12.12	386
Ago2_IP U2932	417	409	397	408	407.75	8.22	395

3.3 Sequencing results

In order to investigate the miRNAs that were differentially associated with Ago2-complex, in comparison to the total cellular miRNA profile, and to determine whether EBV infection changes the loading of miRNA in the RISC complex, we performed Ago2 immunoprecipitation (Ago2-IP), in extracts from the uninfected DLBCL cell lines (U2932, SUDHL5) and their EBV infected counterparts (U2932-EBV, SUDHL5-EBV). The RNAs from the Ago2-IPs and from the total cellular extracts were subjected to next generation sequencing (NGS).

The specificity of the Ago2-IPs was determined from an aliquot of the precipitate, before the RNA was subjected to sequencing. As shown in Figure 7, the Western blot of the Ago2-IP demonstrated that the Ago2 protein was successfully precipitated from all four cell lines, and that the controls did not contain Ago2-protein

Figure 7: Immunoprecipitation of Ago2 from U2932, SUDHL5 and their EBV positive counterparts.

Extract of the indicated cell lines was precipitated with Ago2 specific antibody (11A9) and an appropriate isotype control antibody. The membrane was first stained with Ago2 and then with mouse-anti rat IgG coupled to horseradish peroxidase as a secondary antibody. The precipitated Ago2-protein was visualized by the ECL method. The molecular mass marker proteins (in kDa) and the position of Ago2 are indicated by bars to the left side of the blot.

The overall results from the total cellular profiling and the Ago2-IP are shown in Table 4. We obtained about $8.7\text{-}15.3 \times 10^6$ reads, corresponding to 12 to 23% of total reads that matched to miRBase. The total cellular miRNA profiling yielded 700-850 annotated miRNAs from the four cell lines. The Ago2-IP sequencing resulted in about $28\text{-}55 \times 10^6$ reads, corresponding to 78.82-68.25% of all reads. The Ago2-IP miRNA profiling, yielded 1102 to 1372 miRNAs, annotated in miRBase. Thus, the total number of reads for known human miRNA reads, increased about 10 times, as compared to the total cellular profile, indicating that the Ago2-IP strongly enriched the miRNAs, proving the specificity of the procedure.

	Cell line	Total reads	Total reads match with miRBase	% of match reads	Detected miRNA
Total	U2932-EBV	10423487	1,815,328	17.42	851
	U2932	8752305	2,076,239	23.72	758
	SUDHL5-EBV	11470056	2,019,181	17.60	763
	SUDHL5	15322853	1,944,300	12.69	713
Ago2_IP	U2932 -EBV +	55928169	38,168,544	68.25	1372
	U2932	42384180	26,494,508	62.51	1185
	SUDHL5-EBV	34811526	27,005,099	77.58	1141
	SUDHL5	28245506	22,264,473	78.82	1102

It has been suggested that only miRNAs which represent more than 0.1% of the total reads are functional (FLORES et al., 2014; MULLOKANDOV et al., 2012). For this reason, a 0.1% cut-off was applied for further analysis in all cell lines for selection of functionally relevant miRNAs. This means that in our analysis, only a miRNA with at least an expression of 0.1% of the total reads in one of the cell line was taken into account.

At the 0.1% cut-off level, only 61 to 62 of human miRNA remained in the total cellular miRNA profile of U2932 and U2932-EBV cells; however, these corresponded to 96.4% to 94.4% of total annotated miRNA reads, respectively. In SUDHL5 and SUDHL5-EBV, 59 to 58 of human miRNA were detected in the total cellular lysate, representing

73.3% and 97.0% of detected miRNAs, respectively. At the 0.1% cut-off level in the Ago2-profile 51 to 66 of human miRNA were detected in U2932-EBV and U2932, corresponding to 94.8% to 97.0% of the total miRNAs, respectively. In SUDHL5-EBV and SUDHL5, 50 to 54 human miRNA were detected in the Ago2-IP, representing 68.6% and 97.2% of miRNA reads, respectively.

The presence of EBV miRNA was also analyzed in the total cellular and the Ago2-IP miRNA profile. In U2932-EBV cells, six EBV-miRNAs (1.3% of all reads), and in SUDHL5-EBV cells, 26 EBV-miRNAs (23.4% of total reads), remained above 0.1% cut-off level, whereas in the Ago2-IP profiling of U2932-EBV cell line, 6 EBV (1.6% of total miRNA reads) and the SUDHL5-EBV cell line, 23 EBV miRNAs (28.2% of total reads) were present above the 0.1% cut-off level (Table 5).

Table 5: MiRNA reads in “Total” and “Ago2-IP” at 0.1% cut-off.					
	Cell line	Human miRNA	EBV miRNA	% of Human miRNA	% of EBV miRNA
Total	U2932 -EBV	62	6	94.4%	1.3%
	U2932	61	-	96.4%	-
	SUDHL5-EBV	58	26	73.3%	23.4%
	SUDHL5	59	-	97.0%	
Ago2_IP	U2932-EBV	51	6	94.8%	1.6%
	U2932	57	-	97.0%	-
	SUDHL5-EBV	50	23	68.6%	28.2%
	SUDHL5	54	-	97.2%	-

3.4 Highly expressed miRNAs in U2932 and SUDHL5 and their EBV-positive counterparts

There is an inverse relation between the expression level of a miRNA and its inhibitory potential for a specific mRNA target, and a crucial role for Ago2 protein in the RISC silencing complex (LEUNG et al., 2011; LIU et al., 2016). Therefore, we analyzed the expression of the most abundant miRNAs in the total cellular and Ago2-IP miRNA profiles in each cell line, separately, at the 0.1% cut-off level. The top 20 miRNAs in the total cellular and the Ago2-IP profile are listed in descending order in Table 6 and Table 7. These miRNAs comprised about 74 to 85% of all identified miRNA reads in the four DLBCL cell lines. For instance, in the total cellular profiles, miR-92a-3p and miR-191-5p were among the most abundant miRNAs in the U2932 cell lines and miR-21-5p and miR-142-5p were, among the most highly expressed miRNA in the SUDHL5 cell lines.

