1
2
3 44 **ABSTRACT**
4

5 45 **Objective:** To determine whether multifactorial falls prevention interventions are effective in
6
7 46 preventing falls, fall injuries, ED re-presentations and hospital admissions in older adults
8
9 47 presenting to the ED with a fall.

10
11
12 48 **Design:** Systematic review and meta-analyses of randomised controlled trials (RCTs).
13

14 49 **Data sources:** Four health-related electronic databases (Ovid MEDLINE, CINAHL, EMBASE
15
16 50 and The Cochrane Central Register of Controlled Trials) were searched (inception to June 2018),
17

18
19 51 **Study selection:** RCTs of multifactorial falls prevention interventions targeting community
20
21 52 dwelling older adults (≥ 60 years) presenting to the ED with a fall with quantitative data on at
22
23 53 least one review outcome.
24

25 54 **Data extraction:** Two independent reviewers determined inclusion, assessed study quality and
26
27 55 undertook data extraction, discrepancies resolved by a third.
28

29
30 56 **Data synthesis:** Twelve studies involving 3,986 participants, from six countries, were eligible for
31
32 57 inclusion. Studies were of variable methodological quality. Multifactorial interventions were
33
34 58 heterogeneous, though the majority included education, referral to healthcare services, home
35
36 59 modifications, exercise, and medication changes. Meta-analyses demonstrated no reduction in
37
38 60 falls (rate ratio=0.78; 95% CI 0.58, 1.05), number of fallers (risk ratio=1.02; 95% CI 0.88, 1.18),
39
40 61 rate of fractured neck of femur (risk ratio=0.82; 95% CI 0.53, 1.25), fall-related ED
41
42 62 presentations (rate ratio=0.99; 95% CI 0.84, 1.16), or hospitalisations (rate ratio=1.14; 95% CI
43
44 63 0.69, 1.89) with multifactorial falls prevention programmes.
45
46
47

48 64 **Conclusions:** There is insufficient evidence to support the use of multifactorial interventions to
49
50 65 prevent falls or hospital utilisation in older people presenting to ED following a fall. Further
51
52 66 research targeting this population group is required.

80

81 What is already know about this subject:

- 82 • Falls are a leading reason that older adults present to emergency departments (EDs).
- 83 • There is systematic review evidence for interventions to reduce falls in older people
- 84 living in the community.
- 85 • When similar interventions are applied to those presenting to the ED with a fall, there is
- 86 a lack of effectiveness.

87

88 What this study ads:

- 89 • There remains little evidence to support the use of multifactorial falls prevention
- 90 programmes for older adults that present to ED with a fall.
- 91 • More studies in this complex population are required.

Confidential: For Review Only

101 INTRODUCTION

102 Falls are a leading cause of emergency department (ED) presentations in older adults^{1,2}. In the
103 United States (US), an older adult is treated in the ED for a fall every 15 seconds, and an older
104 adult dies following a fall every 29 minutes³. It is estimated that £2.3 billion is spent annually on
105 fall-related injuries in people over the age of 65 in the United Kingdom (UK)⁴. Age-standardised
106 rates of hospitalised fall-related injury cases in older Australians are also steadily increasing⁵. Fall-
107 related presentations to the ED are not isolated events; older patients frequently experience
108 subsequent falls (46% to 56%)⁶; re-hospitalisation (49%)⁷, and substantial functional decline⁷ in
109 the 12 months following ED presentation.

110
111 Clinical practice guidelines in the US, UK and Australia recommend the use of multifactorial
112 interventions that involve an assessment of individual risk factors, followed by specific
113 interventions targeted to those identified risk factors, to prevent falls in older adults living in the
114 community^{4,8,9}. A number of systematic reviews have also established evidence for the
115 effectiveness of multifactorial interventions in reducing falls in community dwelling older
116 adults¹⁰⁻¹³. However, there is conflicting evidence regarding the effectiveness of these
117 interventions when applied specifically to those presenting to the ED with a fall, based on
118 findings from a systematic review of available evidence until March 2007, conducted by Gates
119 and colleagues¹¹. Similarly, a more recent systematic review concluded that falls prevention
120 interventions found to be effective in the general older population did not appear to be
121 transferrable to those recently discharged from hospital¹³. These conflicting results are likely
122 because of the different care needs of the populations concerned¹⁴. There is a lack of current
123 evidence on the effectiveness of fall prevention interventions for older people presenting to the
124 ED with a fall, who have different care needs to their community-dwelling peers and those who
125 have been recently discharged from hospital¹⁵.

