26 **Abstract**

27 Evaluation of the epitope specificities, location (systemic, mucosal) and effector function of
28 antibodies elicited by novel HIV-1 immunogens engineered to improve exposure of specific
29 epitopes is critical for HIV-1 vaccine development. Utilizing an array of humoral assays, we
30 evaluated the magnitude, epitope specificity, avidity and function of systemic and mucosal
31 immune responses elicited by a vaccine regimen containing Env cross-linked to a CD4 mimetic
32 miniprotein (gp140-M64U1) in rhesus macaques. Crosslinking of gp140 Env with M64U1
33 resulted in an earlier increase in both the magnitude and avidity of the IgG binding response
34 compared to Env protein alone. Notably, binding IgG responses at an early time point correlated
35 with Antibody Dependent Cellular Cytotoxicity (ADCC) function at the peak immunity time point,
36 which was higher for the crosslinked Env group compared to the Env group alone. In addition,
37 the crosslinked Env group developed higher IgG responses against a linear epitope in the C1
38 gp120 region of the HIV-1 envelope glycoprotein. These data demonstrate that structural
39 modification of the HIV-1 envelope immunogen by crosslinking gp140 with the CD4 mimetic
40 M64U1 elicited an earlier increase of binding antibody responses and altered the specificity of
41 the IgG responses that correlated with the rise of subsequent antibody-mediated antiviral
42 functions.

43

44 **Importance**

45 The development of an efficacious HIV-1 vaccine remains a global priority to prevent new cases
46 of HIV-1 infection. Of the six HIV-1 efficacy trials to date, only one has demonstrated partial
47 efficacy, and the immune correlates analysis of this trial revealed a role for binding antibodies
48 and antibody Fc mediated effector functions. New HIV-1 envelope immunogens are being
49 engineered to selectively expose the most vulnerable and conserved sites on the HIV-1
50 envelope with the goal of eliciting antiviral antibodies. Evaluation of the humoral responses
51 elicited by these novel immunogen designs in nonhuman primates is critical for understanding

52 how to improve upon immunogen design to inform further testing in human clinical trials. Our
53 results demonstrate that Env structural modifications that aim to mimic the CD4 bound
54 conformation can result in earlier antibody elicitation, altered epitope specificity and increased
55 antiviral function post immunization.

56

57 **Introduction**

58 A critical component in the path toward the development of a successful HIV-1 vaccine
59 strategy is definition of the epitope specificities, location (systemic, mucosal) and effector
60 function of antibodies elicited by novel HIV-1 immunogens engineered to improve exposure of
61 specific epitopes. There is a growing body of evidence from animal models that antibodies can
62 control virus replication (1-4) through elimination of infected cells (4), engagement of Fc-
63 mediated antibody effector functions to limit founder viruses (2), and delay acquisition and/or
64 prevent the establishment of infection (5-15) through mechanisms including virus neutralization
65 (8-14, 16) and antibody Fc-mediated anti-viral functions (11, 15, 17). Together, these studies
66 include both passive immunization strategies and vaccine approaches that have tested a range
67 of antibody specificities, antibody isotypes and effector functions (broadly neutralizing, non-
68 broadly neutralizing and antibody Fc-mediated antiviral activities), thus demonstrating that there
69 is much diversity in the types of antibodies that may protect. However, there remains a gap in
70 understanding how different immunogen designs specifically impact antibody specificities,
71 kinetics and antiviral functions (*i.e.* neutralizing and non-broadly neutralizing).

72

73 There are numerous challenges for inducing broadly neutralizing antibody functions by
74 vaccination, including but not limited to shielding of key epitopes by glycans, difficulty in
75 presentation of the correct Env structures, and the unusual traits of broadly neutralizing
76 antibodies (18, 19). In contrast, the one partially efficacious HIV-1 vaccine in humans
77 demonstrated a potential role for non-broadly neutralizing antibodies in preventing HIV-1

78 acquisition (20). Non-broadly neutralizing antibodies include CD4-induced (CD4i) antibodies that
79 target epitopes whose exposure is triggered by binding of HIV-1 Env gp120 to CD4 on the host
80 cell. A recent study demonstrated that CD4i antibodies correlated with viremia control following
81 mucosal challenge in rhesus macaques (3).