Table 6 : Top 20 miRNAs in U2932 and SUDHL5 and their EBV positive counterparts in “Total” profile at 0.1% cut-off. EBV miRNAs are underlined.

3.5 Comparative analysis of up and down regulated miRNAs in EBV infected cell line to EBV negative DLBCL cell lines in total cellular and Ago2-IP

EBV encodes 44 mature miRNAs, and the EBV-infection might change the total cellular miRNA profile. Therefore it could also influence the loading of the Ago2-complex with human miRNAs. Accordingly, the fold changes of human miRNAs were analyzed and compared, between EBV-infected and their non-infected counterparts. For the sake of this comparison, we again considered only miRNAs above the 0.1% cut-off level, for functionally relevant miRNAs. The top 10 induced and reduced miRNAs, due to EBV infection in total cellular profile are shown in Table 8, and the complete lists can be found in the appendix (Tabel A5).

U293. Total				SUDHL5 Total			
miRNA	EBV +	EBV -	Ratio EBV +/-	miRNA	EBV +	EBV -	Ratio EBV +/-

In the total cellular profile of U2932-EBV, miR-4485-3p, -221-3p and -222-3p were found to be the most strongly induced, while miR-182-5p,-146-5p and -10a-5p had the highest induction in SUDHL5-EBV. In contrast, let-7c-5p and miR-27a-3p were most strongly reduced in U2932-EBV, and miR-4792 and miR142-3p had the strongest reduction in the total cellular miRNA profile in SUDHL5-EBV.

A comparison of the Ago2-IP in EBV positive versus EBV negative cells are shown in Table 9, for the top 10 induced and reduced miRNA, and the complete lists can be found in the appendix (Tabel A6). MiRNAs such as miR-15a-5p, -221-3p and- 155-5p had the strongest relative presence in the Ago2-complex of 2932-EBV, compared to U2932. MiR-363-3p,-182-5p had the strongest induction in SUDHL5-EBV, compared to SUDHL5 while miR-let-7c-5p and -27a-3p showed the strongest reduction in U2932-EBV as compared to U2932 . MiR-142-3p and -5p were the most strongly depleted from the Ago2-complex in SUDHL5-EBV compared to SUDHL5.

Table 9: Comparison of “Ago2-IP” profile in EBV-positive vs. non-infected cell lines vs. “Total” profile at 0.1% cut-off.

3.6 Differential RISC associated of human and EBV miRNAs in comparison to cellular miRNA profile

As mentioned, the Cullen group challenged the notion that the total cellular miRNA profile is a realistic functional indicator of the association of a miRNA with the RISC complex. They found a discrepancy in various miRNAs in the Ago2-IP profiling as compared to the total cellular profile (FLORES et al., 2014). Accordingly, we also analyzed the relative enrichment or depletion of human Ago-bound miRNAs, versus the total cellular miRNA profile at 0.1% cut-off for each of the four DLBCL cell lines, separately. The top 10 enriched or depleted human miRNAs in Ago2-complex are

shown in Table 10, for U2932 and its EBV positive counterpart, and in Table 11 for SUDHL5 and its EBV positive counterpart. For instance, miR-423-5p and -3p were enriched 2.5-8 fold in Ago2-IP in comparison to the total cellular miRNA profile in the four cell lines.

Table 10:List of miRNAs enriched or depleted from the “Ago2-IP”as compared to the “Total” profile in U2932-EBV and U2932 at 0.1% cut-off.							
U2932-EBV				U2932

MiR-4792, -1246 and -4485-3p in U2932-EBV and miR-1260a , -1260b and -4792 in U2932 were identified to be strongly depleted more than 69 fold in the RISC complex, as compared to the total cellular miRNA profile.

In SUDHL5-EBV, miR-486-5p, -260a, -260b,-and -4485-3p were the most strongly depleted miRNAs from Ago2-complex, whereas miR-4532, -1260a and -4792 were depleted about 78 to 3000 fold, from the Ago2-complex in SUDHL5.

Table 11: List of miRNAs enriched or depleted in the “Ago2-IP”as compared to the “Total” profile in SUDHL5–EBV and SUDHL5 at 0.1 % cut –off.

3.7 Presence of EBV miRNAs in the Ago2-containing RISC complex.

We analyzed the presence and abundance of EBV miRNAs in the total cellular fraction and the Ago2-miRNA profile in the EBV-infected cell lines. As shown in Table 12, the overall amount and the presence of virus-encoded miRNAs varied between the two cell lines. As already pointed out, the virus contributed only about 1.3% to the total amount of miRNAs in U2932-EBV, while 23.4% of the total miRNA reads were derived from the virus in SUDHL5-EBV. In U2932-EBV, EBV-miR-BART10-3p constituted only 0.43%, and BART8-5p, 0.29% of the total counts. In SUDHL5-EBV, the viral miRNAs EBV-miR-BHRF1-1, -BART10-3p and -BART8-5p contributed to 5.97%, 3.25% and 2.97% of the total miRNA reads, respectively.

In the Ago2-profiling of the U2932-EBV cell line, EBV-miR-BART8-5p, -BART11-3p and -BART6-3p were the most abundant viral miRNAs, with 0.42%, 0.33% and 0.31% abundance, respectively. In the SUDHL5-EBV, BHRF1-1, BART8-5p and BART6-3p were the most abundant EBV miRNAs in total cellular profile, with 7.02%, 4.15% and 3.14% abundance, respectively. The most abundant EBV miRNAs in total cellular profile were found to be same in the Ago2-complex, while BHRF1-1, BART10-3p and BART8-5p were the most abundant miRNA in total cellular profile in SUDHL5 (see below).

