(Received October 30, 1984)

Abstract Pinkish epidote was found from Nakatatsu Mine, Fukui Prefecture, Japan, and its mineralogical data and crystal structure are described.

The average chemical composition is

and cell dimensions are $a=8.879(2)$, $b=5.6083(3)$, $c=10.1483(10)$ Å, and $\beta=115.42(4)^\circ$. Least-squares refinement of the structure using X-ray intensity data from a single crystal converged to an R -value of 6.42%, and shows that Fe and Mn are located over $M(3)$ sites and most Sr atoms replace Ca atoms at $A(2)$ sites. Atomic distances are 1.906, 1.883 and 1.812 Å for $M(1)-O$, $M(2)-O$ and $M(3)-O$, respectively, and 2.531 and 2.585 Å for $A(1)-O$ and $A(2)-O$, respectively.

Introduction

Al- Fe^{3+} and Sr $^{2+}$ -bearing epidotes are known in several metamorphic rocks, such as metagreywacke-quartzofeldspathic schist (Grapes and Watanabe, 1984). These epidotes have been described mainly for petrological aspects. The crystal structures of epidote minerals have been studied by many authors: e. g. Ito(1950), Dollase(1968, 1969 and 1971) and Gabe et al. (1973). However, Mn and Sr locations have not been well established.

Pinkish epidote, which contains Fe, Mn and small amount of Sr, was found from Nakatatsu Mine, Fukui Prefecture, Japan. Chemical composition, mineralogical data and crystal structure of this material are reported.

Experimental

Specimen

The sample was found in debris from Hitokata deposit of Nakatatsu Mine. Optical

* Present address: Department of Geology and Mineralogy, Faculty of Science, Kyoto University, Oiwake-cho Kitashirakawa Sakyo-ku, Kyoto 606

microscopic observation shows that the rock consists of 60% epidote, 20% quartz, 10% calcite and 10% opaque minerals; quartz appears idiomorphic or hypautomorphic, and calcite allotriomorphic. On the surface of the rock, lawmontite is also observed. Most of the pinkish epidote crystals are columnar or acicular elongating along b , and attain up to several mm in length. The optical microscopic photographs of the thin section are shown in plate 1. Optical axial angles measured are $2V(+)=85-95^\circ$.

Chemical composition

Chemical analyses were carried out using an electron microprobe analyzer, model HITACHI XMA-5A. In these analyses, small amount of Sr was detected. Chemical compositions and numbers of cations were calculated based on 12 oxygen atoms per formula unit, assuming perfect stoichiometry for the relative cation proportions (Table 1). The chemical formula averaged over five points in one grain is

