## ABSTRACT

The sequential 1,4-elimination reaction of ( $E$ )-4-alkoxy-2-butenyl benzoates and [1,2]-Wittig rearrangement gave $(2 Z, 4 E)-2,4$-pentadien-1-ols stereoselectively. Z-Selective formation of intermediary vinyl ethers, whose stereochemistry was well elucidated by the "syn-effect," was achieved by treatment of the 2-butenyl benzoates
with KOH in the presence of Pd catalyst. The subsequent [1,2]-Wittg rearrangement by use of $n$-BuLi proceeded with retention of the stereochemistry of the intermediary vinyl ethers.

## INTRODUCTION

Stereoselective synthesis of carbon-carbon double bonds as ubiquitous and versatile two-carbon units is among the most important and challenging tasks in organic chemistry. ${ }^{1}$ Consequently, a large number of synthetic methodologies have been reported, e.g., 1) Wittig reaction, which utilizes the characteristics of phosphorus, ${ }^{2}$ 2) Peterson reaction, which utilizes silicon, ${ }^{3}$ 3) Julia olefination, which utilizes sulfones, ${ }^{4,5}$ 4) reduction or carbometalation of alkynes, which takes advantage of organometallic reagents, ${ }^{6}$ and 5) olefin metathesis, which is realized by the use of Grubbs catalysts. ${ }^{7}$ However, these reactions depend on new $\mathrm{C}-\mathrm{C}$ bond formation or reductive olefin formation from alkynes. On the other hand, while the elimination reaction is also a powerful method for the preparation of olefins, the stereochemistry of the products generally depends on the reaction pathway, i.e., E2 anti-elimination, syn-elimination, or

E1 elimination. Therefore, few methods have been reported for stereoselective synthesis of olefins using simple elimination reactions. ${ }^{8}$

In our laboratory, stereoselective formation of sterically unfavorable ( $Z$ )-olefins was investigated with various types of elimination and isomerization reactions by treatment with a base. ${ }^{9}$ We proposed that $Z$-selectivity was achieved by the "syn-effect," namely a stereoelectronic effect owing to $\sigma_{\mathrm{C}-\mathrm{H}} \rightarrow \pi^{*}{ }_{\mathrm{C}=\mathrm{C}}$ interaction as depicted in Scheme 1 , in which the transition state of the 1,4 -elimination of an allylic sulfone is depicted. ${ }^{9 \mathrm{c}}$ Furthermore, it was found that $Z$-selectivity based on the "syn-effect" was enhanced when the $\delta$-substituent ( $\mathrm{R}^{1}$ in Scheme 1) was an electron-withdrawing alkoxy or halogen group.

Scheme 1. Concept of the "Syn-effect": $\sigma \rightarrow \pi^{*}$ Interaction in the Elimination Reaction of Allylic Sulfones

This methodology could then be applied to a stereoselective synthesis of ( $Z$ )-olefins in combination with $\mathrm{C}-\mathrm{C}$ bond formation. We have reported a sequential 1,4-elimination reaction of $\delta$-benzyloxy-substituted allylic sulfones followed by [1,2]-Wittig rearrangement ${ }^{10}$ to give (Z)-dienyl alcohols (2,4-pentadien-1-ols), which are useful synthetic intermediates due to the presence of both an allylic alcohol moiety and a diene moiety (Scheme 2a). ${ }^{11}$ However, the reaction was limited to only $\alpha, \alpha$-disubstituted allylic sulfones. When an $\alpha$-monosubstituted allylic sulfone was subjected to the reaction, the elimination of the benzyloxy group proceeded preferentially via deprotonation of the more acidic $\alpha$-proton (Scheme 2b). ${ }^{12}$ In this situation, the stereocontrolled preparation of (2Z)-5-monosubstituted-2,4-pentadien-1-ols still remained to be solved. Previously, we found that $(1 Z, 3 E)$-1,3-dienes were produced stereoselectively in the Pd-catalyzed elimination reaction of acyclic $(E)$-allylic acetates with a base. ${ }^{9 \mathrm{~g}}$ We anticipated this protocol would be applicable to the sequential 1,4-elimination reaction and [1,2]-Wittig rearrangement. Herein we describe the sequential reaction of stereoselective 1,4-elimination of (E)-4-alkoxy-2-butenyl benzoates via the $\pi$-allylic palladium
complex and subsequent [1,2]-Wittig rearrangement to afford (2Z, $4 E)$-5-monosubstituted-2,4-pentadien-1-ols (Scheme 2c).