Table 12: EBV miRNAs in the “Total” and the “Ago2-IP” profile in U2932-EBV and SUDHL5-EBV.							
U2932				SUDHL5			
miRNA	Total	miRNA	Ago	miRNA	Total	miRNA	Ago2
	rel. expr. %		rel. expr. %		rel. expr. %		rel. expr. %
BART10-3p	0.4365	BART8-5p	0.42474	BHRF1-1	5.971	BHRF1-1	7.0296
BART8-5p	0.2964	BART11-3p	0.33851	BART10-3p	3.2542	BART8-5p	4.1537
BART6-3p	0.1967	BART6-3p	0.31849	BART8-5p	2.9754	BART6-3p	3.1426
BART11-3p	0.1582	BART10-3p	0.24271	BART7-5p	1.3665	BART10-3p	2.4979
BART22	0.1281	BART19-5p	0.18918	BART19-5p	1.2667	BART11-3p	1.9503
BART7-5p	0.1138	BART7-5p	0.13593	BART11-3p	1.1298	BART19-5p	1.889
				BART6-3p	1.0978	BART7-5p	1.6766

The enrichment of EBV miRNAs in the Ago2-complex, in comparison to the total cellular profile, was determined. As shown in Table 13, miR-BART11-3p and miR-BART19-5p were enriched more than 2-fold in U2932-EBV, while miR-BART10-3p was depleted from the Ago2-complex by 1.8-fold, as compared to the total cellular profile. In SUDHL5-EBV, miR-BART6-3p and miR-BART11-3p were strongly enriched, by 2.8 and 1.7 fold, respectively, while EBV-miR-BART5-5p and -BART1-3p were depleted, below the 0.1% cut-off.

Table 13: List of EBV-miRNA enriched or depleted in the “Ago2-IP” compared to “Total” profile in U2932-EBV positive and SUDHL5-EBV at 0.1 % cut-off.

3.8 Validations of sequencing results by RT-qPCR

In order to validate the NGS sequencing results, 12 miRNAs with different expression levels, either up- or down-regulated, were selected for reverse transcription quantitative PCR (RT-qPCR), based on their presence above the 0.1% cut-off level. The RT-qPCR was carried out in duplicate on independent biological replicates for both cell lines and their EBV-infected counterparts, in the total cellular RNA and the RNA isolated from the Ago2-IP.

The RT-qPCR results of 8 out of 12 selected miRNAs gave results corresponding to the NGS results of total cellular RNA from U2932-EBV, compared to U2932. As shown in Figure 8, we validated the relative upregulation of four miRNAs, including miR-10a-5p, -146a-5p, -221-3p and -363-3p and the relative downregulation of four miRNA, including let7c-5p, miR-283p, miR-423-3p and miR-92a-3p.

Figure 8:RT-qPCR validation for U2932-EBV vs. U2932 in “Total”

Black bars represent NGS data and white bars represent RT-qPCR results.

Furthermore, using RNA extracted from the Ago2-IP of U2932-EBV and U2932, the relative upregulation of miR-10a-5p, miR-146a-5p, miR-155-5p, and miR-15a-5p, miR-221-3p, miR-363-3p, mi -486-5p, miR-92a-3p and relative downregulation of let-7c and miR-28-3p were confirmed. These data are presented in Figure 9.

Figure 9:RT-qPCR validation of U2932-EBV vs. U2932 for “Ago2-IP”

Black bar represent NGS data and open bars represent RT-qPCR results.

The analogous experiments, employing RNA obtained from whole cells or the Ago2-IPs were carried out, for comparing SUDHL5-EBV vs. SUDHL5. Here, 10 out of 12 selected miRNA yielded consistent results for the sequencing of total cellular miRNA profile. As shown in Figure 10, we confirmed the relative up-regulation of five miRNAs, including miR-10a-5p, -146a-5p, -155-5p, -221-3 and -363-3p and a relative downregulation of five miRNAs, including miR-15a-5p, -28-3p, -423-3p, -423-5p and -92a-3p.

Figure 10:RT-qPCR validation for SUDHL5-EBV vs. SUDHL5 for “Total”

Black bars represent NGS data and open bars represent RT-qPCR results.

Using RNA extracted from Ago2-IP for comparing by RT-qPCR SUDHL5-EBV vs. SUDHL5, we confirmed the relative up- and downregulation of selected miRNAs as shown in Figure 11. In particular, the relative upregulation of miR-10a-5p, -146a-5p, -155-5p, -221-3p and -363-3p and the relative downregulation of miR-let-7c,-15a-5p, -28-3p, -423-3p, -423-5p, -486-5p and -92a-3p were validated.

3.9 Verification of sequencing by Northern blotting

3.9.1 Analysis of total cellular miRNAs

Northern blotting (NB) is considered the gold standard for validation of miRNA expression, as it avoids the false positive results that may arise from the enzymatic manipulation and amplifications that are necessary for biochemical reactions during the NGS or RT-qPCR procedures. Second, it unambiguously detects differences in expression in given cellular settings, like the ones analyzed in this work. For this reason, we performed NB as a powerful second validation method for some miRNAs that were found to be up- or downregulated by NGS and RT-qPCR.

The results of NB from total extracted RNA from U2932, SUDHL5 and their EBV-positive counterparts, are shown in Figures 12, 13, and 14. In comparison of U2932-EBV with U2932, we confirmed the upregulation of miR-222-3p, -551b-3p, -142-3p, -155-5p and -142-5p and the downregulation of hsa-let-7c-5p. In SUDHL5-EBV, we also verified the upregulation of miR-363, -21-5p and downregulation of miR-142-5p, compared to SUDHL5.

NGS data from Ago2-IP indicated that miR-4485-3p and 4792-5p were highly depleted from the Ago2-IP profile (Table 10 and Table 11), while miR-4485-3p and -4792-5p were above 0.1% cut-off level of total known miRNA reads, in the total cellular miRNA expression profile. MiR-4485-3p and miR-4792-5p were not present at the 0.1% cut off in U2932 and SUDHL5-EBV, respectively. We could not detect a signal either for miR-4485-3p or 4792-5p by northern blot (Figure 15).

Figure 12: Validation of NGS results by northern blotting.

Total RNA isolated from U2932, SUDHL5 and their EBV positive counterparts (20µg/lane) was assayed using probes for the indicated miRNAs. The EtBr loading control is shown beneath each blot.

