Abstract — A new method for the synthesis of 1,4,5,6-tetrahydro-2H-indol-2-ones by means of 5-endo-trigonal cyclization of α -thiocarbocations generated from sulfoxide (12) and α -chlorosulfide (17) is described. The sulfoxide (12), upon heating with TsOH, gave 14, which eliminated benzenethiol to give tetrahydroindolone (15). By contrast, the chlorosulfide (17), upon treatment with TiCl₄, gave the desulfurized tetrahydroindolone (18). The mechanism for the formation of 18 is also discussed.

1,4,5,6-Tetrahydro-2*H*-indol-2-ones are useful intermediates for the synthesis of several types of *Amaryllidaceae* alkaloids. For examples, the *N*-(arylmethyl) derivatives (1: n = 1) having a bromine or iodine atom on the *ortho* position of the aromatic ring, when subjected to the Heck reaction conditions or to the Bu₃SnH-mediated radical cyclization conditions, give the lycorine skeletons (2), ¹ and the *N*-(2-arylethyl) congeners (1: n = 2) having electron-donating 3,4-dimethoxy groups on the aromatic ring, when treated with organic acids, provide the erythrinan skeletons (3). ^{1a}, ² Herein we report a new entry to 1,4,5,6-tetrahydro-2*H*-indol-2-ones using a 5-endo-trigonal cyclization of α -thiocarbocations³ as a key step.

[†] This paper is dedicated to the memory of Professor Emeritus Shun-ichi Yamada (Univeristy of Tokyo).

Our approach to the synthesis of tetrahydroindolones is outlined in the following Scheme. The key step is the 5-endo-trigonal cyclization of the α -thiocarbocations (4) which provides the acyliminium ion intermediates (5). This step is then followed by an elimination of benzenethiol to give 1,4,5,6-tetrahydro-3-methylthio-2H-indol-2-ones (6). The α -thiocarbocations (4) can be easily derived from the corresponding sulfoxides or α -chlorosulfides.

We initiated our investigation by examining the cyclization of the sulfoxide (12) under the Pummerer rearrangement conditions. The synthesis of 12 was begun by condensation of 2-(phenylthio)-cyclohexanone (7) with o-bromobenzylamine (8) followed by N-acylation of the resulting imine (9) with bromoacetyl bromide to give the bromoacetamide (10) in 70% yield (based on 7). Treatment of 10 with sodium methylmercaptide gave, in 80% yield, the sulfide (11), which was oxidized by slow addition of m-CPBA to give the sulfoxide (12) in 60% yield along with the disulfoxide (13) (21% yield).

Heating the sulfoxide (12) in boiling 1,2-dichloroethane in the presence of a stoichiometric amount of TsOH for 5 min gave the hexahydroindolone (14) and the tetrahydroindolone (15)⁴ in 42 and 36% yields, respectively. The ¹H-NMR spectrum of 14 showed it to be a mixture of two diastereoisomers (*cis* and *trans* relationships between the phenylthio and the methylthio groups) in a ratio of *ca.* 2:1. The formation of 15 appears to be the result of an acid-catalyzed elimination of benzenethiol from the initial cyclization

product (14). Indeed, when the period of heating of 12 was extended up to 30 min, the tetrahydroindolone (15) was obtained as a sole product in 65% yield.

On the other hand, heating the disulfoxide (13) in the presence of TsOH (1 equiv.) in boiling 1,2-dichloroethane for 5 min gave only the tetrahydroindolone (15) in 60% yield. A bulky phenylsulfinyl group of the initial cyclization product (16) might be in positions *trans* to the adjacent methylthio group, and hence a thermal elimination of benzenesulfenic acid appeared to occur rapidly to give 15.

Our attention was next turned to the Lewis acid-promoted cyclization of the chlorosulfide (17), which was prepared (quant.) from the corresponding sulfide (11) by treating with NCS. When the chlorosulfide (17) was exposed to a stoichiometric amount of TiCl₄ in CH₂Cl₂ at room temperature for 1 h, two indolone derivatives were obtained. One of them was the compound (14) (30% yield: a ca. 5:1 mixture of two diastereoisomers) which was identical to that obtained from 12. Interestingly, another one was proven to be an unexpected product (18) (34% yield). The ¹H-NMR spectrum of 18 exhibited the signals at δ 5.51 (dt, J = 1.7, 4.7 Hz) and δ 5.85 (br s) due to the olefinic protons at the C7 and C3 positions, respectively.

In order to see the mechanism for the formation of 18 (probably from 14), several experimentations were carried out with TiCl₄ and HCl gas, the latter of which might arise during the formation of 14 from 17. When compound (14) was treated either with a stoichiometric amount of TiCl₄ or with HCl gas in CH₂Cl₂ at room temperature, only the starting material was recovered unchanged. However, treatment of 14 with TiCl₄ in the presence of HCl gas gave 18 in 29% yield together with an additional product (19) (30% yield). The structure of 19 was deduced from its ¹H-NMR spectrum⁴ and its chemical transformation: heating 19 with TsOH in benzene afforded 15 in 60% yield. One possible rationalization for the formation of 18 is based on the assumption that the methylthio group at the C3 position of the *trans*-isomer of 14 coordinates to TiCl₄ to give the sulfonium ion intermediate (20), and then the *anti*-elimination occurs by an attack of the chloride ion (derived from HCl) on the phenylthio group to give 18. This type of reaction, however, is inapplicable to the *cis*-isomer of 14 for the stereoelectronic reasons, and hence the *cis*-isomer is merely protonated to give the acyliminium intermediate (21). The phenylthio group of 21 undergoes 1,2-migration through the episulfonium salt 22 to give the observed 19.5

Thus we revealed that the 5-endo-trigonal cyclization of α -thiocarbocations generated from the sulfoxide (12) and the chlorosulfide (17) provided a new method for the synthesis of a different type of 1,4,5,6-tetrahydro-2*H*-indol-2-ones such as 15 and 18. An application of the method to the synthesis of lycorine and erythrina alkaloids will be reported in due course.
