

TRUST BASED FLOODING ATTACK DETECTION AND RESPONSE MECHANISMS FOR AD HOC ON-DEMAND DISTANCE VECTOR ROUTING PROTOCOL

BAHRAM YAGHOUBZADEH ASHOURUAN

A project report submitted in partial fulfillment of the
requirements for the award of the degree of
Master of Computer Science (Information Security)

Faculty of Computer Science and Information Systems
Universiti Teknologi Malaysia

JANUARY 2013

This project report is dedicated to my beloved wife, father, mother and sister for their endless support and encouragement.

ACKNOWLEDGEMENT

First and foremost, I would like to express heartfelt gratitude to my valued supervisor **DR. SHUKOR ABD RAZZAK** for his constant support during my study at UTM. He inspired me greatly to work in this project. His willingness to motivate me contributed tremendously to our project. I have learned a lot from him and I am fortunate to have him as my mentor and supervisor.

Besides, I would like to thank the authority of Universiti Teknologi Malaysia (UTM) for providing me with a good environment and facilities to complete my master program and this project.

ABSTRACT

Mobile Ad hoc Networks provide a structure-less environment, enabling participants in the coverage mobile nodes to communicate each other without using any centralized authentication agent. Thus, it is compromised in face to various sorts of attacks. Unfortunately, none of the presented secured routing protocols can detect internal Denial of Service (DoS) attacks by itself naturally. One of the most important and effective internal misbehaviors which has dramatic side effects on the network's throughput is Flooding Attack. This project aims at proposing an alternative solution to detect and respond Flooding Attack in MANET which is based on cooperative trust evaluation mechanisms. Actually, this approach is matched to basic principles of distributed networks in which the participating nodes are responsible for any needed creation, operation and maintenance of the network. Moreover, it seems useful for high mobility networks where the suspicious nodes move around the area repeatedly. Consequently, the gained results of the project prove that the proposed Trust-based Cooperation mechanisms decreases the side effects of Flooding Attack on Ad-hoc On-demand Distance Vector routing protocol.

ABSTRAK

Rangkaian Segera Bergerak (Mobile Adhoc Network) menyediakan persekitaran kurang berstruktur, membolehkan pengguna yang berada di dalam kawasan liputan untuk berkomunikasi di antara satu sama lain tanpa menggunakan sebarang agen pengesahan berpusat. Oleh itu, ia mampu berhadapan dengan pelbagai jenis serangan. Malangnya, tiada satu pun protokol laluan keselamatan tersebut dapat mengesan Denial of Service (DOS) dalaman yang diserang oleh diri sendiri secara semulajadi. Di antara kepentingan dan keberkesanan tingkahlaku dalaman yang memberi kesan sampingan kepada laluan rangkaian ialah *Serangan Banjir* (Flooding Attack). Projek ini bertujuan untuk mencari penyelesaian alternatif bagi mengesan dan bertindakbalas dengan *Serangan Banjir* dalam MANET yang mana ia berteraskan mekanisma penilaian kepercayaan kerjasama. Sebenarnya, pendekatan ini berpadanan dengan asas prinsip kepada rangkaian yang beredar / bergerak di mana node atau laluan yang turut serta adalah bertanggungjawab kepada sebarang keperluan yang dicipta, pengoperasian dan penyelenggaraan kepada rangkaian. Selain itu, ia sangat berguna untuk rangkaian bergerak yang tinggi di mana node yang mencurigakan bergerak mengelilingi kawasan tersebut secara berulang-ulang. Kesimpulannya, hasil keputusan yang diperolehi dari projek ini membuktikan bahawa cadangan mekanisma Trust-based Cooperation dapat mengurangkan kesan sampingan *Serangan Banjir* (Flooding Attack) kepada protokol laluan On-Demand Distance Vector.