Figure 13: Validation of NGS results by northern blotting.

Total RNA isolated from U2932 and SUDHL5 and their EBV positive counterparts (20µg/lane) was assayed using probes for the indicated miRNAs probes. The EtBr loading control is shown beneath each blot.

Figure 14: Validation of NGS results by northern blotting.

Total RNA isolated from U2932 and SUDHL5 and their EBV positive counterparts (20µg/lane) and human tissue from a DLBCL patient were assayed by the probes for the indicated miRNAs. The EtBr loading control is shown beneath each blot.

Figure 15: Validation of NGS results by northern blotting.

Total RNA isolated from U2932 and SUDHL5 and their EBV positive counterpart (20µg/lane) were assayed by NB using probes for miR-4485-3p and miR-4792-5p as indicated. No proper signal detected for miR-4485-3p and 4792-5p) while reprobng of the same membrane after stripping gave a detectable signal for mir101-3p. The EtBr loading control is shown beneath each blot.

3.9.2 Analysis of Ago2-IP miRNAs by northern blotting.

From our NGS results and their validation using RT-qPCR, we found that by comparing Ago2-IP in U2932-EBV versus U2932 cell lines, miR-221-3p was strongly upregulated (0.114% versus 0.045%) by 2.5-fold and hsa-let-7c-5p was strongly downregulated (0.013% vs. 0.115%) by 8-fold. We then speculated if we could detect the difference by NB, using RNA extracted from the Ago2-IP- fraction. We were able to isolate RNA from the Ago2-IP and, to a lesser extent, from the control IP. The amounts isolated were sufficient to run several Northern blots. We loaded equal amounts (200 ng) of RNA extracted from the Ago2-IP and the control-IP of U2932, as shown in Figure 16. As expected, miR-221-3p was enriched in both Ago2-IP fraction and total cellular lysate in U2932-EBV, in comparison to U2932. By stripping the membrane to remove the previous signal (miR-221-3p), and probing with hsa-let7c-5p, which was downregulated in U2932-EBV cell lines, from Ago2-IP NGS data, we observed the depletion of let-7c-5p in U2932-EBV in total cellular lysate and in the Ago2-IP. These results were in line with our NGS and RT-qPCR data for miR-221-3p and hsa-let7c-5p.

From our NGS results for SUDHL5-EBV versus SUDHL5, we found that miR363-3p (0.105 vs. 0.017) in Ago2-IP has the strongest enrichment of about 6-fold. MiR-423-5p showed the strongest enrichment in the Ago2-ip, in comparison to the total cellular profile, by more than 6- fold in SUDH-EBV (0.134 vs. 0.936) and about 8 fold (0.188 vs. 1.639), in SUDHL5. In addition, miR-423 about 1.75 fold downregulated in Ago2-IP in SUDHL5-EBV, compared to SUDHL5. By performing Ago2-IP-NB, using again 200 ng of extracted RNA from Ago2-IP fraction, we found an enrichment of miR-363-3p in the Ago2-IP of SUDHL5-EBV. After stripping and reprobing the membrane with miR423-5p, we observed depletion of mir423-5p in Ago2-IP of SUDHL5, compared to SUDHL5-EBV. These results were also in line with our NGS and RT-qPCR data.

Figure 16: Validation of Ago2-IP-Seq by northern blotting.

Total RNA isolated from U2932-EBV and U2932 total cellular and Ago2-IP cell lines. (20 μ g per lane from total cellular RNA and 200 ng per lane from Ago2-IP) were applied to 12.5% urea gel and assayed by NB using the indicated probes. First miR-221-3p probe were used and then the membrane was probed with let-7c-5p (after stripping the membrane to remove the primary signal). The EtBr loading control is shown under the blot. Due to the low amount of RNA loaded in Ago2-IP fraction (200 ng), no signals were detected in EtBr of Ago2-IPs and Control-IPs.

Figure 17: Validation of Ago2-IP-Seq by northern blotting.

Total RNA isolated from SUDHL5-EBV and SUDHL5 total cellular and Ago2-IP cell lines. (20 μ g per lane from total cellular RNA and 200 ng per lane from Ago2-IP) were applied to 12.5% urea gel and assayed by NB using the indicated probes. First miR-363-3p probe were used and then the membrane was probed with miR-423-5p (after stripping the membrane to remove the primary signal). The EtBr loading control is shown under the blot. Due to the low amount of RNA loaded in Ago2-IP fraction (200 ng), no signals were detected in EtBr of Ago2-IPs and Control-IPs.

4 Discussion

Non-Hodgkin lymphoma (NHL) is the fifth most common type of malignancy globally. Of these, diffuse large B-cell lymphoma (DLBCL) is the most common form of NHL (BRADSHAW et al., 2016; SKRABEK et al., 2013). DLBCL is a heterogeneous group of disease in regard to pathology and clinical and genetic characteristics. The heterogeneity arises due to dysregulation of different transcription factors such as B-cell lymphoma 6 (BCL-6) at different stages of B-cell development (GATTO, BRINK, 2010; IQBAL et al., 2009; IQBAL et al., 2015). DLBCL is categorized into two common types: Activated B-cell like (ABC) and Germinal Center B-cell like (GCB), based on gene expression profiling (GEP) (ALIZADEH et al., 2000). Due to difficulties in the characterization and differentiation of GCB- from ABC-DLBCL, many investigators attempt to identify a miRNA or a set of miRNAs to use as potential diagnostic differentiation biomarkers (ALIZADEH et al., 2000; IQBAL et al., 2015; JORGENSEN et al., 2015; ROSENWALD et al., 2002).

Ago2-IP, followed by miRNA sequencing, is becoming an advanced tool to determine the miRNA profile of a given tumor and to investigate functionally active miRNA, as it has been shown recently by the Cullen group that simply the level of a miRNA in the total cellular lysate is not a clear indication of its biological function but rather the loading of the Ago-complex (FLORES et al., 2014).