126

1
2
3 127 An updated review of the effects of multifactorial interventions in people presenting to the ED
4
5 128 is warranted, given the addition of new published trials, the increasing number of older people at
6
7 129 risk¹⁶, the major physical and psychological consequences associated with falls^{17,18} and high
8
9 130 associated healthcare costs¹⁹. The purpose of this review was to determine the effects of
10
11 131 multifactorial falls prevention interventions on falls, fall injuries, fractures, ED presentations and
12
13 132 hospitalisations in older adults presenting to the ED with a fall. The results will be of importance
14
15 133 to healthcare services and policy makers considering the high cost of the associated injuries and
16
17 134 management, and the costs associated with implementing such interventions²⁰.

136 **METHODS**

137 A systematic review and meta-analysis was performed according to the criteria of the Preferred
138 Reporting Items for Systematic Reviews and Meta-analyses.²¹

139

140 **Search strategy and selection criteria**

141 Four electronic databases (Ovid MEDLINE, CINAHL, EMBASE and The Cochrane Central
142 Register of Controlled Trials (CENTRAL)) were searched, from inception to June 2018. A
143 sensitive search strategy was developed using medical subject heading (MESH) search terms and
144 keywords (Appendix 1 outlines full Medline search strategy), and was customised to each
145 database as needed. References of included studies were reviewed for further relevant literature.

146

147 **Eligibility criteria**

148 Study inclusion criteria: (1) randomised controlled trials (RCT) published in English; (2) included
149 participants aged 60 years or older who presented to an ED after a fall; (3) the intervention
150 included any multifactorial falls prevention intervention delivered to the target population
151 (multifactorial interventions were defined as including two or more sub-domains of interventions
152 provided to participants in any possible combination that addresses two or more individual risk
153 factors for falls from assessment findings²²); and (4) at least one fall or hospitalisation outcome
154 was reported. Falls prevention interventions were classified according to the Prevention of Falls
155 Network Europe (ProFaNE) taxonomy²². Fall outcomes included the number or rate of falls,
156 fallers (number of people who experienced one or more falls in the follow-up period), fall-related
157 injuries or fractures. Hospitalisation outcomes included ED re-presentations or hospital
158 admissions. Studies that included participants who were recruited from an alternative setting (e.g.
159 primary care or community setting) were excluded from this review.

160

161 **Study selection and data extraction**

1
2
3 162 Initially, two reviewers independently screened and excluded studies based on title and abstracts.
4
5 163 For articles not excluded, full-text versions were independently assessed by both reviewers to
6
7 164 determine if they met inclusion criteria. In the event of multiple reports from one trial, only the
8
9 165 study with the most complete reporting was retained. Disagreements were resolved by a third
10
11 166 reviewer if required. Reviewers independently extracted data from included studies.
12
13 167 Demographic information (including country of origin, population specifications, sample size),
14
15 168 definitions for fall and hospital outcomes and intervention characteristics (such as falls-risk
16
17 169 assessments, healthcare professional undertaking the assessment, the intervention strategies used,
18
19 170 timing and intensity of interventions offered, and participation) were extracted using a
20
21 171 standardised data extraction form. Data available for all relevant outcomes were extracted and
22
23 172 tabulated.
24
25
26
27
28
29

30 174 **Methodological quality assessment**

31
32 175 All included studies were assessed for methodological quality by the same reviewers using the
33
34 176 PEDro scale²³. This scale rates 11 aspects of methodological quality of RCTs as being either
35
36 177 absent or present. A third reviewer was called upon if consensus could not be reached.
37
38
39

40 178 41 179 **Data synthesis and meta-analysis**

42
43 180 Study characteristics and demographic data, such as sample size, gender, and age of participants
44
45 181 were reported using mean (SD), median (IQR) or frequency. Meta-analysis was conducted to
46
47 182 assess the effect of multifactorial interventions on review outcomes. The rate ratio and 95%
48
49 183 confidence interval (if available) was used to describe the treatment effect for falls, fractures, ED
50
51 184 presentations and hospitalisations. For the outcome of faller versus non-faller, we used the risk
52
53 185 ratio and 95% confidence interval as the treatment effect. If both adjusted and unadjusted effect
54
55 186 estimates were reported, we used the unadjusted estimate unless the adjustment was for
56
57 187 clustering. Effect estimates were manually calculated when needed. When a study reported
58
59
60

