Thesis submitted in fulfillment of the requirements
for the degree of
Master of Science

JANUARY 2011

ACKNOWLEDGEMENTS

Alhamdulillah, praised to Allah S.W.T. This dissertation would never have been completed without His guidance. I would very remiss if I do not thank the many people who helped me survive the birthing of this dissertation.

First of all, I would like to express my gratitude and appreciation to my main project Supervisor, Associate Professor Dr. Rokiah Hashim and Co-Supervisors, Associate Professor Dr. Othman Sulaiman, Dr. Fumio Kawamura, and Dr. Tay Guan Seng who have guided me throughout the research. Their endless support and encouragement in the present study are much appreciated. I would like to thank to all lecturers of Bio-resource, Paper and Coatings Division (BPC), Dean Professor Dr. Rozman Hj. Din, Head of BPC division Dr. Mazlan Ibrahim, Professor Dr. Abdul Khalil H. P. Shawkataly, Professor Dr. Wan Rosli Wan Daud, Associate Professor Dr. Baharin Azahari, Associate Professor Dr. Poh Beng Teik, Dr. Issam Ahmed Mohammed, Dr. Leh Cheu Peng, and Dr. Arniza Ghazali.

I would like to thank Universiti Sains Malaysia for granting me Graduate Assistant Scheme as financial support. Grateful thanks are expressed to technical staff of Bio-resource, Paper and Coatings Technology Division, Encik Farim Mohassan, Encik Azli Sufryzal Bunizar, Puan Noorhasni Othman, Encik Ahmad Yahya, Puan Noraida Bukhari, Encik Azhar Mohamad Noor, Encik Abu Mangsor Mat Sari and Encik Shamsul Zoolkifli for their technical support.

I want to express my special thanks to visiting scientists, Professor Masatoshi Sato and Miss Motoe Ando from Graduate School of Agricultural and Life Sciences, The University of Tokyo for sharing ideas and lots of important information.

To all my beloved colleagues, my juniors and also to all my seniors thank you so much for accompanying, helping and guiding me in reaching the final stage.

I dedicated this dissertation to my beloved, dearest parents, Wan Nadhari Wan Ahmad and Azizah Man whose prayers, support and love blessed my heart and sustained me in the years of life. My siblings, Wan Noor Tutiana Wan Nadhari, Wan Shahrizal Wan Nadhari, Wan Shahfaizal Wan Nadhari, Wan Noor Suzana Wan Nadhari, Wan Noor Azleen Wan Nadhari, and Wan Noor Farahana Wan Nadhari. Their love, care, patient and support were tremendous and endless and also those who have contributed in various ways.

Thank you.

Regards,

WAN NOOR AIDAWATI BINTI WAN NADHARI

**KAJIAN KE ATAS SIFAT-SIFAT PAPAN SERPAI TANPA
PENGIKAT DARIPADA BIOMAS KELAPA SAWIT (*Elaeis
guineensis*)**

ABSTRAK

Papan serpai tanpa pengikat telah dihasilkan daripada partikel-partikel kulit, daun, pelepah, bahagian tengah dan teras batang kelapa sawit pada dua perbezaan ketumpatan sasaran iaitu 0.8 g/cm³ dan 1.0 g/cm³ dan dua tekanan yang berbeza iaitu 5 MPa dan 12 MPa. Ujian fizikal dan mekanikal telah dijalankan ke atas papan serpai tersebut. Sebahagian analisis kimia juga telah dijalankan seperti penentuan ekstraktif, holoselulosa, alfa-selulosa, lignin, kandungan kanji, gula individu, dan jumlah gula yang hadir dalam bahan-bahan tersebut. Pencirian spektroskopi juga dilakukan dengan menggunakan Spektrofotometer Inframerah Transformasi Fourier (FT-IR) untuk mengkaji kewujudan kumpulan berfungsi yang terdapat di dalam gentian kelapa sawit sebelum dan selepas panel dihasilkan. Pemerhatian anatomi bahan mentah dan panel diperhatikan dengan menggunakan Mikroskop Elektron Pengimbas (FESEM). Keputusan menunjukkan panel yang diperbuat daripada teras batang kelapa sawit mempunyai nilai kekuatan modulus kepecahan (MOR) dan kekuatan ikatan dalaman (IB) yang paling tinggi, pengembangan ketebalan (TS) dan penyerapan air (WA) yang paling rendah berbanding dengan semua sampel yang lain. Sebahagian daripada panel yang dihasilkan telah memenuhi *Japanese Industrial Standards (JIS A- 5908)* untuk *Type 8, Type 13* dan *Type 18*. Walau bagaimanapun, panel yang diperbuat daripada kulit batang dan daun kelapa sawit tidak mempunyai kekuatan dan kestabilan dimensi yang memuaskan.

