Abstract

Thioxanthenes – being readily available in one step from thiosalicylic acid and arenes – were used in ruthenium-catalyzed C–H activation reaction to produce 1-mono- or 1,8-disubstituted thioxanthenes in good to excellent yields. Scope and limitation of this reaction are presented.

Introduction

Thioxanthenes (Figure 1) belong as a unique member to the large group of benzoannelated heterocycles [1]. They have found extensive use in biomedical applications (drugs and other bioactive compounds [2–5]) and material sciences, e.g., as photosensitizers (e.g., isopropylthioxanthone or diethylthioxanthone) [6–8] or as ligands [9,10]. Despite the widespread occurrences, there are only few modular syntheses reported so far and photosensitizing materials are often used as undefined mixtures. In addition, functionalization reactions for thioxanthenes, such as C–C-bond formations [11,12], are underdeveloped [13]. For example, there are only a handful of 1,8-dialkyl/aryl-functionalized thioxanthenes known [14–16], while more than 500 1-substituted thioxanthenes are reported according to Scifinder. In contrast, xanthone chemistry aiming at a high degree of substitution seems to be well explored [17,18].

**Figure 1:** Thioxanthone (1a).

This fact motivated us to extend existing methods [14,15] for the synthesis of substituted thioxanthenes. We were intrigued by the fact that carbonyl-substituted arenes can undergo a smooth C–H activation and alkylation in the presence of metal catalysts [19] (for general reviews see [20,21]). However, there are only few examples [14,15] with sulfur-containing hetero-

cycles as in general sulfur inhibits the catalytic activity of many transition metal catalysts [22].

Results and Discussion

Synthesis of functionalized thioxanthenes

The required thioxanthenes **1** were prepared using standard procedures [1,23]. For certain examples, optimizations of the standard protocol were required (Table 1 and Supporting Information File 1).

In case of methoxyarenes this method was not successful due to a partial ether cleavage catalyzed by hot sulfuric acid. In this case, methylation (Me_2SO_4 , K_2CO_3) of the hydroxythioxanthenes **1c**, **1e** and **1g** provided the required methyl ethers **1d**, **1f** and **1h**, respectively in good yields (80, 85 and 95%), Scheme 1.

Ru-catalyzed C–H activation

Following the precedence for other carbonyl compounds, we used the protocol of Murai et al. [19] to investigate the use of thioxanthenes in this C–H-alkylation reaction (Scheme 2). For recent examples and reviews, also for related rhodium-catalyzed systems, see [24–38].

It should be noted that already in the pioneering work there are also examples using sulfur heterocycles such as thiophene derivatives [19]. Gratifyingly, the reaction of dimethyl-substituted thioxanthone **1b** with the model olefin neohexene (3,3-dimethyl-1-butene, **4a**) was successful and the product **1ba** was obtained in 65% yield (Table 2, entry 4). This and all the prod-

tuted thioxanthone **1b** with the model olefin neohexene (3,3-dimethyl-1-butene, **4a**) was successful and the product **1ba** was obtained in 65% yield (Table 2, entry 4). This and all the prod-

ucts obtained exhibit exclusively *n*-alkylation – branched alkyl chains originating from addition at the 2-position were not found. Other olefins like 1-hexene (**4b**) or 3-phenylpropene (**4c**) also worked smoothly (Table 2, entries 5 and 6). In addition, the silyl-substituted olefin **4d** was also successfully used in this reaction (Table 2, entry 7). The product **1bd** is formed in good yield, however, it is prone to hydrolysis thus the isolated yield of the pure product was rather low. In contrast to literature

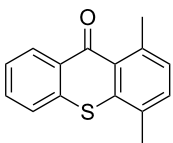

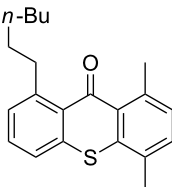

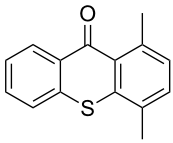

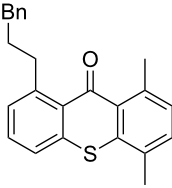

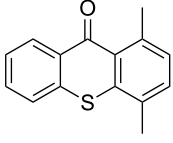

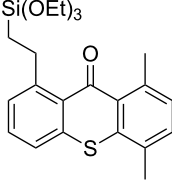

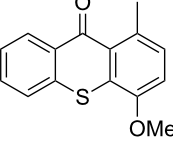

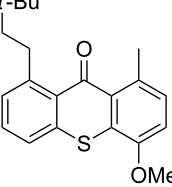

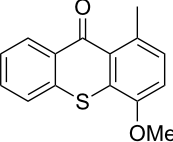

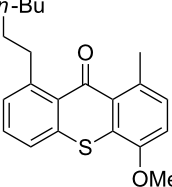

precedence for other carbonyl compounds [19], other olefins (styrene, vinyl/allyl ethers, perfluoroalkylethenes) failed since they polymerize during the reaction.

Extension of the unsymmetrical heterocycle system **1b** to the unsubstituted thioxanthone (**1a**) was also successful: Depending on the amount of alkene, mono- (Table 2, entry 3) or 1,8-disubstituted thioxanthenes such as **1aa_{bis}** or **1ab_{bis}** were

isolated (see Table 2, entries 1 and 2). In addition, other thioxanthenes such as **1h** are also suitable substrates (Table 2, entries 8 and 9).

However, other thioxanthenes such as a phenanthrene-annulated thioxanthone (not shown) failed to give the desired products due to insolubility of the starting materials.

Conclusion

We have presented a C–H-activation route towards the preparation of functionalized thioxanthenes. Despite the fact that mono- and disubstituted thioxanthenes can be found starting from the parent system, the selectivity can be controlled using

different stoichiometries. It should be noted that alkoxy and silyl functionalities are tolerated in the reaction.

Experimental

The catalyst $\text{RuH}_2(\text{CO})(\text{PPh}_3)_3$ was prepared according to literature [19] and stored under Argon with exclusion of water.

General procedure for C–H activation

In a sealed Schlenk pressure tube, 1.00 mmol of the thioxanthone, 0.060 mmol (55 mg) $\text{RuH}_2(\text{CO})(\text{PPh}_3)_3$, 1.2 to 6 mmol of the olefin and 2 mL toluene were stirred and heated to 135 °C for 12 h. After cooling, the solvent was evaporated

under reduced pressure and the residue submitted to column chromatography on silica gel using cyclohexane/ethyl acetate as eluent.