1
2
3 188 multiple effect estimates for an outcome, the follow up most comparable with other studies, or
4
5 189 with the longest follow-up, or adjusted for the largest number of covariates was selected. We
6
7 190 conducted two pre-planned subgroup analyses; 1) based on frequency of interventions
8
9
10 191 (interventions with two or more interactions versus those that included less than two), and 2)
11
12 192 type of interventions included (interventions including only referral based interventions versus
13
14 193 those that included direct treatment to address risk factors).

15
16 194
17
18 195 As heterogeneity of data was anticipated, due to differences in study populations, follow-up
19
20 196 duration and intervention components, a random effects model was used. An inverse variance
21
22 197 method was also used to weight each estimate. Between-study variability was assessed using the
23
24 198 I^2 statistic²⁴, where I^2 values greater than 50% were considered to have a high degree of statistical
25
26 199 heterogeneity²⁵. Where data was unable to be pooled in a meta-analysis due to heterogeneity of
27
28 200 outcome measures, descriptive analysis was performed. All analyses were conducted with the use
29
30 201 of Review Manager, version 5.2 (RevMan, The Cochrane Collaboration; Oxford, UK).

203 **RESULTS**

204 **Search yield**

205 The electronic search identified 851 potential studies for screening of eligibility, after duplicate
206 studies were removed. Following screening of titles and abstracts and full-text review, 12 studies
207 were retained for inclusion (Figure 1), based on our described inclusion and exclusion criteria.

208 There were a total of 3,986 participants in the trials included. The median number of participants
209 randomised per trial was 340 (range 109²⁶ to 712⁶). Mean age was 78 years and ranged across
210 studies from 73²⁷ to 84²⁸ years. Average gender mix was 69% female (ranging from 55%²⁷ to
211 80²⁹%).

212

213 <<Insert Figure 1>>

214

215 **Study and sample characteristics**

216 The 12 included studies were published between 1999 and 2018 and conducted in six countries
217 (Table 1). Population age was specified as equal or greater than 65 years in all studies except
218 two^{6,27}, which included those 60 years and above. Ten studies excluded participants with
219 cognitive impairment, although definitions varied across studies. Five studies utilised the Mini
220 Mental State Examination (MMSE) (score ranging from 16 to ≥ 25), three the Abbreviated
221 Mental Test (AMT) (scores ranging from 4 to ≥ 7) and two did not use a validated tool (patients
222 were excluded based on being described as having dementia in hospital records). Only one study
223 included older people with cognitive impairment (MMSE < 24)²⁹.

224

225 <<Insert Table 1>>

226

227 **Methodological quality of included studies**

228 Studies were of variable methodological quality (Table 1). Methodological strengths included
229 allocation concealment and between-group comparisons for statistical analysis. Common
230 limitations were the lack of blinding and inadequate follow-up of participants. The complete
231 PEDro assessment of studies have been outlined in Appendix 2 in the supplementary data on
232 the journal website.

233

234 **Multifactorial falls assessment and interventions**

235 All studies included an assessment of falls risk factors (Appendix 3 provides a detailed summary).
236 Assessment tools and risk factors assessed varied considerably across studies, as did the type of
237 healthcare professionals undertaking the assessments. The most common falls risk factors
238 assessed were home environment (10 studies), mobility or gait (9 studies), vision (10 studies) and
239 balance (7 studies). The time from index fall until baseline assessment was described in five
240 studies, and ranged from within two weeks to one month after the fall-related ED presentation.
241 Assessments were also undertaken in a variety of settings and on occasion by more than one
242 health professional, including the participant's home (10 studies), an outpatient setting e.g. day
243 hospital or clinic (4 studies) or as an inpatient (2 studies).