Berdasarkan keputusan yang diperolehi, biomas kelapa sawit dapat dipertimbangkan sebagai bahan mentah alternatif mesra alam untuk menghasilkan panel papan serpai tanpa pengikat.

STUDY ON PROPERTIES OF BINDERLESS PARTICLEBOARD FROM OIL PALM (*Elaeis guineensis*) BIOMASS

ABSTRACT

Binderless panels were manufactured from the particles of bark, leaves, fronds, middle-part and core-part of oil palm trunks at two different target densities (0.8 g/cm³ and 1.0 g/cm³) using two different pressures (5 MPa and 12 MPa). Binderless panels produced were tested for the physical and mechanical properties. Chemical analysis had also been conducted including determination of extractives, holocellulose, alpha-cellulose, lignin content, starch content, individual sugar, and total sugar content in oil palm fibers. Spectroscopic characterization was done using Fourier Transform Infrared (FT-IR) spectroscopy to detect the presence of the functional group that exists in oil palm fibres before and after the board was made. The anatomical features of the raw materials and the manufactured panels were viewed using Field Emission Scanning Electron Microscopy (FESEM). The results showed that panels produced from core portion of the trunks exhibited the highest Modulus of Rupture (MOR) and internal bond (IB) strength, but lowest thickness swelling (TS) and water absorption (WA) values among the samples. Some of the tested panels had met Japanese Industrial Standards (JIS A- 5908) for the Type 8, Type 13 and Type 18. However, panels made from bark and leaves did not have satisfactory strength and dimensional stability. Based on the results of this study, oil palm biomass could be considered as environmentally friendly alternative raw material for the manufacture of binderless particleboard.

CHAPTER ONE: INTRODUCTION

1.0 Background of the study

Malaysia is one of the world's largest producers and exporters of palm oil. The production of palm oil is reflecting on many sides as economic, environmental and social benefits. Solid wastes and oil palm by parts available in huge amount all over the year. Oil palm biomass of trunk, fronds, empty fruit bunches, fiber, shell and waste matter would be obtained during assiduous life of the palm covering about 25 years. The oil palm biomass such as oil palm trunks produced during felling of old trees were normally shredded and left in the field to decompose naturally (Khozirah et al., 1991; Mohamad et al., 1985). Previously, some estate burn these waste in the field for fast disposal. This will produce more carbon dioxide emission to the environment. The utilization of oil palm biomass to produce a value added product can reduce the effect of the activity in decomposing the waste due to environmental concern. Furthermore utilization of this waste will reduce the consumption of wood as raw material.

Particleboard is one of the extensively used wood based panels to manufacture building elements such as furniture components for interior purposes. The use of agricultural resources such as empty fruit bunch (EFB), kenaf, padi stalks, jute, flax, reed, cotton, grapevine, bagasse, straw, rice husks and bamboo have been used to make particleboards. As known, synthetic adhesive is required to manufacture a wood panel product. In particleboard manufacturing, adhesive is generally accepted to be the most costly raw material for making particleboard. Even though it is used only 8 % to 10 % of the weight of oven dries of the raw material, it still contributes 60 % to the overall cost of final product (Hashim et al., 2005; Laemsak & Okuma, 2000). Moreover, there are some harmful side effects such as health risks caused by the emission of volatile

organic compounds from the adhesives. Many consumer products containing formaldehyde based resins release formaldehyde vapour, leading to consumer dissatisfaction and health related complaints. Therefore, manufacturing particleboard without any adhesive would provide an alternative to those with synthetic adhesive. The strategy of high income and zero waste are the goals towards sustainability because producing products such as binderless particleboard from oil palm biomass will benefit society, being environmentally friendly, recyclable, renewable and biodegradable.