## RESULTS AND DISCUSSION

We chose (E)-4-benzyloxy-1-phenyl-2-butenyl benzoate (1a) as a model substrate for the optimization of the reaction conditions. ${ }^{13,14}$ Under our previously reported conditions for allylic acetates using DBU, the Pd-catalyzed [1,4]-elimination reaction of 1a did not proceed reproducibly. Deactivation of the $\operatorname{Pd}(0)$ complex by molecular oxygen contamination was suspected as the cause. In order to prevent this deactivation,
degassed THF was used as the solvent, and the 1,4-elimination reaction was found to proceed reproducibly. After the 1,4 -elimination by treatment with $\mathrm{DBU},{ }^{15}$ an excess amount of $n-\mathrm{BuLi}$ was added to the reaction mixture to give the desired $(2 Z, 4 E)$-dienyl alcohol 2a in good yield with high Z-selectivity at the C2-C3 double bond (Table 1, Entry 1 ). ${ }^{16}$ However, a large excess (12 equiv) of $n-\mathrm{BuLi}$ was required to complete the [1,2]-Wittig rearrangement. ${ }^{17}$ The search for a base that did not react with $n-\mathrm{BuLi}$ revealed that NaOt - Bu could reduce the amount of $n$ - BuLi to 7 equiv for the [1,2]-Wittig rearrangement (Entry 2). However, the desired product 2a was not obtained with NaOt - Bu or KOt -Bu purified by sublimation (Entries 3 and 4). We supposed the actual base might be NaOH or KOH , which was generated by partial hydrolysis of NaOt - Bu or KOt - Bu . Therefore, we employed NaOH and KOH as bases for the initial elimination. To our delight, elimination proceeded ${ }^{18}$ reproducibly and further treatment with $n-\mathrm{BuLi}$ (6 equiv) gave 2a in good yield with excellent $Z$-selectivity at the $\mathrm{C} 2-\mathrm{C} 3$ double bond (Entries 5 and 6).

Table 1. Optimization of Reaction Conditions

${ }^{a}$ The ratios were determined by $400 \mathrm{MHz}{ }^{1} \mathrm{H}$ NMR spectra. Stereochemistries at $\mathrm{C} 4=\mathrm{C} 5$ were $E$.
${ }^{b}$ Sublimed $\mathrm{NaO} t$-Bu or $\mathrm{KO} t$ - Bu was used.
${ }^{c}$ MS4A was added after elimination reaction.

Under the optimized conditions, the sequential 1,4-elimination reaction and [1,2]-Wittig rearrangement of various substrates were performed (Table 2). Benzyl type ethers 1b-1d with $o-, m$-, and $p$-methyl groups produced the corresponding
(2Z,4E)-dienyl alcohols 2b-2d (Entries 2-4). When 2-butenyl benzoates 1e and 1f, bearing electron-donating or electron-withdrawing groups on the aromatic ring were employed, the desired products were also obtained with excellent Z-selectivities (Entries 5 and 6). 4-(2-Naphthylmethyloxy)butenyl benzoate $\mathbf{1 g}$ was also converted into the corresponding (2Z,4E)-dienyl alcohol 2g (Entry 7). Next, we examined the generality of the sequential reaction for ( $E$ )-2-butenyl benzoates bearing various substituents at the $\alpha$-position of the butenyl group. The desired products $\mathbf{2 h} \mathbf{-} \mathbf{2} \mathbf{j}$ were obtained in good yields with excellent $Z$-selectivities from 2-butenyl benzoates $\mathbf{1 h} \mathbf{-} \mathbf{j}$ bearing an aryl or $t$-Bu substituent on the $\alpha$-carbon (Entries $8-10$ ). However, in the case of a benzoate $\mathbf{1 k}$ with an $i$ - Pr group at the $\alpha$-position of the butenyl group, dienyl alcohol $\mathbf{2 k}$ was obtained in low yield, while excellent $Z$-selectivity was retained. In this case, by-product $\mathbf{3}$, derived from deprotonation of not $\mathrm{H} \delta$ but $\mathrm{H}_{\beta}$, followed by [1,2]-Wittig rearrangement, was obtained (Scheme 3). ${ }^{19}$