82

83 HIV vaccine strategies can involve modifying the structure of Env for improved exposure
84 of CD4i epitopes. CD4i epitopes include co-receptor binding sites (21, 22) that are highly
85 conserved (23-25) as well as variable loop domains (26, 27), some of which are easily elicited
86 during natural HIV-1 infection (24, 28, 29). One immunogen design approach has utilized co-
87 expression of CD4 in a single molecular structure with HIV-1 Env to promote binding and
88 complex formation of CD4 and Env (3, 30-34). Another approach involves small molecule CD4
89 mimetic compounds, which have been shown to inhibit HIV-1 virus entry by competitively
90 binding to CD4 binding site (CD4bs) (35, 36). A recent study further showed that CD4 mimetic
91 compounds can activate or inactivate primary HIV Env trimers depending on properties of the
92 CD4 mimetics and the Env trimer, and how many subunits of the trimer are bound (37). Several
93 studies have explored biochemical cross-linking of synthetic CD4 mimetic molecules with Env
94 proteins for improved CD4i epitope exposure (31, 38-41). In particular, a CD4-mimetic
95 miniprotein M64U1, has been shown to expose both CD4i epitopes and co-receptor binding
96 sites when covalently conjugated to Env gp140 (38), eliciting increased titers of CD4i antibody-
97 mediated neutralization in rabbit immunization studies (38, 42). The gp140-M64U1 cross-linked
98 vaccine was further tested in macaques (Bogers *et al*, submitted) and was shown to alter the
99 kinetics of B cell responses and levels of neutralization and ADCC responses. Here we further
100 characterized the magnitude, specificity, and kinetics of binding antibody responses and
101 examined the correlation between these parameters of binding antibody response with that of
102 antibody functions, providing novel evidence that the cross-linked gp140-M64U1 complex can

103 impact both the binding properties of and the antiviral functions mediated by Env-specific
104 antibodies in primates.

105

106 **MATERIALS AND METHODS**

107 **Animal study design.**

108 Rhesus macaques of Chinese origin were housed at the Biomedical Primate Research Center
109 (BPRC), The Netherlands. The study protocol and experimental procedures were approved by
110 the institute's animal ethical care and use committee and were performed in accordance with
111 Dutch law and International ethical and scientific standards and guidelines (Bogers *et al*,
112 submitted). The study consisted of four groups of 6 animals each (**Table 1**). One group (gp140
113 group) received intramuscular immunization with 100 mg gp140 protein with the variable loop 2
114 (V2) deleted (SF162ΔV2 gp140), administered in adjuvant MF59; the second group (gp140-
115 M64U1 group) received immunizations with 100 mg gp140 cross-linked with the CD4-mimetic
116 M64U1 (gp140-M64U1, produced by incubating gp140 with M64U1-SH that contains an
117 additional sulfhydryl group on the side chain of Lys4 at 1:3 gp140:M64U1-SH ratio) (38, 42),
118 also in MF59. In addition, two control groups received either the M64U1/MF59 only (50 mg) or
119 mock immunizations. All protein immunizations were delivered intramuscularly at week 0, 4, 24,
120 36, and 107 of study.

121 **Binding antibody multiplex assay (BAMA).**

122 Env-specific IgG and IgA responses in serum and in mucosal samples were measured as
123 previously described (29, 43, 44). For quantification of IgA responses, IgG was depleted from
124 sera using Protein G HP MultiTrap Filter Plates (GE Healthcare Life Sciences). Mucosal
125 specimens were filtered, buffer-exchanged, and concentrated to equal volumes before
126 measurement of total and specific antibody. The rectal wash samples were examined and none
127 had visual blood contamination. Total IgG concentration in each mucosal sample was
128 determined by macaque total IgG ELISA, and specific activity was calculated as: Specific

129 activity= (MFI x dilution)/total antibody. For characterization of CD4 binding site (CD4bs) and
130 CD4-inducible (CD4i) antibodies, a CD4bs and CD4i differential binding antigen panel was used
131 for BAMA, which includes the wildtype (WT) YU2 gp120 core, resurfaced stabilized core 3
132 (RSC3), HXB2 8b core, and their mutants containing mutations to amino acids that are known to
133 be required for binding by CD4bs or CD4i antibodies (proteins kindly provided by Dr. Mascola,
134 Vaccine Research Center). Relative levels of CD4bs and CD4i specificities were calculated as
135 the MFI of WT: MFI of mutant ratios for samples that bound to both WT and mutant with
136 MFI>100 and at least 3-fold over the MFI of matched baseline (wk0) samples.