1.1 Problem statement

Nowadays, there are global concerns for new energy resources from biomass. Huge amounts of oil palm biomass are being left unexploited in oil palm plantation. There were less old felled trunks and other oil palm biomasses been utilized and most of them have no convenient way of utilization and become troublesome wastes. In addition, the cost of particleboard manufacturing is high due to the use of adhesives because adhesive is one of the most costly raw materials for making particleboard (Laemsak & Okuma, 1999). Besides, emission of formaldehyde can cause health hazards contributed by formaldehyde based adhesives especially in particleboard manufacturing. Thus, in this research, a study on properties of binderless particleboards made from different types of oil palm biomass was being carried out.

1.2 Objectives

The main objective of this study is to produce binderless particleboard from different types of oil palm biomass.

The specific objectives are as follows:

- a) to study and compare the physical and mechanical properties of binderless particleboard made from different types of oil palm biomass.
- b) to compare the performance of binderless particleboard with the phenol formaldehyde particleboard, in accordance to JIS standard for particleboard Type 8, Type 13 and Type 18.

CHAPTER TWO: LITERATURE REVIEW

2.0 Oil palm industry in Malaysia

The oil palm in Malaysia is more than a century old. Oil palm (*Elaeis guineensis* Jacq) becomes better known crop, especially in Southeast Asia, than in its origin country, West Africa (Basiron & Chan, 2000). Currently, Malaysia and Indonesia are the main producers and supplying more than 85% of world oil consumption (Table 2.1). The table illustrates the world major producers of palm oil from 1999 to 2008. The producer countries have been facing a stern environmental problems concerning solid biowaste handling of oil palm industry. In the year of 1999, Malaysia produced about 10 554 000 tonnes of palm oil. The values had increased up to 17 734 000 tonnes in 2008, showing an increase of 68 % in the period of nine years.

In 2008, Malaysia was the world's major exporter of palm oil with 15.41 million tonnes or 45.84 % of the total world's exporters (Table 2.2). In Malaysia, palm oil has reached extraordinary growth in production and exports in the last few decades. Concurrence to Oil World Annual Statistics 2008, over the last decade between 1990-2008, the main palm oil producing countries have steadily increased their production. By the end of 2008, the major exporters of palm oil (in '000 tonnes), were Malaysia (15.41), Indonesia (14.47), Papua New Guinea (0.40), Columbia (0.33), and many other countries with smaller oil palm areas.

2.0.1 Oil palm planted area in Malaysia

The oil palm was commercially exploited as an oil crop only from 1911 when the first oil palm estate was established in 1917 (Basiron et al., 2000). The expansion of the palm oil industry, in terms of planted area has been very speedy from 1975 until 2009 as seen in Table 2.3 and Table 2.4. In 2009, the total area planted with oil palm was 4.69 million, 53.1% or 2.49 million hectares being in Peninsular Malaysia, 29% or 1.36 million hectares in Sabah and 17.9% or 4.69 million hectares in Sarawak. The last decade had seen a quick extension in the cultivated area in Sabah and Sarawak while planting in Peninsular Malaysia had slowed down because of diminishing availability of new land for the crop.

Table 2.3: Oil palm planted area: 1975-1991 (Hectares)

Year	P.Malaysia	Sabah	Sarawak	Total

2.0.2 Botanical classification of oil palm

Elaeis guineensis Jacq. which is universally known as the oil palm is the most vital species in the genus *Elaeis*. According to Taxonomic Information System, (2009) the oil palm taxonomy is shown below:

Kingdom	: Plantae
Sub-Kingdom	: Tracheobionta
Division	: Angiospermae
Class	: Monocotyledons
Sub-Class	: Arecidae
Order	: Arecales
Family	: Arecaceae
Genus	: <i>Elaeis</i>
Species	: <i>Elaeis guineensis</i> Jacq
Common name	: African oil palm