244

245 Table 2 provides a detailed summary of the interventions of included studies. Interventions were
246 led by a variety of healthcare professionals, including occupational therapists, physiotherapists,
247 registered nurses and medical professionals. The specific interventions delivered were highly
248 variable, including education (11 studies), referral to healthcare services (11 studies), home
249 modifications (8 studies), exercise (6 studies) and medication change (5 studies). Some studies
250 provided only limited treatment options, such as education and referral to healthcare services,
251 whilst others provided many potential intervention strategies. The time until delivery of
252 intervention was reported in only six studies, and ranged from two to eight weeks after

1
2
3 253 completion of baseline assessment. Frequency of the recommended interventions varied from
4
5 254 one to up to 16 sessions. Only six of the 12 included studies reported on patient uptake of
6
7 255 referrals and/or fall prevention recommendations, ranging from 7%⁶ to 100%²⁸.
8
9

10 256

11
12 257 <<Insert Table 2>
13

14 258

15 259 **Outcome measures**

16
17
18 260 A number of fall outcomes were captured across the 12 studies (Table 1). Studies used varying
19 261 definitions for these outcomes, summarised in Appendix 4. All studies utilised falls calendars or
20 262 diaries to record information on falls. Of these, 11 studies required participants to return the
21 263 calendar regularly (weekly, monthly), nine contacted the participants monthly to verify/retrieve
22 264 falls data from the calendar, whilst one collected data only on follow-up (12 months)³⁰. All
23 265 studies, except one³¹ that included ED presentations and/or hospital admissions as an outcome
24 266 measure, assessed medical records to confirm details. The length of follow up for studies was
25 267 between six and 12 months.
26
27
28
29
30
31
32
33
34
35
36

37 268

38 269 **Effectiveness of falls prevention interventions**

39 270 *Rate of falls and number of fallers*

40
41
42 271 As shown in Figure 2a, there was no reduction in the rate of falls (rate ratio 0.78, 95% CI 0.58 to
43 272 1.05) with the use of multifactorial falls prevention programmes. Nor did the programmes
44 273 significantly reduce the number of fallers (risk ratio 1.02, 95% CI 0.88 to 1.18; Figure 2b).
45
46 274 Substantial statistical heterogeneity was noted between individual studies for both the rate of falls
47 275 ($I^2=94\%$) and the number of fallers ($I^2=75\%$). Subgroup analyses demonstrated that studies that
48 276 included two or more interactions in their multifactorial intervention programme had a
49 277 significant reduction in the rate of falls (rate ratio 0.62, 95% CI 0.45 to 0.86) (Appendix 5).
50
51
52
53
54 278 Similarly, studies which included treatment of risk factors, rather than just referral based
55
56
57
58
59
60

279 interventions, demonstrated a significant reduction in the rate of falls (rate ratio 0.78, 95% CI
280 0.58 to 0.93). No difference was observed for number of fallers in these subgroups.

281

282 *Fall injuries and injurious falls*

283 Meta-analyses were not performed for fall injuries and injurious falls, as the definitions were too
284 heterogeneous across included studies (Appendix 4). However, of the eight studies that reported
285 on either injurious falls or fall injuries, no study observed a statistically significant effect.

286

287 *Number of fractures*

288 Due to the variability in the type of fractures reported, only studies that reported on the same
289 outcome of a fractured neck of femur (NOF) were included in this meta-analysis (3 studies).

290 Multifactorial falls prevention programmes did not significantly reduce the number of fractured
291 NOFs (risk ratio 0.82, 95% CI 0.53 to 1.25; Figure 2c). Of the remaining two studies that
292 reported on other fractures, one²⁷ reported a reduction in the rate of fractures in the intervention
293 group (incidence rate ratio 0.37, 95% CI 0.15 to 0.91). The other study⁶ observed no effect on
294 fractures.

295

296 *Rate of fall-related ED presentations and hospitalisations*

297 Due to the limited number of studies that reported all-cause ED presentations and
298 hospitalisations, only fall-related ED presentation or hospitalisation outcomes are reported. The
299 pooled data demonstrates no significant effect on the rate of fall-related ED presentations (rate
300 ratio 0.99, 95% CI 0.84 to 1.16; Figure 2d), or fall-related hospitalisations (rate ratio 1.14, 95% CI
301 0.69 to 1.89; Figure 2e). Statistical heterogeneity was noted between individual studies for
302 hospitalisations ($I^2=58\%$). Of the three studies that reported all-cause ED presentations and/or
303 hospitalisations, no study observed a statistically significant effect on either outcome. Subgroup

1
2
3 304 analyses did not identify any difference in the results for fractures, ED presentations or
4
5 305 hospitalisations.