137 **Linear epitope mapping peptide microarray.** Linear epitope mapping was performed as
138 previously described (45, 46) with modifications. Briefly, array slides were provided by JPT
139 Peptide Technologies GmbH (Berlin, Germany) by printing a peptide library designed by Dr. B.
140 Korber (Los Alamos National Laboratory) onto Epoxy glass slides (PolyAn GmbH, Germany).
141 The library contains overlapping peptides (15-mers overlapping by 12) covering 7 full-length
142 HIV-1 gp160 Env consensus sequences (Clades A, B, C, D, Group M, CRF1 and CRF2)(46).
143 Sequences of peptides contained in the peptide library have been previously published (47).
144 Three identical subarrays, each containing the full peptide library, are printed on each slide. All
145 serum samples were diluted 1:250 and hybridized to the slides using a Tecan HS4000
146 Hybridization Workstation, followed by incubation with DyLight 649-conjugated goat anti-rabbit
147 IgG (Jackson ImmunoResearch, PA). Fluorescence intensity was measured using a GenePix
148 4300 scanner (Molecular Devices) and analyzed with GenePix software. Binding intensity of the
149 post-immunization serum to each peptide was corrected with its own background value, which
150 was defined as the median signal intensity of the prebleed serum for that peptide plus 3 times
151 the standard error among the 3 subarrays on slide.

152 **Surface Plasmon Resonance (SPR) test for binding avidity.** SPR tests were performed as
153 previously described on BIAcore 4000 instruments (20, 48). Binding dissociation rate constant
154 (kd) and binding magnitude (response unit, RU) were measured for IgG purified from NHP sera,

155 at 200 µg/ml, against a panel of HIV-1 Env glycoproteins including ConS gp140, SF162ΔV2
156 gp140, MN gp120, and gp41 MN. Env proteins were immobilized as previously described, and
157 avidity score was calculated as RU/kd (20).

158 **Neutralization assays.** Virus neutralization assays were performed on TZM-bl cell line, using
159 replication competent or pseudotyped viruses grown in human peripheral blood mononuclear
160 cells (PBMC) as previously described (49). Serial dilutions of serum samples were tested for
161 neutralization of a panel of Tier 1 (SHIV-SF162P4 and SHIV-1157iEL-p, both as replication
162 competent viruses) and Tier 2 (SHIV-SF162P3.5 and SHIV-89.6P.18, as pseudotyped viruses,
163 and SHIV-89.6 and SHIV-1157ipd3N4, as replication competent viruses) SHIV viruses in TZM-
164 bl cells.

165 **ADCC assays.** ADCC assays were performed as previously described by Pollara *et al.* (50),
166 using CEM.NKR_{CCR5} cells coated with recombinant HIV-1 SF162gp120 as target cells, and
167 PBMC obtained from an HIV-seronegative donor as effector cells. The ADCC-mediating
168 antibody titer was defined as the reciprocal of the highest dilution indicating a positive GzB
169 response (>8% GzB activity) after background subtraction as previously described (50).

170
171 **Statistical analysis.** Differences in the levels of antibody responses between the 2 vaccine
172 groups or between vaccine and control groups were tested using the Wilcoxon rank sum exact
173 test with false discovery rate (FDR) controlled using the Benjamini–Hochberg method (51),
174 performed with SAS. Correlations between binding antibody responses (binding magnitude from
175 BAMA and epitope mapping assays and dissociation rate from SPR assays) and antibody
176 functions (ADCC and neutralization assay) were tested using the Spearman correlation test with
177 FDR controlled using the Benjamini-Hochberg method.

178 **RESULTS**

179 Rhesus macaques were immunized with SF162ΔV2 gp140 protein 5 times, either alone (gp140
180 group, 6 animals) or cross-linked with a CD4 mimetic miniprotein (gp140-M64U1 group, 6

181 animals) (Bogers *et al*, submitted). Env-specific antibody responses, including systemic and
182 mucosal binding specificities and antibody avidity, were evaluated with samples collected at wk
183 6 (2 weeks post 2nd immunization), wk 26 (2 weeks post 3rd immunization), wk38 (2 weeks post
184 4th immunization), and wk107 (time of 5th immunization that is 71 weeks after 4th immunization).