2.0.3 Oil palm biomass

Biomass can be defined as any organic plant product that has general uses. Lignocellulosics have been included in the term biomass. Therefore, oil palm biomass; the palm kernel, trunks, fronds, leaves, empty fruit bunches, pressed fruit fibers and shells consist of cellulosic fibers. Oil palm contains lignocellulosics material (Akmar & Kennedy 2001) which could be ideal for producing value-added composite panels and oil palm is one of the most versatile crops where nearly every part of the palm, from oil to the entire biomass can be utilized. Table 2.5 shows the wet weight of oil palm biomass available in Malaysia. The amount of oil palm biomass (wet weight) available annually is estimated to be from OPT: 13.93 million tonnes or 21.63 million cubic meters from replanting; and OPF, 75.90 million tonnes from the field.

Table 2.5: The wet weight of oil palm biomass available in Malaysia

Sources of oil palm biomass	Unit	
	Million tonnes per year (wet weight)	Million cubic meter (per year)
Peninsular Malaysia		
Oil Palm Trunk (OPT)	7.91	12.29
Oil Palm Frond (OPF)	43.12	
Empty Fruit Bunch (EFB)	9.69	
Sabah and Sarawak		
Oil Palm Trunk (OPT)	6.01	9.34
Oil Palm Frond (OPF)	32.78	
Empty Fruit Bunch (EFB)	6.36	
Total	105.87	21.63

(Source: Anis et al., 2008)

The oil palm biomass supply outlooks in Malaysia from 1996 to 2020 (t/yr, dry weight) is shown in Table 2.6. In future, total amount of the whole trunk in 2017-2020 will be estimated up to 2 971 934 t/yr, dry weight and total amount of leaf stalks and petiole (fronds) will be 13 643 185 and 7 141 490 t/yr, dry weight (Table 2.6). As the oil palm biomass consists of lignocellulosic material, it is a valuable raw material for value added products.

2.0.4 Oil palm trunk

2.0.4.1 Anatomical review of oil palm trunk

Oil palm is monocotyledonous species that does not have cambium, secondary growth, ray cells, annual or growth rings, sapwood and heartwood or branches and knots (Killman & Lim, 1985). The growth and increase in diameter of the trunk outcome from the overall cell division and cell enlargement in the parenchymatous ground tissue, together with the growth of the fibers of the vascular bundles (Khozirah et al., 1991). There are three main parts, namely cortex, peripheral region based and central region based on a cross sectional view of the oil palm trunk (Killman & Lim, 1985).

2.0.4.2 Cortex, periphery and central region

Cortex is approximately 1.5 to 3.5 cm wide, makes up the outer part of the trunk. It is largely composed of ground parenchyma with abundant longitudinal fibrous strands of small and irregular shaped fibrous strands and vascular bundles (Killman & Choon, 2001) as shown in Figure 2.1. Periphery area with slender layers of parenchyma is crowded with vascular bundles. It provides the main mechanical support for the palm trunk (Killman & Choon, 2001). The central region is composed of slightly larger and widely spotted vascular bundles embedded in the thin wall parenchymatous ground tissues. The bundles increase in size and are more widely spotted towards the core of the trunk (Killman & Choon, 2001).

Figure 2.1: Cross section of an oil palm stem division into various anatomical parts.

(Source: Killman & Lim, 1985)

2.0.4.3 Vascular bundles and parenchymatous tissue

The number of vascular bundles per unit area decrease towards the inner zones and increase from the butt end to the top of the palm (Killman & Lim, 1985). Each vascular bundle is mainly made up of a fibrous sheath, phloem cells, xylem and parenchyma cells (Figure 2.2). According to Lim & Khoo (1986) the xylem is sheathed by parenchyma and contains mainly one or two wide vessels in the peripheral region and two or three vessels of similar width in the central and inner region. Lim & Khoo (1986) also further stated that the distribution of fibrous strands depends on the number of bundles nearby. The ground parenchymatous cells consist mainly of thin-walled spherical cells, except in the area around the vascular bundles. The walls are progressively thicker and darker from the inner to the outer region (Killman & Lim,

1985; Basiron et al., 2001). The distribution of vascular bundles in the inner zone of the oil palm trunk varies depending on the palm. The fibers usually have a well developed secondary wall with a typically multilayered appearance. The trunk is primary tissue and is not compare in developmental terms to the wood of dicotyledons and gymnosperms. Vascular bundles in oil palm trunk range from about 1 to 3 mm in diameter depending on their location within the stem and the species (Parthasarathy & Klotz, 1976).