15 309 **DISCUSSION**

17
18 310 This review extends upon previous reviews on the effect of multifactorial falls prevention
19
20 311 programmes^{10,12} focusing on the specific population of older adults who present to ED with a
21
22 312 fall. It includes seven additional studies published since the review by Gates and colleagues in
23
24 313 2007¹¹. We found that multifactorial intervention programmes did not reduce falls in older
25
26 314 people who present to the ED with a fall, unless the programme included two or more
27
28 315 interactions, or the treatment of risk factors, rather than referral-based interventions alone. No
29
30 316 significant reductions were observed in the number of fallers, fractured NOFs, ED presentations
31
32 317 or hospitalisations with the delivery of multifactorial falls prevention programmes. We were
33
34 318 unable to synthesise data relating to rates of injuries, due to the variability in how this outcome
35
36 319 was defined.
37
38
39
40 320

41
42 321 There are three key reasons that may have contributed to the limited findings of effect;
43
44 322 heterogeneity of multifactorial interventions, poor tailoring of interventions to the ED
45
46 323 population, and the inconsistent definition of outcomes between studies. The findings of this
47
48 324 review are consistent with findings from the recently updated Cochrane systematic review which
49
50 325 examined the efficacy of multifactorial interventions in community-dwelling older adults¹². As
51
52 326 observed by Hopewell et al. (2018), we noted substantial diversity between the multifactorial
53
54 327 interventions delivered within studies included in our review. Some studies managed multiple
55
56 328 risk factors with multiple intervention strategies from a variety of healthcare professionals over
57
58
59
60

1
2
3 329 numerous interactions, while others concentrated more on education and home modifications in
4
5 330 a single interaction. Studies also used various suites of multifactorial interventions. Although the
6
7 331 majority of studies included referral to relevant healthcare services and education, the location
8
9 332 and mode of delivery of the interventions were different. Based on results from our subgroup
10
11 333 analyses, programmes should at minimum include more than one interaction or actual treatment
12
13 334 of one or more risk factor, and not be purely referral based. Meta-analyses of the number of
14
15 335 fallers, rate of falls and rate of ED presentations showed significant statistical heterogeneity (I^2
16
17 336 58-94%). Whilst it is expected that multifactorial interventions will differ based on a person's
18
19 337 individual risk factors, the low number of studies and the heterogeneity observed may have
20
21 338 diluted any possible effects.
22
23
24
25
26
27

28 340 Many of the included interventions were not tailored specifically to the care needs of this
29
30 341 population group but were generic interventions that can be implemented to community-
31
32 342 dwelling older adults. People that present to the ED as a result of a fall, are generally older,
33
34 343 frailer, have higher risk of subsequent falls, have more multi-morbidity, complex social issues
35
36 344 and more severe injuries when compared to those who do not attend the ED^{15,37}. The ED is a
37
38 345 challenging environment in which to initiate falls prevention interventions as staff, workflows
39
40 346 and processes are focused on managing the acute care needs of a patient (e.g. injury assessment
41
42 347 and management) as opposed to prevention. The studies included in this review may not have
43
44 348 sufficiently addressed these differences.
45
46
47

48 349
49
50 350 Finally, our outcomes of interest were rate of falls, rate of ED presentations and hospitalisations,
51
52 351 number of fallers and number of fractures. Similar to the review by Hopewell and colleagues
53
54 352 (2018), it was apparent in our review that these outcomes were defined inconsistently across the
55
56 353 included studies. Definitions varied for falls and fall injuries. Some studies excluded specific
57
58 354 types of falls (for example, those due to an acute medical event or in which the person came to
59
60

1
2
3 355 rest on furniture or a wall) whereas others included all falls. The rate of peripheral fractures has
4
5 356 been recommended as the only robust and feasible measure of an injury^{12,38}. However, only
6
7 357 NOF fractures were able to be pooled in this review, due to varying definitions. As injuries
8
9 358 related to falls contribute to the significant burden on the health of patients, and the healthcare
10
11 359 system¹⁹, it is important that these more robust outcome measures are consistently defined and
12
13 360 reported to allow pooling of results in future reviews^{10,38,39}. The lack of effect on hospitalisation
14
15 361 outcomes may reflect the broader health concerns in this population.
16
17
18
19 362