185 **Early Env-binding IgG response with gp140-M64U1 vaccine.**

186 To characterize the development of Env-specific binding antibody responses over time, we
187 tested longitudinal serum samples of the vaccinated animals for their binding to
188 SF162gp140ΔV2 (the immunogen), ConS gp140 (Group M consensus (52-54), MN gp120, and
189 MN gp41 proteins in binding antibody multiplex assays (BAMA). Among these 4 Env antigens
190 tested, the highest response was seen in binding to SF162gp140ΔV2 (the vaccine strain),
191 followed by ConS gp140. Similar kinetics were observed for the development of the Env-specific
192 IgG responses against the 4 Env antigens examined. Serum IgG specific for the Env proteins
193 were detectable as early as wk 6 (2 weeks after the 2nd immunization) for all 4 Env antigens
194 tested in both the gp140 and gp140-M64U1 groups (**Fig 1A-1D**). The responses generally
195 peaked at wk 26 (2 weeks after the 3rd immunization), with wk 38 (2 weeks after the 4th
196 immunization) levels comparable to that of wk 26 for both groups. The responses measured at
197 wk 107 (71 weeks after the 4th immunization) declined as expected, followed by a boost in the
198 responses measured at wk 113 (6 weeks after the 5th immunization) (**Fig 1A-1D**).

199 While the peak levels of binding antibody responses (wk 26 and wk 38) were generally
200 comparable between the two groups, the gp140-M64U1 group showed significantly higher
201 binding antibody responses at wk 6, revealing faster kinetics in the development of the anti-Env
202 responses. For all 4 Env proteins tested, binding by the wk 6 sera was much higher for the
203 gp140-M64U1 group compared to the gp140 group, with a FDR_*p* value (Wilcoxon rank sum
204 exact test *p* value controlled for false discovery rate (FDR) with the Benjamini-Hochberg
205 method) of 0.014 (**Fig. 1A-1D, Table 2**). Binding responses to all 4 Env proteins were again

206 comparable between the gp140 and the gp140-M64U1 groups after the last immunization at wk
207 113 (**Fig. 1A, Table 2**).

208 **Decreased Linear C1 Epitope IgG with gp140-M64U1 vaccine.**

209 Wk26 (2 weeks post 2nd immunization, the peak immunity time point) serum samples from all
210 immunized animals were profiled for binding antibodies against gp160 linear epitopes using
211 peptide microarray. The HIV-1 Env peptide library contains overlapping peptides covering 7 full-
212 length consensus gp160 sequences (clade A, B, C, D, group M, CRF01 and CRF02). Serum
213 IgG from both the gp140 and gp140-M64U1 groups bound epitopes in the C1, C2, V3, C4, V5
214 and C5 regions of gp120 (**Fig. 2A, 2B, and 2C**) and the gp41 immunodominant (ID) region of
215 gp41 (**Fig. 2A, 2D and 2E**). The magnitude of binding to these epitopes was generally
216 comparable between the 2 immunized groups at wk 26 (**Fig. 2A**), with the exception of epitope
217 C1.2-binding, which was significantly higher for the gp140 group compared to the gp140-M64U1
218 group (FDR_p = 0.038; **Fig. 2B and 2C, Table 2**). Interestingly, this C1.2 linear epitope was
219 identified in epitope mapping studies of the RV144 Thai trial, and plasma IgA binding to the
220 corresponding C1 peptide covering the entire epitope region (C1_104. AE:
221 MQEDVISLWDQSLKPCVKLTPLCV) correlated with increased risk of HIV-1 infection (*i.e.*
222 decreased vaccine efficacy) in the secondary/exploratory immune correlate analysis of the trial
223 (20). To further evaluate the kinetics and magnitude of this response, we measured the level of
224 serum IgG response to linear C1_104.AE peptide over time by BAMA. Binding response against
225 C1_104.AE was significantly higher for the gp140 group than the gp140-M64U1 group at wk26
226 (FDR_p=0.014; **Fig. 2F, Table 2**), which is consistent with the trend observed in wk26 linear
227 epitope mapping data (**Fig. 2 A, B, and C**). Similar to binding responses against Env proteins,
228 binding responses to C1_104.AE peaked at wk 26 and wk 38, declined at wk107, and then
229 increased again at wk113, after the fifth immunization.

230 We modeled this C1_104 epitope in the monomeric subunit of gp120 from the SOSIP Env trimer
231 structure(55), which is representative of the pre-fusion conformation, and found that it is

232 exposed on the monomeric gp120 surface (**Fig. 2G**, red ribbon). In the CD4-bound state, the
233 formation of the bridging sheet results in the C-terminal half of the C1_104 epitope bending ~90
234 degrees relative to the epitope in the SOSIP structure (**Fig. 2G**, pink ribbon). This bending
235 results in a >30Å displacement in the position of the C-terminal residue of the C1_104 epitope,
236 which in turn contacts CD4(56). Given the large conformational change and associated burial of
237 C-terminal residues upon contacting CD4, antibodies that recognize C1_104 in the unbound
238 conformation therefore may not be able to recognize the epitope in the CD4 bound state. While
239 the effect of CD4 binding on the conformation of the C1_104 epitope in a V2 deleted gp140 may
240 be different, these structural data do suggest that the CD4bs-cross-linked antigen may
241 substantially impact exposure of the C1 epitope on the Env immunogen.