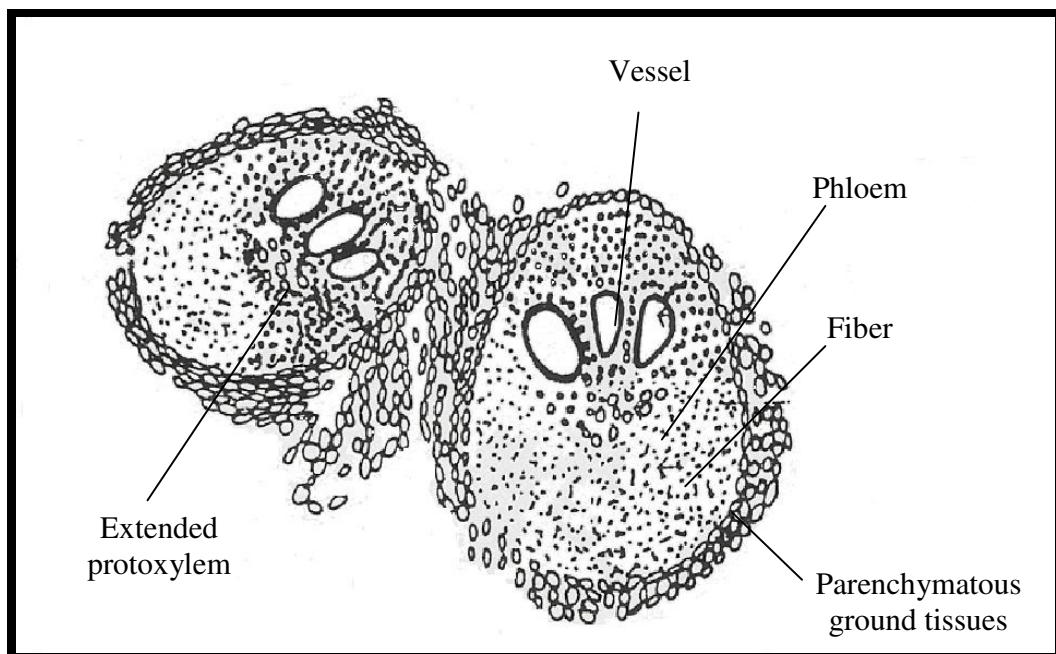

Figure 2.2: Fiber
(Source: Killman & Lim, 1985)

2.0.4.4 Physical properties of oil palm trunk

2.0.4.4.1 Moisture content

The initial moisture content of the oil palm trunk varies from 100 and 500% (Killmann & Lim, 1985). In the other study, oil palm trunks contain very high moisture content from 60-300% depending on the height and age of the trunk (Singh, 1994 and Mohammad 2000). A gradual increase in moisture content is indicated along the trunk height and towards the central region, with the outer and lower zone having far lower values than the other two zones. Based on depth of the trunk, the highest moisture content was reached at the central of trunk and a gradual decrease to the outer part of trunk while based on the trunk height factor, the moisture content was decreased from the bottom to the top of the oil palm tree (Lim & Khoo, 1986).

2.0.4.4.2 Density

Density values of the oil palm trunk range from 200 to 600 kg/m³ with an average density of 370 kg/m³. There is a variation of density values at different parts of the oil palm trunk consequently of its monocotyledonous nature. The density of oil palm trunk decreases linearly with the trunk height and towards the centre of the trunk and the outer region throughout the trunk shows density values over twice those of the inner areas (Lim & Khoo, 1986). Across the trunk the density is influenced largely by the number of vascular bundles per square unit which decreases towards the center. However, variations in density along trunk height are due to the vascular bundles being younger at the top and of the palm (Killmann et al., 1985; Husin et al., 1985).

