Specific group of controlled drug delivery systems in bone tissue engineering are multifunctional nanoparticle systems (MNPs) based on hydroxyapatite coated with drug loaded-bioresorbable polymer. This study illustrates the possibility for controlled synthesis of multifunctional nanoparticulate forms based on hydroxyapatite as a system for local delivery of vitamin D3 and secondary delivery of defect filler hydroxyapatite. The results were two type of nanoparticle powder of controlled shapes, sizes and properties: hydroxyapatite nano particles as vitamin D3 carriers (HAp/D3) and vitamin D3-loaded hydroxyapatite coated with poly-D,L-lactide-co-glycolide (HAp/D3/PLGA) with particle sizes of d50=68 nm and d50=71 nm, respectively.

Simultaneously, biocompatibility of the materials was tested *in vitro*, on osteoblastic MC3T3-E1 and epithelial Caco-2 cells in culture. Biocompatibility tests carried out on cell cultures have shown intact monolayers of epithelial cells in contact with both materials and no negative effects on the cell viability.

The aim of this work was application in living/human systems, and it has been tested *in vivo*; artificially made bone defects of a mandible damaged by osteoporosis have been reconstructed with both types of materials. The best results were achieved 24 weeks after implantation of vitamin D3-loaded hydroxyapatite coated with poly-D,L-lactide-co-glycolide. Accelerated angiogenesis, vascularization, osteogenesis and bone structure differentiation has been achieved in the presence of specific islet-like forms of ossification centers.