242 **Induction of CD4 binding site (CD4bs) antibodies by vaccination.**

243 Since the design of the gp140-M64U1 crosslinked immunogen involved potential modifications
244 of gp120-CD4 interactions, we evaluated the level of CD4 binding site (CD4bs) and CD4-
245 inducible (CD4i) antibodies by measuring binding of the antibodies to gp120 structures with and
246 without mutations that are known to interfere with recognition of CD4bs and CD4i epitopes (57).
247 In particular, the D368R mutation abrogates binding of most CD4bs antibodies to gp120 core or
248 gp120 (28, 57-60), Δ371 abrogates binding of VRC01-like antibodies to gp120 resurfaced
249 stabilized core (RSC3) (57, 59), and the I420R mutation abrogates binding of gp120 core to
250 17b-like CD4i antibodies (28, 59). With these reagents, we detected CD4bs binding antibodies
251 (indicated by YU gp120 core WT:D368R ratios ≥ 2.5) in both vaccination groups (**Fig. 3A**) with
252 comparable levels between the 2 groups (**Table 2**). Furthermore, VRC01-like binding antibodies
253 (indicated by RSC3 WT:Δ371 ≥ 2.5) developed in both vaccination groups at generally
254 comparable levels (**Fig. 3A, Table 2**). 17b-like CD4i antibodies, defined as HXB2 8b core
255 WT:I420R ≥ 2.5 , were not induced (**Fig. 3A**).

256 **Early increase in antibody avidity with gp140-M64U1 vaccine.**

257 Maturation of the vaccine-elicited antibody response through determination of HIV-1 Env
258 antibody avidity is an indicator of the quality of the vaccine-induced antibody responses. We
259 measured the avidity (as dissociation rate constant (off-rate), k_d , and avidity score, RU/ k_d) of
260 purified serum IgG (from wk 6, wk 26, wk 38, wk 107, and wk 113) for binding to SF162
261 gp140 Δ V2 (**Fig. 3B**), MN gp120 (**Fig. 3C**), MN gp41 (**Fig. 3D**), and ConS gp140 (**Fig. 3E**). The
262 avidity scores of serum IgG to these antigens peaked at wk26 and wk38 (**Fig. 3F**), and off-rates
263 dropped to lowest levels (slowest off-rates) at the same time-points (**Fig. 3B-3F**). At wk 6, off-
264 rate for SF162 gp140 Δ V2 was significantly slower in the gp140-M64U1 group compared to the
265 gp140 group (median 1.7×10^{-4} versus $1.0 \times 10^{-3} \text{ S}^{-1}$ for gp140-M64U1 and gp140 groups
266 respectively, $\text{FDR}_p=0.022$, **Fig. 3B, Table 2**). Off-rates were not statistically different, after
267 FDR correction, for the two vaccine groups at wk 26, wk 38, and wk 113 (**Fig. 3B-3F, Table 2**).
268 The longitudinal patterns of antibody off-rates and avidity score for gp41, gp120, and ConS
269 gp140 were similar to that for SF162 gp140 Δ V2, with the gp140-M64U1 group trending toward
270 having a slower off-rate (**Fig. 3C,3D, and 3E**) and higher avidity score (**Fig 3F**) than the gp140
271 group.

272 **Serum IgG Env binding avidity and magnitude correlate with ADCC and neutralization.**

273 We further explored correlations between binding antibody properties (binding MFI and off-
274 rates) and antiviral functions (neutralization and ADCC) of antibodies elicited in the study.
275 Vaccinations elicited low to moderate levels of neutralizing antibodies against SF162P4, with
276 titers ranging from <10 to 4403 at the peak neutralizing activity time point of wk 38 (post 3rd
277 immunization) in most animals (Bogers *et al*, submitted). Neutralization of SHIV SF162P4 at wk
278 38 was found to correlate significantly with wk 38 serum IgG binding to SF162 gp140 Δ V2
279 ($\text{FDR}_p=0.003$, Spearman $r=0.97$; **Fig. 4A and Table 3**). Wk 38 neutralization of SHIV
280 SF162P4 was also found to correlate with a faster off-rate for SF162 gp140 Δ V2 at wk 6
281 ($\text{FDR}_p=0.006$, Spearman $r=0.87$; **Fig. 4B**) which indicated an inverse correlation with avidity;

282 however wk 38 neutralization was not significantly correlated with contemporaneous (wk 38) off-
283 rate for SF162 gp140 Δ V2 (**Table 3**).