2.0.4.4.3 Fiber dimensions

The palm development in trunk diameter caused by the widen of the fibrous bundle sheath, mostly those complementary the vascular bundles in the central region and the oil palm fiber length enlarges from periphery to the inner part. The fiber diameter decreases along trunk height because broader fibers are to be found in the larger vascular bundles nearer the base of the palm trunk (Lim & Khoo 1986). The fiber dimensions of oil palm trunk, fronds, rubberwood and douglas fir are shown in Table 2.7.

Table 2.7: Comparison of fiber dimension between oil palm trunk, fronds, EFB, rubberwood and douglas fir.

Dimension	Trunk	Fronds	EFB	Rubberwood	D/Fir
Fiber length (mm)	1.22	1.52	0.89	1.50	3.4
Fiber diameter (μ)	35.3	*19.4	25.0	40.0	40.0
Cell wall thickness	4.5	*4.6	2.8	5.3	**na

(Source: Mohamad et al., 1985)

* Liew, 1996

**na: not available

2.0.5 Oil palm fronds

The oil palm fronds are available during felling operations and during fruit harvesting. These are potential sources of fibers and are now used in the production of building materials, panel products, and for pulp and paper (Salleh et al., 2007). The fronds are also used as mulch in the field (Mohamad et al., 1985). In the process of replanting, pruned fronds are available in the field. The requirement of oil palm fronds for value-added is now had been competitive. While petiole is harvested, the rachis and leaflets are left behind (Mohamad et al., 1995 and Gurmit et al., 1999).

2.0.6 Oil palm leaves

The oil palm leaves are also available seasonally during felling operations. The oil palm leaf consists of leaflets, each with a lamina and midrib, a central rachis, to which the leaflets are attached, a petiole (the part of the leaf stalk between the lowest leaflets and the trunk), and a leaf sheath. The total number of leaves on a plantation palm depends largely on the harvesting and pruning methods in use. The oil palm single vegetative growing point is situated in a depression at the stem apex, as with other large palms. This meristem is continuously active, producing a new leaf primordium about every two weeks in a mature palm and the leaf takes about two years to develop from initiation to the time the leaflets unfold in the centre of the palm crown, and may then spend a further two years actively photosynthesizing, before senescence sets in (Corley, et al., 1982).

The leaf is pinnate, with the pinnae (leaflets) arranged in two or more planes on each side of the rachis. Leaf size increases progressively up to about eight or ten years after planting, when it reaches a maximum which is maintained for at least ten years and probably much longer (Corley, et al., 1982).

2.0.7 Chemical properties of oil palm biomass

The main constituent in oil palm fibers is cellulose. Oil palm trunk (OPT) fiber exhibited the highest content of extractives and lignin compared to empty fruit bunch (EFB), oil palm frond (OPF), hardwood and softwood (Abdul Khalil et al., 2008). The quantity of cellulose in fibers influences the property and economic production of fibers for different uses. Chemical composition varies from plant to plant and within plants from different parts of the same plant. It also varies between plants from different geographic locations, ages, climate and soil conditions (Rowell et al., 2000). The chemical compositions of oil palm biomass are presented in Table 2.8 together with the previously mentioned species as comparison.

Table 2.8: Chemical composition of oil palm biomass and wood fibers

	Extractives (%)	Holocellulose (%)	Alpha-cellulose (%)	Lignin (%)	Ash (%)
Oil palm trunk	- 5.35**	45.70* 73.06**	29.20* 41.02**	18.80* 24.51**	2.30* 2.20**
Oil palm frond	- 4.40**	80.50* 83.54**	- 56.03**	18.30* 20.48**	2.50* 2.40**

Source:

*Mohamad et al., 1985

**Abdul Khalil et al., 2008

***Tsoumis, 1991

In general, oil palm has low lignin and holocellulose content as compared to hardwood, softwood and rubberwood (Table 2.8). The lignin content in oil palm range varies between 17 % and 25 %. Besides, Halimahton and Ahmad, (1990) observed that the lignin content was fairly evenly distributed throughout the tree except that the core in the upper region was slightly lacking in the component even as the bottom contained an extreme amount. The ash content also observed to be similar throughout the oil palm with the range varies between 2.2 % and 3.5 %.