CHAPTER 1

INTRODUCTION

1.1 Overview

Today, Mobile Ad-hoc Networks (MANET) have been popular because of its exclusive characteristics which have allowed wireless devices to connect each other easily when fall in the radio coverage of each other [1]. Also, each node performs the roles of an end-system and works also as a router to forward packet through the network; therefore, mobile ad hoc network uses the concept of multi hop communication. In addition, every node can move in the network freely. This mobility is as a result of dynamic topology in MANET without any infrastructure requirements such as centralized access point or centralized administration. As a result, each node is in charge of its security threats [2]. Actually, the lack of infrastructure in MANET nominates this kind of networks for using wherever the implementation of network infrastructure is impossible or too expensive such as military usages, emergency applications, PDA networking, and usual applications such as wireless meeting or classroom.

MANET uses routing protocols to route packets to destination like the conventional wired networks which are divided into PRP (Proactive Routing Protocol) and RRP (Reactive Routing Protocol) [3, 4]. Proactive Routing Protocols is called Table Driven Routing Protocol too. In PRP the routing information of all nodes are stored by the others, and routing updates are propagated whenever the topology of the network changes [5]. Another side, in the case of RRP, route

between the nodes is searched only whenever a source node wants to communicate with the others; they use Flooding method to discover the route by sending route request message which will be replied by the purposed destination. But the method of on-demand routing to facilitate route discovery may be used by the Intruders or the malicious node to consume the network resources, leading to Flooding attack [6, 7].

The remaining of this chapter is organized as follows; the second section will be discussed problem background, subsequently, problem statement will be described; the rest of the chapter is allocated for the objectivity of the project and its scope; finally, significant of the project and references are cited.

1.2 Problem background

According to properties of MANET, especially the lack of network infrastructure such as centralized administration, every node consists of many sorts of attacks; mostly, denial of service attacks. Although, using RRP (On demand Routing Protocols) have irrefutable benefits for mobile ad hoc network, however, they increases the risk of DoS attacks.

Actually, like conventional wired networks, MANET uses routing protocols to forward packets to the destination; Proactive routing protocols also, known as table-driven protocols is based on routing table between nodes. However, the main advantage of Proactive routing protocols can be declared as predictability of the control over head on these protocols; since it has a fixed upper bound which enables it to be independent to the traffic profiles [22]. In contrary, as disadvantages, we can state that they are not scalable perfectly and maintenance of routing table requires substantial network resources [20]. On the other hand, Reactive routing protocols or on-demand routing protocols are developed for MANET to direct packets to the destination. In fact they indicate the real basis of MANET which provides more

dynamic networks in comparison with structured ones. In the on demand routing protocols, nodes search for a route when they want to communicate with each other. To discover the routes they use route discovery procedure which in turns uses the Flooding method. Therefore, updating of the routing information is presented whenever a node requires a route instead of periodically updating the route information. Consequently, the control overhead will be reduced, especially in high mobility networks where the periodical update causes significant waste overhead [22]. However, on demand, routing protocols are categorized into secured on demand routing protocols such as SAODV [29], SEAD [32], SRP [21], ARAN [2], and Adriane [30]. And non-secure on demand routing protocols such as AODV [11] and DSR [23]. According to the studies, AODV is one of the most popular routing protocols for implementing additional DoS Attack detection modules because of its dynamic structure and perfect performance [12, 13].

In fact, MANET Flooding Attack is known as a harmful DoS attack which affects on functionality of almost all RRP's sharply. Mobile Ad hoc Flooding attack makes it possible for an adversary to carry out DoS by saturating the support with a quantity of broadcasting messages, by reducing the output of nodes, and in the worst case, to prevent them from communicating. In fact, there is similar attack in conventional wired networks which is popularly called SYN Flooding attack. In this attack, the attacker sends many TCP connection requests with spoofed source addresses to a victim. As a result, the resources of the victim host will be exhausted; subsequently, no more incoming TCP connection can be established by this machine [8].