284 Both vaccine groups developed strong ADCC activity measured with SF162 gp120-coated cells,
285 which peaked at wk26 after the 2nd immunization with titers up to 19,024 (Bogers *et al*,
286 submitted). ADCC titers were significantly higher for the gp140-M64U1 group compared to the
287 gp140 group (FDR_ p = 0.014) at wk 26, and trended higher at wk 113 (**Table 2**). Correlation
288 analysis revealed that ADCC activity at wk 26 (post 3rd immunization) was not correlated with
289 either contemporary (wk26) binding magnitude or avidity for SF162 gp140 Δ V2, but rather
290 correlated with wk6 (post 2nd immunization) serum IgG binding (FDR_ p =0.003, Spearman
291 r =0.90; **Fig. 4C**) and avidity (FDR_ p =0.035, Spearman r =-0.73 for off-rate; **Fig. 4D** and **Table 3**)
292 for SF162 gp140 Δ V2, indicating that binding antibody responses early on may predict later
293 antibody functions following further immunizations.

294 **Low level of serum IgA elicited.**

295 Env-specific IgA responses were evaluated in longitudinal serum samples. The overall
296 magnitudes of HIV-1 Env serum IgA responses were much lower than serum IgG responses
297 (**Fig. 5A vs. Fig. 1A**), with IgA binding positivity rates of 66.7% and 66.7% at wk 26 for SF162
298 gp140 Δ V2 for gp140 and gp140-M64U1 groups, respectively, compared to 100% and 100% for
299 IgG binding to SF162 gp140 Δ V2 at wk 26. Similar to serum IgG responses, serum IgA binding
300 to SF162 gp140 Δ V2 peaked earlier for the gp140-M64U1 group, at wk 6, compared to wk 26 for
301 the gp140 group (**Fig. 5A**). However, no significant difference between the two groups in the
302 magnitude of responses was detected for wk6 or for any time point (**Fig. 5A, Table 2**).

303 **Vaccine-elicited mucosal antibody responses.**

304 Nasal and rectal samples were collected from vaccinated animals at wk 38. Env-specific IgG
305 responses were evaluated in these mucosal samples using BAMA (29, 43). Binding magnitude
306 (MFI) was normalized to total recovered rhesus IgG concentration (μ g/ml) in each mucosal
307 sample to account for sampling variations. Total rhesus IgG ranged from <0.5-109 μ g/ml

308 (median 9.1 µg/ml) and <0.5-165 µg/ml (median 9.9 µg/ml) for nasal and rectal samples,
309 respectively. We detected Env-specific IgG against SF162 gp140ΔV2, MN gp120, and MN gp41
310 in nasal washes from both the gp140 and gp140-M64U1 groups with comparable magnitudes
311 (**Fig. 5B**, and data not shown). When compared to the mock immunized control animals, nasal
312 samples from the gp140 group showed significantly higher levels of SF162 gp140ΔV2 specific
313 antibodies (FDR_ $p=0.022$, **Table 2**). The specific IgG binding of the rectal washes from the
314 vaccinated animals to these Env proteins was not statistically different from that of control
315 animals (data not shown). We further examined the correlation between IgG responses in the
316 serum and the mucosal compartments and found a lack of significant correlation between serum
317 and nasal IgG responses for binding to SF162 gp140ΔV2 (**Fig. 5C**), indicating that these are
318 distinct immune measurements.

319

320

321 **DISCUSSION**

322 Here we report on the detailed binding specificities, avidity, kinetics and functional correlations
323 of antibodies generated by immunization of rhesus macaques with an HIV-1 envelope protein
324 (SF162ΔV2 gp140) cross-linked with a CD4 mimetic miniprotein, M64U1 (Bogers *et al*,
325 submitted). Our findings demonstrate that cross-linking of the CD4 mimetic M64U1 with gp140
326 significantly impacts the kinetics, binding specificity, avidity and ADCC activity of the vaccine-
327 elicited antibodies compared to that of gp140 protein alone. Comparison of the binding antibody
328 responses between the gp140 and the gp140-M64U1 groups revealed an accelerated
329 development of anti-Env binding responses in the gp140-M64U1 group, as indicated by higher
330 binding to gp120 and gp140 Env proteins compared to the gp140 alone group at wk 6 (post 2nd
331 immunization) (**Fig.1, Table 2**). However, Env binding responses became comparable by the
332 time antibody responses peaked (at wk 26 and wk 38, post 3rd and 4th immunization,
333 respectively), whereas binding to a linear C1 epitope was higher for the gp140 group compared

334 to the gp140-M64U1 group at wk 26. Antibody responses against M64U1 or CD4 were not
335 measured in this current study. Follow-up studies could examine whether anti-immunogen
336 responses were elicited and could have impacted gp140 antibody responses in the gp140-
337 M64U1 group following later boosts.