## Scheme 3. Generation of By-product 3 in the Reaction of 2-Butenyl Benzoate 1 k

 Bearing an Isopropyl Substituent at the $\alpha$-Position

In conclusion, we achieved a stereoselective synthesis of $(2 Z, 4 E)$-2,4-pentadien-1-ols via sequential 1,4 -elimination reaction and [1,2]-Wittig rearrangement starting from (E)-4-alkoxy-2-butenyl benzoates. The present method would be applicable in synthetic chemistry, because the stereochemistry can be predicted correctly by universal stereoelectronic effects. ${ }^{20}$ Development of other $Z$-selective reactions based on this strategy is currently underway in our laboratory.

## Experimental Section

General Method. ${ }^{1} \mathrm{H}$ NMR spectra were recorded on a 400 MHz NMR spectrometer. Chemical shifts $\delta$ are reported in ppm using TMS as an internal standard. Data are reported as follows: chemical shift, multiplicity ( $\mathrm{s}=\operatorname{singlet}, \mathrm{d}=$ doublet, $\mathrm{t}=$ triplet, $\mathrm{q}=$ quartet, $\mathrm{m}=$ multiplet $)$, coupling constant $(J)$ and integration. ${ }^{13} \mathrm{C}$ NMR spectra were recorded on a 100 MHz NMR spectrometer. The chemical shifts are reported relative to $\mathrm{CDCl}_{3}(\delta=77.0 \mathrm{ppm})$. The wavenumbers of maximum absorption peaks in IR spectra are presented in $\mathrm{cm}^{-1}$. HRMS (EI positive, ESI-TOF) spectra were measured with quadrupole and TOF mass spectrometers. All of the melting points were measured with a micro melting point apparatus. THF was freshly distilled from sodium diphenylketyl. THF used for 1,4-elimination was degassed by three freeze-pump-thaw cycles prior to use. DMF was distilled and stored over drying agents.
(E)-4-Alkoxy-2-butenyl benzoates $\mathbf{1}$ were prepared from the corresponding propargyl ethers and aldehydes according to the following scheme.

## Representative Procedure for Preparation of 4-Alkoxy-2-butyn-1-ol 4a:

To a solution of benzyl propargyl ether ( $4.00 \mathrm{~g}, 27.4 \mathrm{mmol}$ ) in THF ( 45 mL ), $n-\mathrm{BuLi}$ ( 16.9 mL of 1.62 M solution in hexane, 27.4 mmol ) was added dropwise at $-78^{\circ} \mathrm{C}$.

After stirring for 20 min , benzaldehyde ( $3.19 \mathrm{~g}, 30.1 \mathrm{mmol}$ ) was added and the resulted solution was stirred for 30 min at $-78{ }^{\circ} \mathrm{C}$, warmed to rt , and stirred for $3 \mathrm{~h} .{ }^{21}$ The reaction mixture was quenched with a sat. aq solution of $\mathrm{NH}_{4} \mathrm{Cl}$. After evaporating the solvent, the aqueous layer was separated and extracted with $\mathrm{Et}_{2} \mathrm{O}$. The combined organic extracts were washed with $\mathrm{H}_{2} \mathrm{O}$, brine, and dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$. The crude product was purified by silica gel column chromatography (hexane/AcOEt $=5 / 1$ ) to give $\mathbf{4 a}(6.01 \mathrm{~g}, 87 \%)$ as an oil.

In a similar manner, 4-alkoxy-2-butyn-1-ols $\mathbf{4 b} \mathbf{- 4} \mathbf{k}$ were prepared from the
corresponding propargyl ethers.

