Introduction

Pseudomonas aeruginosa is a major opportunistic human pathogen which produces a large variety of secreted and cell-associated virulence factors. Since P. aeruginosa infections are difficult to treat due to the emergence of highly antibiotic resistant strains, alternative drug targets including virulence factors are currently being under investigation. Recently, it has been shown that P. aeruginosa uses similar virulence factors when infecting mammalian systems or non-mammalian hosts like the social amoeba Dictyostelium discoideum, the nematode Caenorhabditis elegans or the fruit fly Drosophila melanogaster (Hilbi et al., 2007; Alibaud et al., 2008).

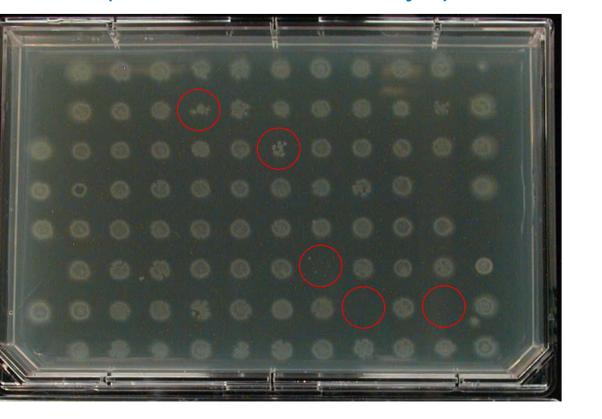

In this study, we used a comprehensive P. aeruginosa PA14 transposon mutant library (Liberati et al., 2006) to screen for mutants with reduced virulence. Furthermore, microarray analyses were performed to gain a deper insight into the interaction of *P. aeruginosa* with *D. discoideum*.

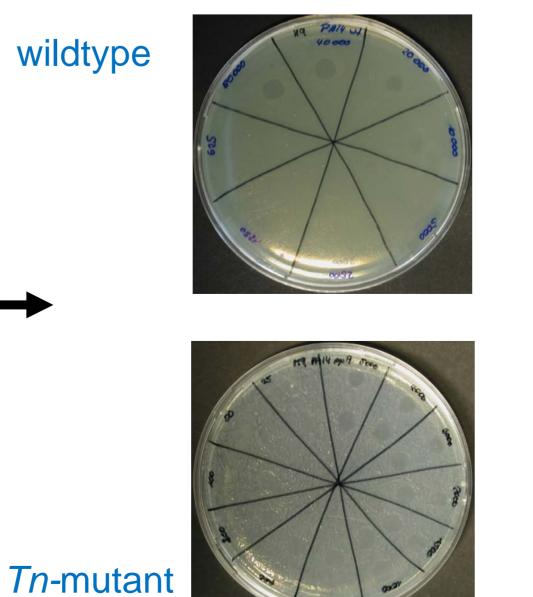

Identification of mutants with altered virulence phenotype

Minimum number of amoebae producing a halo (per 5 µl)

Summary

- Microarray analysis revealed ~500 genes differentially regulated in response to *D. discoideum*.
- Various virulence related genes including secondary metabolites, T6SS, Type IV pili and extracellular proteases and toxins were highly up-regulated.
- Type IV pili, secondary metabolites (e.g. PQS or pyochelin) and the twocomponent system cbrAB which is involved in the regulation of nitrogen/ carbon metabolism are crucial factors for *P. aeruginosa* to circumvent protozoan grazing.