For this reason, this study was carried out to compare by ultra-deep sequencing the miRNAs bound to Ago2 with the overall miRNA present in two sets of DLBCL cell lines with and without EBV-conversion. The first cell line was U2932, which has a gene expression profile (GEP) similar to ABC-DLBCL (AMINI et al., 2002) and the second cell line was SUDHL5, which has a GEP similar to GCB-DLBCL. We investigated enriched or depleted miRNAs in the Ago2- associated complex as compared to their total cellular miRNA profile. We also validated our results by RT-qPCR and northern blot (NB) for a selected set of up or downregulated miRNAs that were deregulated in the total cellular RNA and in the Ago2-IP.

The total miRNA profiling of the four cell lines yielded between 713-851 different miRNAs while the number of miRNAs in the Ago2-IP yielded 1102-1372 different miRNAs. Further, the number of sequencing reads increased dramatically, by almost ten times, in the Ago2-IP fraction in the four cell lines, as compared to miRNAs detected in the total cellular profiles. In addition, the number of detected miRNAs in the Ago2-IP fraction was significantly increased, by more than 35% in all four cell lines, as compared to the total cellular miRNA profile. The increase in the number of reads and detected miRNAs in Ago2-IP fraction is a clear indication of enrichment and specificity of our Ago2-IP. In addition, we observed miRNAs expressed at low abundance that were not detectable in the total miRNAs profiles. This approach might therefore be applied as a very promising tool in the discovery of new miRNAs. Most importantly, the Ago-associated miRNAs might be considered as the potentially relevant miRNAs to serve as biomarkers for diagnosis and for the determination of potential mRNA targets.

As it had been suggested that functional miRNAs should be present above 0.1% of the total reads, a 0.1% cut-off was applied in all cell lines for the selection of functionally relevant miRNAs (FLORES et al., 2014; MULLOKANDOV et al., 2012). The application of this cut-off left only 59-62 out of more than about 713-851 miRNAs that were present overall in the four lines, but the application of this cut-off also left only between 50-57 miRNAs in the Ago2-profile. The miRNAs that were left, however, were present at different ratios in both U2932 and U2932-EBV as well as SUDHL5 and SUDHL5-EBV. The miRNAs above the 0.1% cut-off did nevertheless represent over 95% of all miRNAs in the four cell lines.

In the U2932-EBV cells, the EBV-encoded miRNAs represent 1.3% of the total and 1.6% of all Ago2-bound miRNAs. In this line, EBV was in latency I or II as only EBNA1 and LMP1 but not significant amounts of EBNA2 were detectable. Here, ebv-miR-BART10-3p with 0.43% of the total had the highest relative expression of the EBV-miRNAs, but was not among top 20 miRNA in U2932-EBV. In contrast, ebv-miR-BART8-5p accounted for 0.4% of Ago2-associated viral miRNAs. In SUDHL5-EBV, however, which has the characteristic of EBV-latency type III (high EBNA2, EBNA1,

LMP1), EBV miRNAs represented about 23.4% of total cellular profile, and an enrichment to about 28.2% of viral miRNAs was observed in the Ago2-IP profile. Here, ebv-miR-BHRF1-1, -BART-10-3p and BART8-5p were the most abundant viral miRNAs in total miRNA profile with frequencies of 5.9%, 3.2%, 2.9%, respectively. BHRF1-1 and BART8-5p with 7.0% and 4.1%, respectively, were also among the most abundant miRNAs in Ago2 profile in SUDHL5-EBV. This suggests that under type III EBV latency, for example, in EBV-associated PTLD, EBV miRNAs might functionally displace a significant amount of human cellular miRNAs from the Ago2-complex. In addition, the viral infection had dysregulated the human cellular miRNA expression. Alternatively, it might be possible that miRNAs in type III latency are more efficiently processed. The changes in the cellular miRNA profile in EBV latency type III, compared to type I, were previously reported by Flemington and coworkers (CAMERON et al., 2008a). We have also observed elevated expression of miR-21-5p, miR-27a-3p and miR-146b-5p in SUDHL5-EBV vs. SUDHL5 cells, which is consistent with their data.

The Venn diagrams shown in Figures 18 depict the miRNAs that are not present or exclusively in the Ago2-complexes in the four cell lines. We note that miRNAs miR-1260a/b were not present in the Ago2-complex in U2932, SUDHL5 and SUDHL5-EBV and were strongly depleted from Ago2 in U2932-EBV. Likewise, miR-486-5p was below the 0.1% cut-off in the Ago2-complex in U2932, U2932-EBV, SUDHL5-EBV except in SUDHL5. Surprisingly, the number of cellular miRNAs excluded from the Ago2-complex in U2932-EBV and SUDHL5-EBV did not differ significantly as we had expected that the large amount of EBV-miRNAs associated with Ago2 in SUDHL5-EBV (almost 30%) would lead to a stronger loss of cell miRNAs as compared to U2932-EBV where the viral miRNAs accounted for only 1.6% of the Ago2-bound miRNAs above the 0.1% cut-off. In SUDHL5, miRNAs miR-4485-3p, -4792, and -4532 were only present in the total profile, and miR-4485-3p was not Ago2-bound in SUDHL5-EBV. We assume that these sequences, although listed in miRBASE, are not real miRNAs but probably breakdown products of other non-coding RNAs. For instance, probing the RNA of the U2932 and SUDHL5 cell line did not yield a detectable signal for this sequence at the position where miRNAs migrate in a

Northern blot. Again, miR-1260a/b and -98-5p were not present in both cells, leaving miR-1246 to be excluded from Ago2 in SUDHL5, while miR-486-5p, 20a-5p, -210-3p, -15a-5p and -181a-3p were excluded from Ago2 in SUDHL5-EBV. Likewise, miR-4792, not present in the SUDHL5- Ago2, was also not Ago2-bound in the U2932/U2392-EBV pair. Here, miR-486-5p and miR-301a-3P were Ago2-excluded in both lines while U2932-EBV also had no significant amounts of let7b-3p, -miR-17-3p, -18a-5p, -21-3p, 193-3p, 222-3p, and miR-1246, the latter also being excluded in the SUDHL5-Ago2 complex (Figure 18). It may thus be assumed that the EBV-conversion results in a loss of some more miRNAs from the Ago2-complex and that the presence of EBV under latency III conditions might result in an overall reduction of cell miRNAs associated with the Ago2-complex. The displacement of miRNAs under type III latency is somewhat more prominent than type I latency, and the presence of the virus nevertheless changes the overall expression of certain cellular miRNAs. This question needs further attention in additional experiments beyond the scope of this thesis.