338

339 In previous study in rabbits (42), the gp140-M64U1 complex elicited significant levels of CD4i
340 antibodies as measured by absorption/depletion with gp120 proteins carrying the I420R
341 mutation, which is critical for binding by 17b-like CD4i antibodies, and by neutralization of a HIV-
342 1 virus with and without the presence of soluble CD4. In the current NHP study, no significant
343 17b-like CD4i antibody responses were detected in either the gp140 or the gp140-M64U1 group
344 when examining the differential binding of serum to gp120 core protein with and without the
345 I420R mutation (**Fig. 3A**). Another difference between the previous rabbit study and the current
346 macaque study is the higher levels of neutralizing antibodies directed to the CD4i epitopes
347 observed in the rabbit study following gp140-M64U1 immunization but not the current macaque
348 study (Bogers *et al.*, submitted). Apart from differences in study methods, species differences
349 may play a role in the difference observed. Macaques have intrinsic expression of CD4
350 molecules along with other surface molecules including co-receptor and DC-SIGNs (61-63) that
351 could interact with and SIV and HIV Env, which likely affects the responses of macaques to a
352 miniCD4-crosslinked Env. One concern for the use of CD4 mimetic proteins in vaccine
353 regimens is the potential effect on the development of CD4bs antibodies. Broadly neutralizing
354 CD4bs antibodies have been shown to recognize a site of “vulnerability” on the HIV-1 Env (64).
355 Binding antibodies directed to CD4bs are commonly induced in HIV infection (57), but
356 unfortunately those with broadly neutralizing activity seem to develop in a smaller subset of
357 individuals (57, 65). CD4bs antibodies were detected in the gp140 group in the rabbit study (42).
358 In the current study, we also found comparable levels of CD4bs antibodies in both the gp140
359 and the gp140-M64U1 groups (**Fig. 3A**).

360 One surprising finding in this study is the impact of M64U1-Env crosslinking on the
361 kinetics, specificity, and avidity of antibody responses. Both the binding magnitude and avidity of
362 the Env-specific antibodies were significantly higher (FDR_ $p=0.014$) for the gp140-M64U1
363 group at wk 6 (post 2nd immunization), although the two groups either were comparable or the
364 gp140 group trended higher than the gp140-M64U1 group at later time points (**Fig. 1A-1D, and**
365 **Fig. 3C, Table 2**). The mechanisms for the faster development of antibody responses in the
366 gp140-M64U1 group are not clear and warrant further investigation, including whether
367 crosslinking of M64U1 and gp140 can affect the stability and *in vivo* trafficking of the Env
368 protein, and how the crosslinking with M64U1 affects the interaction of Env with cells of both the
369 adaptive and innate immune systems. In particular, exploring of the B cell responses in this
370 macaque study revealed higher proportions of Env-specific B cells in peripheral blood
371 mononuclear cells (PBMC) (Bogers *et al.*, submitted). Bogers *et al.* hypothesized that
372 crosslinking with M64U1 interferes with CD4 receptor engagement, thus improving CD4 T cell-
373 dependent immune responses.

374 In contrast to the binding results with the Env proteins, binding to a C1 epitope, C1_104:
375 MQEDVISLWDQSLKPCVKLTPLCV (sequence matches that of AE clade consensus), was
376 significantly higher for the gp140 group compared to the gp140-M64U1 group at the peak
377 immunity time point of wk 26, as shown by both linear epitope mapping microarray and by
378 BAMA (**Fig. 2A, 2B, and 2F, Table 2**). Plasma IgA responses to this same epitope were
379 positively correlated with HIV-1 risk in the human RV144 vaccine clinical trial (20). Quantification
380 of the anti-C1.2 IgA response was not possible in this study due to the low levels of overall IgA
381 responses. Characterization of IgA responses against this C1 epitope and its correlation with
382 ADCC response warrant further investigation. In addition, even though conformational C1-
383 binding IgA has been indicated as potentially blocking IgG-mediated ADCC activity (66) and
384 monoclonal IgG antibodies targeting conformational C1 epitopes can synergize with V2

385 antibodies for increased ADCC and neutralizing activities (50), the role of C1-linear binding IgG
386 in vaccine protection is not yet understood.

