Abstract—By taking advantage of a wideband bow-tie antenna in the Yagi configuration, a novel multilayer-stacked ultra-wideband (UWB) Yagi antenna is proposed. First, the fundamental 3-layered UWB Yagi model is studied with respect to a few critical dimensions. Then, several directors are added to form a multilayer-stacked Yagi antenna, where the width of the directors is optimized in a monotonic decreasing manner. A sixlayered UWB Yagi antenna is studied by simulations. It covers 3.4-10.6 GHz with its return loss better than 10 dB, and it achieves a high directivity up to 13 dBi and a relative cross-polar level better than -10 dB in the whole band.

Keywords—Multlayer-stacked; UWB; Yagi-Uda antenna

I. INTRODUCTION

FCC in 2002 declared the ultra-wide band (UWB) ranging from 3.1 GHz to 10.6 GHz as a license free band. During recent decades, the UWB antennas have found many applications in radar, telecommunications, wireless sensor networks, remote sensing and so on [1]-[4]. In recent years, Yagi and quasi-Yagi antennas have drawn much attention because of high gain and simple structure [5]-[6]. In our previous research on feeds for reflector antennas, we presented the gain enhancement and matching improvement of a bow-tie antenna with a stacked parasitic patch on top [7]. The present study extends the use of the parasitic patches and investigates the effect of various parameters on antenna performance.

II. FUNDAMENTAL 3-LAYERED UWB YAGI MODEL

First, a planar bow-tie dipole is investigated as a driver of the Yagi antenna, whose petal is constructed by a rectangular and a semicircular patch, whereas the central of the dipole is cut into straight edges for connecting an UWB balun to a ground plane. The surface currents of the driver dipole at 3 and 11 GHz are simulated by *HFSS*, as shown in Fig. 1. It can be observed that most of the currents is distributed along the edges near the feed gap at both frequencies. Therefore, a number of closely-spaced identical parallel patch bars can be used as directors, as shown in Fig. 2(a). If we increase the width of the bars and reduce the spacing until they join together, then the patch bars will be evolved into a solid patch, as depicted in Fig. 2(b). The S-parameter and co- and crosspolar far-field components of the patch bars and the solid patch are compared by using CST MWS. The results exhibited in Fig. 2(c) and (d) indicate that the two director configurations lead to very similar performance in both matching and radiation. For convenience, we use the solid patch for the director design.

Fig. 2. Director evolution: (a) parallel-bars director, (b) solid patch director, (c) S-parameters, (d) co- and cross-polar directivities of the two configurations

The fundamental 3-layer-stacked Yagi antenna model is drawn in Fig. 3. The antenna is with air-substrate and consists of a planar bow-tie dipole as the driver, a patch as the director and the ground plane as the reflector, which are all made of copper plates with a uniform thickness 0.5 mm. The driver dipole is fed by an UWB balun in connection with a coaxial cable that passes through the ground plane from beneath. Detailed dimensions are given in Table I.

Parameter	Lx	Ly	Dx1	Dy1	H1	H2	D1	S1	S 2
Voluo	60	60	24	12	5	13	26	4.4	16

III. 6-LAYER-STACKED UWB YAGI MODEL

Based on the 3-layer-stacked model, we simply add more identical directors with same spacing H1 (see Fig. 3(c)) above the first director to form a multilayer-stacked UWB Yagi antenna. The relationship between its maximum gain in the operating ultra-wideband and the number of directors is investigated and compared with the linear narrow-banded Yagi antenna [8], as shown in Fig. 4(a). It can be found that the two Yagi antennas have a very similar trend for the gain curves, which indicate a saturation on the gains when the number of directors hits a certain value, 8, in this case; meanwhile, the gain of the UWB Yagi model is greater than its counterpart when the director number of the two is same.

Fig. 4. (a) The gain versus the number of directors (the green curve is by courtesy of [8]), (b) A 3D view of a Yagi model with 4 directors.

Shown in Fig. 4(b) is a 6-layer-stacked model, for compromise on the gain and the compactness. However, the S_{11} parameters as well as the directivities of the 6-layered model with identical directors are not so good in the upper band (see Fig. 5). In order to improve the performance, the y-axis width of the 4 directors is optimized in a monotonic decreasing manner, while the x-axis length and the z-axis spacing are kept same as previous. Fig. 5 clearly shows that

the model with decreased-width directors performs as well as the one with equal-width directors in the lower band, while the former greatly outperforms the latter in the upper band; the S_{11} parameter is better than -10 dB over 3.4-10.6 GHz, the directivities vary around 8-13 dBi and the relative cross-polar level is below -10 dB in the whole band.

Fig. 5. (a) S_{11} and (b) co-polar directivity and cross-polar directivity vs. different y-axis width directors. The marking of 12 10 8 6 means the width of the 1^{st} (closest to the driver dipole), 2^{nd} , 3^{rd} and 4^{th} director, respectively.

IV. CONCLUSION

A six-layer-stacked UWB Yagi antenna has been proposed and optimized. The antenna can operate over 3.4-10.6 GHz with return loss better than 10 dB, the directivity between 8-13 dBi, and the relative cross-polar level below -10 dB. Compared with the linear narrow-banded Yagi antenna with the same gain, this UWB Yagi antenna is more compact by using fewer directors, a candidate for UWB communication applications.