Figure 18: Venn diagrams: showing the miRNAs found exclusively either in the total RNA or the Ago2-profiling of the U2932, SUDHL5 and their EBV infected counterparts. (A) Total miRNA profile vs. Ago2-profile of U2932-EBV, (B) Total miRNA profile vs. Ago2-profile of U2932 (C) Total miRNA profile vs. Ago2-profile of SUDHL5-EBV, (D) Total miRNA profile vs. Ago2-profile of SUDHL5.

MiR-21-5p was the most abundant miRNA in the total and in the Ago2 miRNA profile of SUDHL5-EBV cells. It has been shown that EBNA2 induces miR-21 expression, due to post-transcriptional mechanisms and in EBV latency type III (CAMERON et al., 2008a; ROSATO et al., 2012). Upregulation of mir-21 has been reported in different type of cancers, such as colorectal (ASANGANI et al., 2008), sinonasal

(KOVARIKOVA et al., 2017), glioblastoma (CHAN et al., 2005) and breast cancer (IORIO et al., 2005).

Microarray or NGS assay may over- or underestimate the quantification of small RNAs, due to different designing platforms (LESHKOWITZ et al., 2013). For example, in microarray biases may arise due to primer and/or array design or in the sample preparation, differences in labeling, hybridization strength and cross-hybridization (LESHKOWITZ et al., 2013). NGS biases could be a consequence of sample preparation, such as adapter ligation, cDNA synthesis and PCR (HAFNER et al., 2011; LESHKOWITZ et al., 2013; LINSEN et al., 2009; TIAN et al., 2010).

Using microarray to compare the miRNA profiles of U2932-EBV versus U2932, we found that only 14 were miRNAs significantly down-regulated in total cellular profile of U2932-EBV while 169 human miRNAs were down-regulated in the Ago2-IP.

In the comparison of U2932-EBV vs. U2932 in total cellular profile only miR-222 was upregulated more than 2 fold in both microarray and NGS results. In the Ago2-IP of U2932-EBV vs. U2932 in Ago2-IP profile, only miR-27a, miR-339 and miR-30c were downregulated more than 2 fold in both microarray and NGS results. By relating these findings with EBV infection it could be concluded that a large number of human miRNAs were dislocated in the Ago2-IP profile. In sequencing miRNA expression is defined as a relative copy number of sequence reads for a miRNA of interest; such a quantification can be applied to analyse the enrichment or depletion of a given miRNA, whereas such a quantification cannot be applied to microarray data where quantification is based on the relative expression value. For this purpose, NGS results were used for further analysis as we could not apply our microarray results to compare the enrichment or depletion of specific miRNA in the Ago2-complex. In addition, only after sequencing it was possible to apply the aforementioned 0.1% cut-off to filter out presumably non-functional miRNAs in our analysis (MULLOKANDOV et al., 2012).

For selected miRNAs, we carried out northern blotting (NB) in addition to the confirmation of the NGS data by RT-qPCR. We could confirm the up-or down-regulation of various miRNAs by this assay which has the advantage of the absence

of biochemical manipulations during sample preparation. We could confirm not only the changes in total miRNA expression but also a few miRNAs from the Ago2-IP. As we had no loading or internal control, we choose to analyze miRNAs that were up- or down-regulated. We reasoned that if we saw up-regulation of a miRNA in a given sample, then we should conversely observe down-regulation of another miRNA in the same sample. This was indeed the case. For this reason, we re-assayed the same membrane with consecutive probes and could indeed show up- and down-regulation of miRNAs on the same membrane (Figure 16 and Figure 17) additionally confirming some of the initial sequencing data. For instance, we could confirm the dramatic enrichment of miR-363 into to Ago2-complex of SUDHL5-EBV cells.

Based on read counts, we detected miR-146a-5p was enriched in Ago2-IP and induced in EBV positive cell lines, congruent with previous reports that miR-146a-5p was induced by LMP1 (CAMERON et al., 2008b). MiR-146b-5p is up-regulated in EBV positive DLBCL lymphoma (DE ANDRADE et al., 2014). Low expression of MiR-146b-5p, a tumor suppressor, has been reported to be associated with poor prognosis, in DLBCL and gliomas cancer (LIU et al., 2015b; WU et al., 2014). In our data, the miR-146b was down-regulated in U2932-EBV (type 1 latency) as compare to U2932, while the miR-146b-5p was upregulated over two-fold in SUDHL5-EBV as compared to SUDHL5, while this miRNA was depleted over two-fold in total and Ago2-IP complex in U2932-EBV. Another tumor suppressor, miR-148a-3p/-5p was found to be down-regulated in U2932-EBV vs. U2932, while being up-regulated in SUDHL5-EBV vs. SUDHL5 (YU et al., 2016) .

Further, we found a very strong enrichment of the oncogenic miR-363-3p (SUN et al., 2013) in SUDHL5-EBV. The miR-106-363 cluster has close homology with the miR-17-92 cluster (LANDAIS et al., 2007). The miR-17-92 cluster (miR-17, miR-18a, miR-19a, miR-20a, miR-19b-1, and miR-92-1) is located in 13q31.3 (DIOSDADO et al., 2009). It has been reported that the miR-17-92 cluster undergoes amplification and overexpression in lymphoma tumors, such as DLBCL, chronic lymphocytic leukemia (CLL), Burkitt's lymphoma (BL) and mantle cell lymphoma (MCL) (DAL BO et al., 2015; DIOSDADO et al., 2009; OTA et al., 2004; TAGAWA, SETO, 2005; VOLINIA et al.,

2006). From the miR-17-92 cluster, miR-92a-3p showed the strongest expression in U2932 cells and was the fourth highly expressed miRNA in the Ago2 profile of SUDHL5 and SUDHL5-EBV.