Before describing Flooding Attack in MANET, it seems necessary to describe more about on-demand protocols especially AODV [11] which this project is relied on. AODV is one of the on-demand routing protocols, designed for MANET to manage unicast, multicast, and broadcast announcement. Actually, AODV is developed by using some principles of DSR [23] and DSDV [24] which are route discovery and route preservation from DSR and hop by hop steering sequence number and sporadic beacons from DSDV, respectively.

Actually, Flooding attack in MANET is categorized to two types which are Route Request (RREQ) Flooding attack and Data Flooding attack [8]. In RREQ Flooding attack the attacker broadcasts many route requests without consider to Rate-Limit, roundtrip-time, and Back-off-time. On the other hand, Data Flooding Attack occurs when an attacker creates a communication path with a victim node; and in the next step sends a huge amount of useless data packets to it to exhaust recourses of all intermediate nodes and waste bandwidth of the network. Because of the authentication methods implemented in on-demand protocols, the intermediate nodes cannot understand the contents of the packets, but they can just forward them to the destination; therefore, no one can detect data Flooding attack except the application layer of destination node [8].

Many valued efforts for sure have been tried to mitigate Flooding attack in MANET by using vary approaches such as FAP [8], AMTT [14], Filtering scheme [9, 10], and Trust scheme; but consequently, it seems that none of the mentioned mechanisms could solve Flooding attack in MANET totally. In fact, each of them has its specific limitations to solve both types Flooding Attack which will be described comprehensively in the rest of this article. However, this project proposes an alternative trust based scheme which is combination of related solution's strength and it is relied on cooperation between friend nodes. The main idea of this approach is coming from a friendship based framework [44, 45]; in the proposed scheme, we try to collect trust values from two ways as direct trust estimation and indirect trust value (Recommended trust) which are coming from friend neighboring nodes with a coefficient value that indicates their efficiency level in the decisions.

1.3 Problem statement

Although, Flooding Attack does not use any complex process to flood network, but the secured routing protocols cannot detect this attack naturally. This research tries to use a trust based mechanism to response route request Flooding Attack in MANET according to neighbor suppression approach. Moreover,

cooperative mechanism to collect information about suspicious nodes can restrict them for long term in the virtual societies greatly; then the problem of stranger nodes in high mobility situations can be solved too. Furthermore, this cooperation is based on both direct and indirect trust evaluation approach which is introduced as a suitable approach for distributed networks such as MANET or WSN [38]. This research will try to show that cooperation of friend nodes can develop a trusted set of nodes which can help to each other to make the best decision about a suspicious node and limiting its capabilities to Flooding area by using both direct trust calculating and recommended (indirect) trust computing simultaneously.

1.4 Aim of the project

This project tries to detect MANET Flooding attack by proposing a trust based mechanism as an alternative solution and also response side effects of this internal misbehavior.

1.5 Objectives of the project

In order to mentioned aims of the project, the objectives of the project related to flooding problem in MANET are stated as below:

- To analyze existing problems and solutions in MANET, related to Flooding attacks.
- To design alternative solution for MANET Flooding attack problem by using trust based mechanisms.
- To evaluate trust based Flooding Attack detection and response mechanisms for Ad hoc On-demand Distance Vector routing protocol.

1.6 Scope of project

The scope of this project is defined as following:

- Evaluations will be conducted only in simulation.
- Trust based Flooding Attack detection and response mechanisms will be compared with the original AODV routing protocol.

1.7 Significance of the study

The outcome of the project is to detect route request Flooding attack by using an enterprise trust based mechanism which controls active nodes of MANET to detect and response Flooding Attack. Actually, this method works as a friendship system to identify suspicious senders for long term and decrease the side effects of their attacks by monitoring their propagation. This project aims at introducing an alternative trust based mechanism to record background activities of vicious nodes and setup a plural opinion system for recognizing strangers in high mobility situation.