X-ray studies

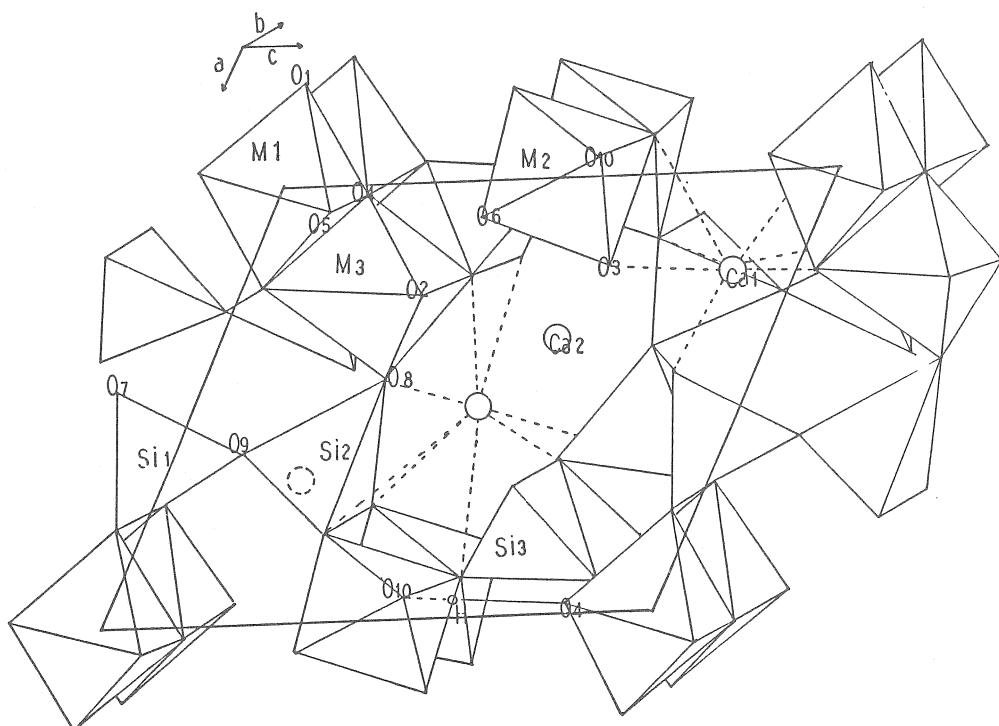

Weissenberg and precession photographs indicate that Laue group is $2/m$ and reflections $0k0$ are systematically absent if k is odd. Possible space group is thus $P2_1/m$ or $P2_1$.

A specimen, $0.07 \times 0.06 \times 0.05$ mm³ in size, was selected for intensity measurements on a Philips PW 1100 single crystal diffractometer. Cell constants were determined using 25 reflections. Crystal data and information for the structure analysis are given in Table 2. Intensities of 2247 reflections in the range of 2θ from 6 to 70° were measured with graphite monochromatized Mo K α radiation ($\lambda=0.71069$ Å) and the $\theta/2\theta$ scan mode. Structure factors of 1444 reflections, magnitude of which exceeds corresponding 3σ (F_0), were used in the following calculations.

Refinement was carried out using the least-squares program ORXFLS4 (Busing et al. 1962 and Johnson, 1969). Scattering factors for neutral atoms (*International Tables for X-ray Crystallography*, vol. IV, 1974) were used throughout this study. The space group $P2_1/m$ was assumed and initial positional parameters were taken from those by Dollase (1971). R -values with isotropic temperature factors is 6.72%. The occupancy of the M sites and the A sites were also refined (Fig. 1). First of all, the multiplicity of the M sites was refined without chemical constraints, using only the Al atomic form factor. This result (Table 4) suggests that the $M(1)$ and $M(2)$ sites are occupied only by Al, but the $M(3)$ by Al and partly heavier cations, Fe and Mn in this case. In the following calculations, the

The numbers in parentheses represent estimated standard deviations.

$$\text{Anisotropic temperature factors : } \exp \left[- \sum_{i=1}^3 \sum_{j=1}^3 h_i h_j B_{ij} \right]$$

atoms per formula unit. The final R -value is 6.42% and the parameter shifts are less than one quarter of the corresponding standard deviations. The positional and thermal parameters are listed in Table 3a and b. The structure factors are given in Appendix.

Discussion

Table 4 shows the refined site occupancies for the M and A sites. Sr is mostly distributed over the $A(2)$ sites. The chemical formula is thus calculated as $(\text{Ca}_{0.998} \text{Sr}_{0.002}) (\text{Ca}_{0.962} \text{Sr}_{0.038}) \text{Al}_{1.00} \text{Al}_{1.00} (\text{Al}_{0.603} \text{Fe}_{0.376} \text{Mn}_{0.021}) \text{Si}_3\text{O}_{13}\text{H}$ based on 12 O and 1 OH.

Tables 5 and 6 show the comparison of A -O and M -O distances with those of other epidote minerals. The chemical formula of other epidote minerals are listed in the bottom of Table 5. Mean M -O distances and their ratio to clinzozoisite are also shown in Table 6. The volume of the $A(2)$ sites of the present specimen and piemontite (Dollase, 1969) is larger than that of other epidotes where the $A(2)$ sites are occupied only by Ca. Thus the $A(2)$ site is considered to be enlarged by including large cations as Sr. Clinozoiste (Dollase, 1968) has chemical composition close to Al end-member of Al-Fe-Mn epidotes. The substitution of Fe and Mn might occur more easily in the $M(3)$ site, and therefore, the $M(3)$ -O distances become larger in proportion to the amount of Fe and/or Mn contents.

Acknowledgements

The authors are grateful to Messrs. Y. Fukabori, Y. Nishikawa and M. Machida and other members of Nakatatsu Mine for collection of the sample. We also thank Prof. S. Sugiura for encouragement and Prof. M. Yamasaki for critical reading of the manuscript. K. M. wishes to thank Mr. A. Yoshiasa, for practical guidance in experiments.