In SUDHL5, SUDHL5-EBV and also U2932-EBV, miR-423-5p and -3p were the most strongly RISC enriched miRNAs, and still the 2nd and 4th enriched in U2932, pointing at an important role for miR-423 in DLBCL tumorigenesis. miRNA-423-5p has been shown to be down-regulated in the plasma of colorectal cancer (CRC) patients (FANG et al., 2015) . However miR-423 is up-regulated in glioblastoma and it has been shown that overexpression of miR-423-5p induces proliferation, angiogenesis, and invasion in the glioblastoma cell lines U87 and U251 cells (LI et al., 2017). MiR-inhibitor of growth family proteins 4 (*ING4*) is a direct target of 423-5p (LI et al., 2017). It has also been shown that in EBV infected cell lines, the EBNA3C protein perturbs the interaction between *p53* and *ING4/5* in EBV infected cell lines, resulting in attenuation of *p53*, apoptosis and induction of cell proliferation (SAHA et al., 2011).

We observed an almost complete loss of miR-1260a and miR1260b, in the Ago2-IP profile, in all cell lines used in this study. MiR-1260a and miR1260b has an oncogenic potential (XU et al., 2015) . MiR-1260a and miR1260b have been shown to be part of transfer RNAs (tRNAs) group3 (tRF-3). tRF-3 are generated by Dicer and the RNase Z nuclease from 3' ends of tRNA (LEE et al., 2009; VENKATESH et al., 2016). It was shown that tRF-3s family members are associated with AGO1, 3, and 4, in HEK293 cells, but not with Ago2. This might explain the failure to detect 1260a/b in the Ago2-IP (KUMAR et al., 2014) .

MiR-486-5p is downregulated in lung cancer (WANG et al., 2014). In our experiments, miR-486-5p was above 0.1% cut-off level of total known miRNA reads in total cellular profile and upregulated in U2932-EBV and SUDHL5-EBV as compare to the uninfected cells. Intriguingly miR-486-5p was strongly lost in Ago2-complex with less than 0.03% abundance in all cell lines except SUDHL5, and downregulated in SUDHL-EBV and U2932-EBV compared to uninfected counterparts. We infer from these results that the Ago2-IP profile gives a better picture about the tumor suppressor

activity of miR-486-5p. As already pointed out above, we have noticed the absence of miR-4792, miR-4485-3p and miR-4532 in the Ago2-complexes when compared to the total cellular miRNA profiles. No proper signal was detected by using NB. These miRNAs might be part of transfer RNAs, associated with other types of Ago protein, or could be degraded tRNA products and are therefore most likely not bona fide miRNAs. The function of the aforementioned potential miRNAs should be investigated in more detail. Mir-221-3p and miR-155-5p were induced in U2932-EBV as compared to U2932. These results were consistent with those of Lawrie and co-workers (LAWRIE et al., 2007). However, miR-221-3p was not detected in neither of SUDHL5-EBV or SUDHL5 cell line.

MiR-142-3p was found to be downregulated in the Ago2 profile of U2932-EBV and SUDHL5-EBV cells. In contrast, in the total cellular profile of U2932-EBV cell line, miR-142-3p was upregulated. Overall, the depletion of miR-142 in the Ago2 profile compared to the total cellular profile and down regulation of miR-142 in EBV-infected cells was a clear indication of miR-142 being a tumor suppressor in DLBCL. It has been shown that miR-142 is downregulated in many types of cancers and that low levels of mir-142 predict a poor outcome. In our group, we have shown that 20% of DLBCLs harbor mutations in miR-142 and that the mutations in the seed sequence confer loss of activity (KWANHIAN et al., 2012). Here, we propose that in addition to point mutations, the depletion of miR142 in the Ago2 complex supports the notion that loss of function or loss of Ago-bound miR-142 plays a role in DLBCL.

Taken together, we conclude that the human miRNA expression profile in the total cellular fraction is not always a real indicator of miRNA function and therefore functional activity. EBV, by encoding miRNAs, is displacing human miRNAs from the Ago complex and changes the balance of human miRNAs in the Ago complex. This change is dependent on the type of EBV latency or the origin of lymphoma, in our study ABC-DLBCL vs. GCB-DLBCL

5 Outlook

One question that arises from our data and the results from Cullen and co-workers is how the cell decides to sequester miRNAs into (a) functionally silent Ago-complex(es) or to enrich miRNAs of low abundance into active RISC complexes; in EBV transformed cells, the process of functional inactivation might be brought about by loading additional, virus-encoded miRNAs into the Ago-complexes. Conversely, the infected cell might sequester viral miRNAs that are deleterious for the cells into non-functional Ago-complexes thus activating otherwise non-functional miRNAs. We have found that ebv-miR-BART6 is highly present in the Ago2-complex of SUDHL5-EBV cells; this miRNA is known to target Dicer, an important enzyme in miRNA metabolism and function. It might be possible that reduced amounts of Dicer serve to inactivate cell miRNAs, for instance those that are necessary to indicate the innate immune response to the viral infection.

As miRNAs are more functional in the Ago complex than in the total cellular lysate, performing Ago2-IP followed by sequencing will give a better evaluation and understanding of highly functional miRNAs or, conversely, their loss of activity. This approach may improve our understanding the contribution of miRNAs in particular diseases or in developmental processes.

Further, the enrichment of miRNAs by the Ago-precipitation will be a promising tool in the near future for (1) the discovery of new miRNA due to the high number of reads generated by this procedure; (2) for the design and choice of antagomirs (short oligonucleotides complementary to miRNAs), based on highly abundant miRNA in the Ago2-complex; (3) choosing miRNAs as biomarkers to differentiate ABC-DLBCL from GCB-DLBCL, using the Ago-bound miRNA profiles.