20
21 363 Adherence to fall prevention recommendations and referrals is an important consideration when
22
23 364 assessing the efficacy of a falls prevention programme, particularly when numerous interventions
24
25 365 are being provided. However, we found adherence to be inconsistently reported. Previous
26
27 366 studies have found that participation and engagement in falls prevention programmes in general
28
29 367 community dwelling older adults is likely to be around 50% at 12 months⁴⁰. A likely contribution
30
31 368 to those that present to ED with a fall having poorer participation and engagement in fall
32
33 369 prevention programmes may be their complex health needs. Poor adherence could also be
34
35 370 explained by the “better for others than for me” phenomenon as described by Haines et al,
36
37 371 where individuals at risk of falls can see benefits in falls prevention interventions generally, but
38
39 372 do not adhere to these as they do not believe the interventions are relevant to them⁴¹. When
40
41 373 developing new interventions it is important to consider the full range of factors that may
42
43 374 influence the effectiveness of an intervention including factors that may limit engagement and
44
45 375 participation⁴⁰. Future research would benefit from exploring these factors this population group
46
47 376 in more detail.
48
49
50
51
52
53 377

54 378 **Study limitations**

55
56
57 379 This review was undertaken using the robust methods recommended in the PRISMA statement.
58
59 380 Limitations include the consideration of papers only published in English, potentially excluding
60

1
2
3 381 other high-quality studies, and the analysis of only objective outcomes (eg falls, fall injuries).
4
5 382 Subjective information regarding fear of falling, falls self-efficacy and health related quality of life
6
7 383 were not considered, which may have provided further insight into meaningful change in
8
9 384 psychological consequences of falls, that contribute to the overall burden. The majority of
10
11 385 studies also excluded older adults with significant cognitive impairment, which restricts
12
13 386 generalisability of this review's findings to those with delirium or dementia. All studies only had a
14
15 387 maximum follow-up period of 12 months. It is possible that different conclusions may result if a
16
17 388 longer follow-up was applied for these less sensitive measures. Despite the limitations, this
18
19 389 review reinforces the fact that falls prevention for this high-risk population is complicated and
20
21 390 current guidelines regarding falls prevention practices may need to be targeted specifically for
22
23 391 this population.
24
25

27
28
29

392

393 **Conclusion**

394 Falls and their sequelae are a significant health burden worldwide. This systematic review and
395 meta-analysis of randomised controlled trials found little evidence to support the use of
396 multifactorial falls prevention programmes for older adults that present to ED with a fall. More
397 studies in this complex population are required. Studies with a reproducible type and dose of
398 intervention, and powered to detect effects on fall injuries and fractures, are needed to resolve
399 the uncertainty of effectiveness of intervening in this population group. Research with consistent
400 definitions of fall outcomes, along with adequate reporting of intervention components, intensity
401 and adherence are crucial.

— Not reported

~ Included in assessment but no formal assessment tool used

† Time for assessment to delivered after fall/discharge from ED

‡ Assessment completed by one healthcare professional from one of the list professions

§ Two item screening tool was also used to assess falls risk

12 MD =Doctor; OT = Occupational Therapist; PT = Physiotherapist; MD = Medical doctor; RN = Registered Nurse; D = Dietitian; RF = Research Fellow

13 Home = Home visit or home based intervention; Tele = Telephone follow up calls; DH = Day Hospital; IP = Inpatient hospital; Group = Group program in out patient setting

14
15 FROP-Com = Falls Risk for Older People in the Community; Short FES-I = Falls Efficacy Scale–International (Short version); WHSA = Westmead Home Safety Assessment; Snellen = Snellen
16 chart; FHI = Falls handicap inventory; Checklist = Environment hazards checklist designed by the Health and Safety Executive, UK; OH = orthostatic/postural hypotension; POMS =
17 Performance Orientated Mobility Score; USER = User Safety and Environmental Risk checklist for home environment hazards; Romberg = The Romberg test of proprioception; FAI = Frenchay
18 Activities Index; GnG = Get up and Go; GARS = Groningen Activity Restriction Scale; CDC = Centers for Disease Control and Prevention Home Checklist; Checklist* = Assessment of
19 Environmental fall hazards using a standard checklist; Whisp = Whisper voice test; S-test = The 'S' test for selecting mobility aids within an institutional setting; ECG = Electrocardiography;
20 MFES = Modified version of the Falls Efficacy Scale; SPPB = Short Physical Performance Battery; mPOMA = modified version of the Performance Orientated Mobility Assessment; Checklist* =
21 Assessment of environmental fall hazards using a standard checklist; VAA = Visual acuity assessment; PPA = A physiological profile approach to fall risk assessment (short version); BBS = Berg
22 Balance Scale; DGI = Dynamic Gait Index; TUG = Timed up and go; 30STS = Sit to stand in 30 seconds