2.0.7.1 Cellulose

Cellulose is a linear polymer of D-glucopyranose sugar units (the dimer, cellobiose) linked in a beta configuration and the average cellulose chain has a degree of polymerization of about 9,000 to 10,000 units (Rowell, 2005). Besides, approximately 65 percent of the cellulose is highly oriented, crystalline, and not accessible to water or other solvents. The strongest component of the lignocellulosic resource is the cellulose polymer. The remaining cellulose, composed of less oriented chains, is only partially accessible to water and other solvents as a result of its association with hemicellulose and lignin. None of the cellulose is in direct contact with the lignin in the cell wall (Tsoumis, 1991; Sjostrom 1993).

2.0.7.2 Hemicellulose

The hemicelluloses are a group of polysaccharide polymers containing the pentose sugars D-xylose and L-arabinose and the hexose sugars D-glucose, D-galactose, D-mannose, and 4-O-methylglucuronic acid (Tsoumis, 1991). Hemicellulose is amorphous and highly branched with a much lower degree of polymerization than cellulose. Hemicellulose varies in structure and sugar composition depending on the source (Reddy & Yang, 2005). Hemicellulose is soluble in alkali and is easily hydrolyzed by acids (Rowell, 2005).

2.0.7.3 Lignin, extractives and ash content

Lignin is amorphous, highly complex, and aromatic polymers of phenylpropane units (Sjostrom, 1993). Lignin does not have a single repeating unit of the hemicelluloses like cellulose, but consists of a complex arrangement of substituted phenolic units. Lignins are composed of nine carbon units derived from substituted cinnamyl alcohol; coumaryl, coniferyl, and syringyl alcohols that are highly branched, not crystalline, and their structure and chemical composition is a function of their source (Donaldson, 2001; Reddy & Yang, 2005). The molecular weight of lignin depends on the method of extraction. Klason lignin, because it is highly condensed, has molecular weights as low as 260 and as high as 50 million (Goring, 1962).

The extractives are a group of cell wall chemicals mainly consisting of fats, fatty acids, fatty alcohols, phenols, terpenes, steroids, resin acids, rosin, waxes, and many other minor organic compounds (Rowell, 2005). These chemicals exist as monomers, dimers and polymers. Extractives are responsible for the colour, smell and durability of the wood. The qualitative difference in extractive content from species to species is the basis of chemotaxonomy (taxonomy based on chemical constituents). The extractive materials are primarily composed of cyclic hydrocarbons. The remaining mass of lignocellulosics consists of water, organic soluble extractives, and inorganic materials. These vary in structure depending on the source and play a major role in natural decay and insect resistance and combustion properties of lignocellulosics (Mukherjee, 1972).

Ash content is the inorganic portion can vary from a few percent to over 15 percent, depending on the source. Ash content may be high for plant which has higher amount of silica (Rowell, 2005).

2.1 Particleboard

2.1.1 General

Particleboard is a composite material and product manufactured from wood particles, flakes, sawdust, or sawmill shavings using suitable binder or synthetic adhesive which is pressed together (Abdul Khalil & Hashim, 2004). It is produced by mechanically reducing the material into small particles, drying, screening, mixing with adhesives and additives, forming, consolidating a loose mat of the particles with heat and pressure into a panel product and finishing. The first industrial production of particleboard using synthetic resins is believed to have occurred in 1941 in Bremen, Germany using phenolic binders and spruce particles (Moslemi, 1973). Various size of wood particles were glued together to produce particleboard (Rowell, 2005). According to Moslemi, (1973) particleboard is cheaper, denser and more uniform than conventional wood and plywood. The properties of the board can be engineered to meet specific requirements such as sufficient bending strength and dimensional stability, flat and smooth surfaces and good machining characteristics. Dimensional stability of particleboard varies depending on the amount and type of adhesives and internal bond of particleboard (Rowell, 2005).