8 Abbreviations

Ago	Argonaute Protein
Ago2-RIP-seq	Ago2-based RNA immunoprecipitation (RIP)
APS	Ammonium persulfate
Bcl-2	B-cell CLL/lymphoma 2
BHRF1	Bam HI fragment H rightward open reading frame 1
DNA	Deoxyribonucleic acid
dNTP	Desoxyribonucleosidtriphosphate
EDTA	Ethylenediaminetetraacetic acid
FCS	Fetal Calf Serum
CACNG8	Calcium Voltage-Gated Channel Auxiliary Subunit Gamma 8
H ₂ O ₂	Hydrogen Peroxide
HCL	Hydrogen Chloride
KCl	Potassium Chloride
kDa	Kilo Dalton
M	Molar
mA	Milliampere
mg	Milligram
MgCl ₂	Magnesium Chloride
min	Minute
ml	Milliliter
mRNA	Messenger RNA
Na ₂ HPO ₄	Sodium Hydrogen Phosphate
NaOH	Sodium Hydroxide
NTP	Nucleoside Triphosphate
PBS	Phosphate Buffered Saline
RISC	RNA Induced Silencing Complex
RNA	Ribonucleic Acid
RPM	Rotations Per Minute

RPMI-1640	Roswell Park Memorial Institute-1640
SDS	Sodium Dodecyl Sulphate
SDS-PAGE	Sodium Dodecyl Sulphate- Polyacrylamide Gel Electrophoresis
sec	Second
SSC	Saline Sodium Citrate
TAE	Tris base, acetic acid, EDTA
TBE	Tris base, boric acid, EDTA
TE	Tris base, EDTA
TEMED	N,N,N',N'-tetramethylethane-1,2-diamine
TNRC6A	Trinucleotide repeat containing 6 A
V	Volt
W	Watt
μL	Microliter
μg	Microgram

10 List of tables

Table 1: Different stages of EBV latency.	20
Table 2: Summary of miRNAs detected by microarray, in “Total” and “Ago2-IP” profile in U2932-EBV and U2932.	47
Table 3: Top 10 up regulated miRNAs and top 14 down regulated miRNAs in U2932-EBV vs. U2932 measured by microarray.	48
Table 4: Overview of sequencing reads in “Total” and “Ago2-IP” obtained from U2932 and SUDHL5 and their EBV positive counterparts.	51
Table 5: MiRNA reads in “Total” and “Ago2-IP” at 0.1% cut-off.	52
Table 6 : Top 20 miRNAs in U2932 and SUDHL5 and their EBV positive counterparts.....	54
Table 7: Top 20 miRNAs in U2932 and SUDHL5 and their EBV positive counterparts in “Ago2-IP” profile at 0.1% cut-off. EBV miRNAs are underlined.....	55
Table 8: Comparison of miRNA profiles in EBV+ vs. EBV- in “Total” profile in	56
Table 9: Comparison of “Ago2-IP”profile in EBV-positive vs. non-infected	58
Table 10:List of miRNAs enriched or depleted from the “Ago2-IP”as compared.....	59
Table 11:List of miRNAs enriched or depleted in the “Ago2-IP”as compared to the “Total” profile in SUDHL5–EBV and SUDHL5 at 0.1 % cut –off.....	60
Table 12:EBV miRNAs in the “Total” and the “Ago2-IP” profile in U2932-EBV	61
Table 13: List of EBV-miRNA enriched or depleted in the “Ago2-IP”compared to “Total” profile in U2932-EBV positive and SUDHL5-EBV at 0.1 % cut-off.....	62

11 Acknowledgements

If words are reflecting as symbols of acknowledgement, then words play important role of thanks to exhibit the deeply embedded feelings of appreciation.

First and foremost, I would like to express my sincere gratitude to Prof. Dr. Eckart Meese and Prof. Dr. Friedrich Grässer for their guidance, inspirations, scientific discussions and thought-provoking conversations, which was always there, when I need it.

I would like to thank our collaborators Prof. Elisabeth Kremmer, LMU München, Prof. Pankaj Trivedi, La Sapienza University, Prof. Dr. Andreas Keller (Clinical Bioinformatics, University of Saarland) and his team.

I would like to thank Prof. Dr. med. Sigrun Smola for allowing me to use the facilities at the department of Virology, University of Saarland.

My profound gratitude is sincerely expressed to Dr. Nicole Ludwig, for helping me throughout the projects with experiment, valuable advice and critical thoughtful suggestions.

I would like to thank Jennifer Menegatti, Dr. Martin Hart, Dr. Julia Stefanie Alles, Dr. Masood Abu-Halima, Tobias Fehlmann and all of my lab members who helped me during various stages of my doctoral study and providing a friendly environment in the lab.

I am grateful to Ruth Nord for her excellent technical support and also, I would like to thank all the member of the Institute of Human Genetics & Virology, as well as diagnostic staff members.

I would like to extend my gratitude to my friends Dr. Shahin Khoshkish, Dr. Mayur Harish Dembla, Dagmar Pogodski, Dr. Antonio Yarzagaray for their encouragement and sharing good moments during my stay in Germany.

Last but not the least, I would like to thank my parents for their blessings, emotional supports, care and encouragement without whom, I could not reach at this step in my life.

Contributions

Collaborations and interdisciplinary team work are prerequisite to Investigate scientific questions. I would like to acknowledge the following persons how contributed at various stages of experimentation and in obtaining results for my PhD Project:

SUDHL5 and SUDHL5-EBV, generated by Dr. Eleni Anastasiadou, were obtained from Prof. Pankaj Trivedi, University of Rome. Dr.Nicole Ludwig performed and help throughout the project with NGS, Microarray and RT-qPCR experiment and analyzing data.Tobias Fehlmann, M.A, analyzed the NGS and microarray data. Ms. Jennifer Menegatt (Dipl.-Biol.) helped at different steps of Northern blotting. DLBCL tissue from patients samples were obtained from the department of Pathology (PD Dr. Yoo-Jin Kim), Saarland University Medical School, Dr.Julia Stefanie Alles performed RNA extraction from DLBCL tissue. Mrs. Ruth Nord maintained all the cell lines.
