Abstract

The SEASALT project is a student's research campaign within the Education & Training programme of the European Fleet for Airborne Research (EUFAR). The project is an application of airborne in-situ measurement techniques in an Alpine valley atmosphere altered by man-made snow production. The efforts are influenced by the ongoing endeavours to link the climate and water-bidger related issues with the increasing use of artificial snow. The deployment of an instrumented aircraft (the ENDURO ultralight trike operated by the Forschungszentrum Karlsruhe) is aimed at capturing signatures of snow production within the regional water vapour budget and other related microphysical parameters by means of measurements of atmospheric composition as well as dynamic and thermodynamic properties. A summary of the experiment carried out during the two-week field campaign in Austria in February/March 2008 is presented.

Methodology

- constant-level flight legs along the valley axis
- ~ comparison of ski-resort surroundings with the rest of the valley
- vertical profiling by sounding-like flight legs (up to 2000 m)
- ~ description of Boundary Layer structure
- intensified ground-based measurements
- ~ reference for the 10-hour long airborne data-set

Time and location

- Enns river valley, Austria
- 2 weeks between Feb 23th and Mar 8th 2008

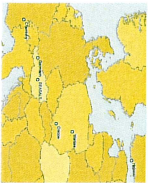

Figure 6: Snow-production in Haus (photo taken during rf03)

Selected instruments

- airborne (see fig. 1)
 - two aerosol size spectrometers covering 5mm – 20µm range (GRIMM WRAS system)
 - aerosol particle counter (TSI 3010)
 - two water vapour sensors: chilled mirror and IR absorption hygrometers
- ground-base (see fig. 7)
 - four meteorological stations along the valley: Niederoblahn, Groebming, Ramsau, Radstadt
 - eddy-covariance flux measurement station deployed in Niederoblahn

Figure 4: FZK-ENDURO ultralight trike

Few facts on snow-production

- snow produced by spraying water, containing crys-tallization nuclei, into atmosphere
- production efficient only in cold enough environment (dewpoint below -4°C)
- snow-production in Enns river valley: 581 snow-guns in Planau and 110 in Haus

Figure 5: A snow-gun in Haus (photo taken during rf03)

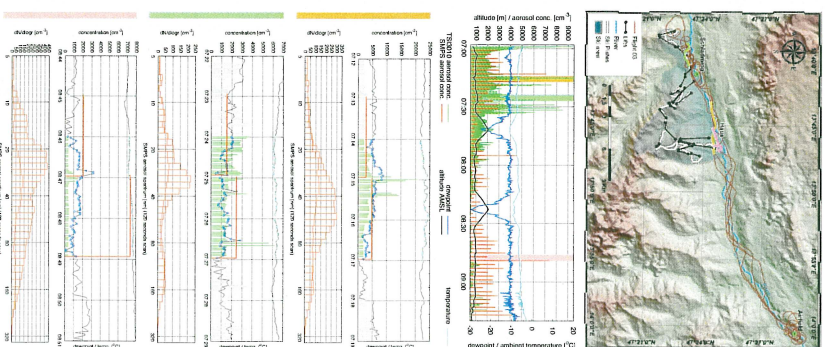

Figure 1: Aerosol and water vapour measurements (rf03): 07:14-07:17 UTC (overflying Haus, snow production running), 07:24-07:27 UTC (overflying Schladming, snow production running), 08:46-08:49 UTC (overflying Haus, no snow production for at least 40 minutes)

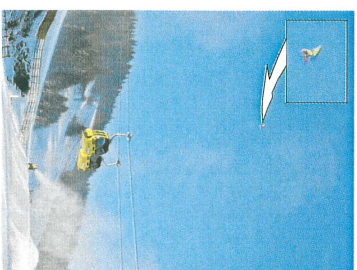

Figure 2: Photo of the FZK-ENDURO overflying a snow-gun in Haus taken at 07:15:22 UTC

Figure 3: Photo of the FZK-ENDURO overflying a snow-gun in Schladming taken at 07:46:52 UTC

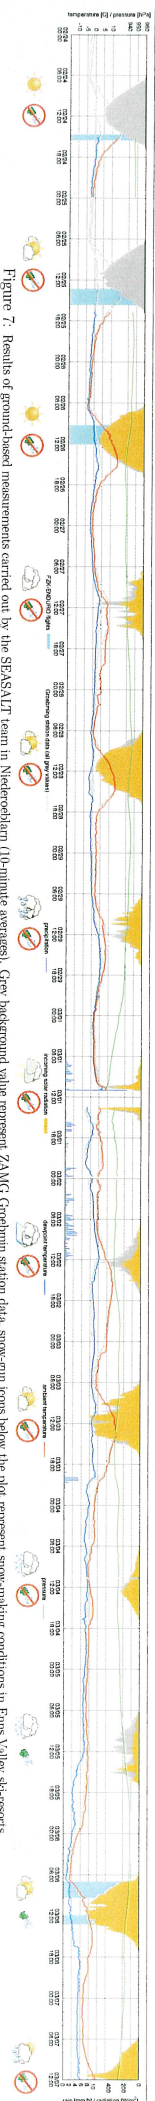

Figure 7: Results of ground-based measurements carried out by the SEASALT team in Niederoblahn (10-minute averages). Grey background value represent ZAMG Godehalm station data, snow-gun icons below the plot represent snow-making conditions in Enns Valley ski-resorts

The SEASALT campaign was funded by the EUFAR within the Education & Training framework. The poster was presented during the CR11 Artificial Snow and Climate Change - physical, social and economic assessment poster session on the ECU 2008 in Vienna. The SEASALT team expresses their appreciation for help, equipment and resources offered by: Planau-Hochwurzzen-Bahnen GmbH (campaign-related alteration of snow-making schedule), Niederoblahn Airport staff (office space, hosting of ground-based instruments), Zentralanstalt für Meteorologie und Geodynamik (access to ground-based meteor data), Institut für Meteorologie und Klimaforschung, Forschungszentrum Karlsruhe (ground-based flux station), Institute of Geophysists, University of Warsaw (ground-based sensors, administrative support), Finnish Meteorological Institute (access to meteor data), EDYTEM Laboratory, CNRS, University of Savoie (ground-based equipment), NASA (access to DEM of Enns River valley), Hausser Kaibling (data on snow production).
