### Abstract

The dissociation constants ( $K_1$  and  $K_2$ ) of the carboxy groups of ethylenediaminetetraacetic acid (H<sub>4</sub>L) and the dissociation constant ( $K_5$ ) of the protonated form H<sub>5</sub>L<sup>+</sup> were determined by pH-metric titration in the pH range 1.3-4.5 at variable concentrations of ammonium nitrate ( $\mu = 1.0-7.0$ ) in an aqueous solution ( $I = 25 \pm 0.05^\circ\text{C}$ ). The dissociation constants of the ammonium groups in H<sub>4</sub>L ( $K_3$  and  $K_4$ ) failed to be determined under the experimental conditions chosen. For KNO<sub>3</sub> and NaClO<sub>4</sub> ( $\mu = 1.2$ ), all  $K_1$ - $K_5$  constants were calculated. The complexation of H<sub>4</sub>L with copper(II) in the presence of the supporting electrolytes of the indicated concentrations was studied by spectrophotometry and pH-metric titration. In the strongly acidic region, the [CuH<sub>3</sub>L]<sup>+</sup> species was found to form, in addition to the diprotonated and monoprotated copper(II) complexonates. The equilibrium constants for the formation of the complexonates change nonmonotonically with increase in the concentration of ammonium nitrate. At comparable ionic strengths of the solutions created by KNO<sub>3</sub> ( $\mu = 1.2$ ), NH<sub>4</sub>NO<sub>3</sub> ( $\mu = 1.0$ ), and NaClO<sub>4</sub> ( $\mu = 1.2$ ), the effect of NaClO<sub>4</sub> is most pronounced: the equilibrium constants decrease by  $\sim 2$  units of logK for all the complexonates. The formation of the heteroligand complex [CuLNH<sub>3</sub>]<sub>2</sub><sup>-</sup> in the aqueous solutions of ammonium nitrate (pH > 6) was established by the spectrophotometric method. © 1998 MAEe cyrillic signK Hayka/Interperiodica Publishing.