Appendix 4: Fall outcomes measured

| Reference | Outcome measure collected | Definition of fall outcomes | Data collection mode |
|--------------------|---|---|--|
| Barker 2018 | <p>Primary outcomes were falls and fall injuries per person-year over the 12-month study period. Falls may result in multiple injuries. As such, data on injurious falls (falls with at least one injury) were also recorded.</p> <p>Secondary outcomes included ED representations, hospitalisations, fractures (confirmed by radiological investigation) and deaths per person-year over the 12-month study period.</p> | <p>Fall: an event resulting in a person coming to rest inadvertently on the ground, floor or other lower level.</p> <p>Fall injury: any physical harm resulting from a fall (including fractures, dislocations, sprain, skin tears and bruising), reported by study participants.</p> | <p>Fall outcomes: Self-reported via monthly fall calendars and blinded assessor telephone calls</p> <p>Hospital utilisation: Self-reported via monthly fall calendars and blinded assessor telephone calls and verified using hospital administrative datasets</p> |
| Chu 2017 | <p>Primary outcomes included number of fallers and repeated fallers, number of falls and recurrent falls, time until first fall, number of ED visits because of falls, and length of hospital stays primarily due to falls in the 12-month follow-up period.</p> <p>Secondary outcomes included measurements during follow-up calls—telephone Barthel Index-50 (MBI), the Chinese version of the Frenchay Activities Index (FAI), and the Chinese version of the 4-item Geriatric Depression Scale (GDS).</p> | <p>Fall: an event that results in a person coming to rest inadvertently on the ground or hitting an object like a chair or stair. Individuals who fell because of excess alcohol intake or sustained a sudden blow or loss of consciousness or sudden onset of paralysis due to stroke or an epileptic seizure were excluded.</p> | <p>Fall outcomes: Self-reported via blinded assessor telephone calls to ask about subsequent falls</p> |
| Close 1999 | <p>Primary endpoint was subsequent falls</p> <p>Secondary outcomes were death, major injury, moves to institutional care, functional status, and use of health care.</p> | <p>Fall: inadvertently coming to rest on the ground or other lower level with or without loss of consciousness and other than as a consequence of sudden onset of paralysis, epileptic seizure, excess alcohol intake, or overwhelming external force.</p> <p>Fall injury: the number of serious injuries (fracture or joint dislocation)</p> | <p>Fall and healthcare utilisation outcomes: Self-reported via monthly calendars</p> |

| | | | |
|----------------|--|--|--|
| Davidson 2005 | <p>Primary outcome was the number of falls and the number of subjects who fell again during 1 year of follow-up.</p> <p>Secondary outcome measures were injury rates and fall-related hospitalisation, mortality, and changes in fall efficacy (Activities specific Balance Confidence Scale).</p> | <p>Fall: inadvertently coming to rest on the ground or other lower level with or without loss of consciousness or injury.</p> <p>Fall injury: not defined</p> | <p>Fall outcomes: Self-reported via monthly fall calendars and blinded assessor telephone calls</p> <p>Hospital utilisation: Self-reported via monthly calendars and blinded assessor telephone calls and verified with hospital records</p> |
| Harper 2017 | <p>Primary outcome measure was the fall frequency among patients between ED discharge and commencement with the falls specific service.</p> <p>Secondary outcomes were time from discharge to next fall, attendance rates at the falls specific service, reason for nonattendance and death.</p> | <p>Fall: any presentation where patients had come to rest on the ground, floor, or lower level.</p> | <p>Fall outcomes: Self-reported via monthly fall calendars and blinded assessor telephone calls</p> |
| Hendriks 2008 | <p>Primary outcome measures were falls (falls, recurrent falls, "injurious falls", and time to first fall) and daily functioning.</p> | <p>Fall: an event that results in a person coming to rest inadvertently on the ground or other lower level.</p> <p>Injurious fall: the percentage of participants who sought medical care after a fall.</p> | <p>Fall outcomes: Self-reported via monthly fall calendars and blinded assessor telephone calls</p> |
| Lightbody 2002 | <p>Primary outcome was further falls, consequent injury and subsequent place of treatment were recorded.</p> <p>Secondary outcome were functional ability, re-attendance at the Accident and Emergency Department and admission to hospital.</p> | <p>Fall: patient failing to maintain a stable position and inadvertently coming to rest on the ground or lower level, with or without loss of consciousness, but not as the result of acute medical events or extraordinary environmental factors. Coming to rest against furniture or a wall was not deemed a fall.</p> <p>Fall injury: not defined</p> | <p>Fall outcomes: Self-reported via monthly fall calendars and blinded assessor telephone calls</p> <p>Hospital utilisation: Self-reported via monthly calendars and triangulated with hospital and GP records</p> |
| Matcher 2017 | <p>Primary outcome measure was experiencing at least 1 fall during the 9-month study period.</p> <p>Secondary outcome measures were the occurrence of at least 1 injurious fall during the study period and a change in the Short Physical Performance Battery (SPPB) score.</p> | <p>Fall: an event which results in a person coming to rest inadvertently on the ground or floor or other lower level</p> <p>Injurious fall: a fall for which the participant sought medical attention or restricted his/her daily activities for at least 48 hours.</p> | <p>Fall outcomes: Self-reported via monthly fall calendars</p> |