2.1.2 Raw materials of particleboard

The main components in particleboard are wood particle and adhesive. Soft wood and medium density hard wood are the common type of wood used to produce particleboard. Adhesive level usually is around 5 – 15% based on oven dry weight of the board. Urea formaldehyde and phenol formaldehyde is the common adhesive used in manufacturing particleboard (Rowell, 1992). At present, particleboards are manufactured from residues of non-commercial and low-grade timbers generated by the wood-based mills. The demand for rubberwood as sawn timber, furniture and other composites products has been increasing in the last ten years resulting in a price increase of rubberwood. Due to the increasing cost of rubberwood, the particleboard industry in Malaysia is looking into alternative supply of raw materials. The oil palm biomass seems to be potential raw materials in particleboard industry in Malaysia. The plentiful lignocellulosic residues are existing from the palm oil mills and plantations. This alternative raw material could be expected to ease the dependence on the forest.

2.1.3 Particle preparation and blending

Debarking process of log is the first step before being fed into disk chipper or flake machine (Chew, 1987). Then, the log is fed into disk chipper to be reduced to particle. Size particle varies and depends on manufacture. After chipping process, the particles are screened out and oversized particles are fed to the chipper again. Particles with required size will be dried up before it is used to produce particleboard. Particle is required to dry to uniform moisture content and the type of adhesive used depends on end use of the product (Moslemi, 1973).

2.1.4 Mat forming and pressing

The particles mixture is made into a mat after the adhesive has been mixed with the particles. The particles were spread by an air jet or extruder which throws finer particles further than coarse ones. The sheets formed were then cold compressed to reduce their thickness and sent to the hot press. Boards were compressed again, under pressures and temperatures between 140 to 220 °C (Moslemi, 1973). All aspects of this entire process were carefully controlled to ensure the accuracy of size, density and consistency of the board.

2.1.5 Properties and application of particleboard

The properties of particleboard depend on many factors including the type and size of particles, techniques of manufacture, type and amount of resin, particle distribution and orientation, board density, quality of manufacture (effectiveness of resin spread and forming), furnish moisture content, and post manufacturing treatments (Moslemi, 1973). Particleboard bonded using melamine formaldehyde and phenol formaldehyde was reported to have better dimensional stability than urea formaldehyde (Moslemi, 1973). Higher board densities are related with higher strengths, more difficult machining characteristics, a greater degree of dimensional instability, and higher cost per unit volume. Low density board offers better insulating characteristics, higher dimensional stability, lower strength, and less unit cost. The direct influence of density over product weight is basic importance in many applications (Chew, 1987). Particleboard with low density was less than 0.6g/cm^3 , medium density between $0.6\text{ g/cm}^3 - 0.8\text{ g/cm}^3$ and high density with more than 0.8 g/cm^3 .

The applications of particleboard are commonly used as core material for furniture panels, flush doors, veneer wall panels, desk tops, drawer fronts, chest and table tops, dust dividers, shelves, chest sides, sewing machine cabinets, bed rails, headboards, bookcase sides, backs and shelves, interior ceilings and walls, components for interior millwork such as kitchen cabinets, wardrobe, flooring and other storage compartments (Carll, 1986).

2.1.6 Formaldehyde emissions

Formaldehyde is an important precursor for the preparation of urea, melamine and phenol formaldehyde resins which are used as binders in the wood based panel manufacturing. It is very reactive chemical and goes through a series of technically significant reactions. Formaldehyde release is highly unwanted because it causes assorted uneasiness including itchy and watery eyes. Formaldehyde release continuously sticks with at a high level for a long period of time after the product has begun service in the particular application (Roffael, 1993).

The past decade ago, publicity has come up about formaldehyde vapor contaminating air in dwelling. This infectivity can come from many sources, including tobacco smoke, urea formaldehyde foam insulation, carpeting, soft goods furnishings, particleboard and decorative plywood (Carll, 1986). Hydrolysis of the cured urea formaldehyde occurs in such an environment, and results in release of formaldehyde vapors and loss of the board strength. Carll (1986) further stated that hydrolysis can theoretically continue indefinitely if humidity and temperature remain at high levels.