## Representative Procedure for Preparation of ( $\boldsymbol{E}$ )-4-Alkoxy-2-butenyl Benzoate 1a:

To a solution of compound $\mathbf{4 a}(2.52 \mathrm{~g}, 10 \mathrm{mmol})$ in THF ( 20 mL ), Red-Al ( 5.6 mL of 3.6 M solution in toluene, 20 mmol ) was added dropwise at $-40{ }^{\circ} \mathrm{C}$. The reaction mixture was warmed to room temperature and stirred for 3 h . The reaction mixture was quenched with a satd. aq solution of $\mathrm{Na}_{2} \mathrm{SO}_{4}$. After insoluble substrate was filtered off through celite, the solvent was evaporated. The residue was passed through silica gel short column (hexane/AcOEt $=2 / 1$ ) to afford the almost pure $(E)$-2-buten-1-ol $\mathbf{5 a}^{23}$
$(2.53 \mathrm{~g})$. This material was used for the conversion to the corresponding benzoate $\mathbf{1 a}$ without further purification. To a solution of the obtained $\mathbf{5 a}(2.53 \mathrm{~g})$ in DMF ( 40 mL ) were added $\mathrm{Et}_{3} \mathrm{~N}(2.02 \mathrm{~g}, 20 \mathrm{mmol})$, benzoyl chloride ( $1.40 \mathrm{~g}, 10 \mathrm{mmol}$ ), and DMAP ( $610 \mathrm{mg}, 5 \mathrm{mmol}$ ) at rt and the resulted solution was stirred overnight. The reaction mixture was quenched with a sat. aq solution of $\mathrm{NH}_{4} \mathrm{Cl}$. The aqueous layer was separated and extracted with AcOEt. The combined organic extracts were washed with $\mathrm{H}_{2} \mathrm{O}$, brine, and dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$. The crude product was purified by silica gel column chromatography (hexane/ $\mathrm{AcOEt}=15 / 1$ ) to give $\mathbf{1 a}(2.51 \mathrm{~g}, 70 \%$ for 2 steps $)$ as an oil.

In similar manner, $(E)$-4-alkoxy-2-butenyl benzoates $\mathbf{1 b} \mathbf{-} \mathbf{1 k}$ were prepared from the corresponding 4-alkoxy-2-butyn-1-ols $\mathbf{4 b} \mathbf{4} \mathbf{k}$.

## Representative Procedure for Sequential 1,4-Elimination Reaction and [1,2]-Wittig

Rearrangement of (E)-2-Butenyl Benzoate 1a (Table 2, Entry 1). To a mixture of powdered $\mathrm{KOH}(21 \mathrm{mg}, 1.05 \mathrm{mmol})$ and $\left[\mathrm{Pd}(\mathrm{dppe})_{2}\right](16 \mathrm{mg}, 0.018 \mathrm{mmol})$ was added compound 1a (125 mg, 0.35 mmol ) in THF ( 12 mL ) dropwise at room temperature and the reaction mixture was stirred for 18 h . After MS4A was added and the resulting mixture was stirred for 30 min , the mixture was cooled to $0^{\circ} \mathrm{C}$ and $n-\operatorname{BuLi}(1.27 \mathrm{~mL}$ of 1.62 M solution in hexane, 2.1 mmol ) was added. After 5 min , the reaction mixture was quenched with a sat. aq solution of $\mathrm{NH}_{4} \mathrm{Cl}$. The aqueous layer was separated and extracted with $\mathrm{Et}_{2} \mathrm{O}$. The combined organic extracts were washed with $\mathrm{H}_{2} \mathrm{O}$, brine, and dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$. The crude product was purified by silica gel column chromatography (hexane/AcOEt $=10 / 1$ with $1 \% \mathrm{Et}_{3} \mathrm{~N}$ ) to give 2a $(56 \mathrm{mg}, 68 \%, \mathrm{Z} / E=$ $>20 / 1$ ) as an oil.

In a similar manner, $(2 Z, 4 E)-2,4$-pentadien-1-ols $\mathbf{2 b} \mathbf{- 2} \mathbf{k}$ were obtained from $\mathbf{1 b} \mathbf{- 1 k}$.