| | | | |
|------------------------------|---|--|--|
| <p>Russell 2010</p> | <p>Primary outcome measures were falls and injuries as a result of these falls, over the 12-month follow-up period.</p> <p>Secondary outcome measures of serious injury (Abbreviated Injury Score >2) and peripheral fractures were summarised and compared using the same methods used for the primary outcomes.</p> | <p>Fall: based on the Kellogg International Working Group definition: “an event which results in a person coming to rest inadvertently on the ground or some lower level, and other than as a consequence of sustaining a violent blow, loss of consciousness, sudden onset of paralysis as in stroke or an epileptic seizure.”</p> <p>Injurious fall: number of participants sustaining a fall or injury</p> <p>Serious fall injury: Injuries sustained as a result of falling were assessed for severity using the Abbreviated Injury Score. Serious fall injuries = Abbreviated Injury Score >2</p> | <p>Fall outcomes: Self-reported via monthly fall calendars and blinded assessor telephone calls</p> <p>Hospital utilisation: Self-reported via monthly calendars and blinded assessor telephone calls and verified with hospital records</p> |
| <p>Shaw 2003</p> | <p>Primary outcome measure was number of participants who fell at least once in the year after intervention.</p> <p>Secondary outcome measures were number of falls (corrected for diary returns), time to first fall, injury rates, fall related attendance at accident and emergency department, fall related hospital admissions, and mortality.</p> | <p>Fall: an event reported by either the person who fell or a witness, resulting in the patient inadvertently coming to rest on the ground or at another lower level with or without loss of consciousness or injury</p> <p>Fall injury: major injury or fractured neck of femur</p> | <p>Fall outcomes: Self-reported via weekly fall calendars and blinded assessor telephone calls</p> <p>Hospital utilisation: Hospital computerized records</p> |
| <p>Vind 2009</p> | <p>Primary outcome of the study was total number of falls. Secondary outcome measures were number of injurious falls, fallers, frequent fallers (>3 falls per year), time to first fall and first injury.</p> | <p>Fall: unintentionally coming to rest on the floor, ground, or other lower level.</p> <p>Injurious fall: fall caused injury resulting in contact with a general practitioner, emergency department or admission to the hospital.</p> | <p>Fall outcomes: Self-reported via weekly fall calendars and blinded assessor telephone calls</p> <p>Hospital utilisation: Hospital computerized records</p> |
| <p>Whitehead 2003</p> | <p>Principal outcome measure was the uptake of recommended evidence-based strategy at six months. Self-reported fall rate over the ensuing six month period was also assessed.</p> | <p>Fall: inadvertently coming to rest on the ground or other lower level with or without loss of consciousness and other than as a consequence of a major intrinsic or extrinsic event.</p> | <p>Fall outcomes: Self-reported via weekly fall calendars and blinded assessor telephone calls</p> |

Appendix 5: Sub-group analyses for falls

a) Meta-analysis by intensity of treatments

b) Meta-analysis by type of treatments i.e. referrals vs other