387 Another interesting finding in the study was the significantly higher ADCC activity in the
388 sera of animals in the gp140-M64U1 group at wk26 (Bogers *et al.*, submitted, and **Table 2**).
389 ADCC activity was not measured for wk 6 serum, the only time point where Env-binding
390 magnitude was higher in the gp140-M64U1 group compared to the gp140 group. ADCC activity
391 at wk 26 significantly correlated with wk6 Env binding magnitude and off-rate (**Fig. 4C and D**),
392 but not with wk26 (contemporary) binding magnitude or off-rate (**Table 3**). The brisk and avid
393 antibody response may be a biomarker for another underlying (and unmeasured) mechanism
394 that led to enhanced ADCC function or alternatively, the early antibody response directly
395 impacted the immune mechanisms resulting in higher ADCC function. Interestingly, ADCC
396 activity was also found to correlate with proportions of Env-specific B cells in peripheral blood in
397 the same study (Bogers *et al.*, submitted). Wk38 serum neutralizing activity, on the other hand,
398 correlated with contemporary IgG binding magnitude (**Fig. 4A**) but not the contemporary IgG
399 Env avidity; it also correlated with a faster off-rate (indicating lower avidity) at the earlier time
400 point of wk6 (**Fig. 4B**) The discordant correlations of ADCC and neutralizing activities with
401 binding and avidity are in agreement with the observations from Guan *et al.* (67), suggesting
402 that different Env specificities are involved in ADCC and neutralizing anti-viral functions.

403
404 Env-specific antibodies were detected in nasal samples in both the gp140 and gp140-
405 M64U1 groups, with no difference in IgG levels between groups. The level of Env-specific IgG in
406 the nasal compartment did not correlate with serum IgG. This could be explained by selective
407 transportation of serum IgG into mucosal compartments, variation in transportation efficiency
408 among animals, or local production of IgG at the mucosal compartments. The Env gp140 used
409 in this vaccine study does not contain V2. This was based on an earlier finding of higher titers of
410 cross-reactive neutralizing antibodies in rhesus macaques immunized with SF162 V2-loop

411 deleted gp140 compared to those immunized with SF162 gp140 (33, 68). In light of the RV144
412 immune correlation found between plasma anti-V2 IgG and decreased risk of infection (20),
413 further studies to improve upon this vaccine platform could include the addition of the V2 region
414 in the vaccine immunogen to enable induction of V2-specific responses.

415

416 In summary, data from this study indicate that immunizing with an Env protein cross-
417 linked to the CD4 mimetic miniprotein (M64U1) induced accelerated Env binding magnitude and
418 avidity (as early as 2 weeks post 2nd immunization). In addition, crosslinking of gp140 with
419 M64U1 modulated particular epitope specificities of antibody responses, such as inducing
420 higher C1_104.AE responses in the gp140 group, likely due to alterations in the envelope
421 structure that modulate exposure of this region upon CD4 binding. Lastly, ADCC activity at peak
422 immunity time points (which were higher for the gp140-M64U1 group compared to the gp140
423 group) correlated with the magnitude and avidity of Env binding responses at an earlier time
424 point before the ADCC and binding antibody responses reached peak levels. Taken together,
425 these data indicate that structural modification of HIV-1 Envelope immunogens by mimicking the
426 CD4 bound state can modulate epitope exposure in a way that substantially impacts the
427 specificity and function of the elicited antibody responses.

444 **Figure Legends**

445 **Figure 1.** Longitudinal binding antibody responses for SF162 gp140 Δ V2 (vaccine strain) (**A**),
446 ConS gp140 (**B**), MN gp120 (**C**), and MN gp41 (**D**). Shown are MFI binding values within the
447 linear range of the assay for each antigen (1:400 for SF162 gp140 Δ V2 and MN gp41; 1:80 for
448 ConS gp140 and MN gp120). The gp140 group is shown in blue, and the gp140-M64U1 group
449 in red. For improved data visualization of data points with similar magnitude, the x-axis is plotted
450 categorically with staggered symbols so each data point is visible. One animal in the gp140-
451 M64U1 died before wk107, and serum samples were not available for another 3 animals in the
452 gp140-M64U1 group at wk107, therefore leaving 2 data points for wk107 and 5 data points for
453 the gp140-M64U1 group. Green arrows below x-axis indicate time of vaccinations. FDR_ p :
454 Wilcoxon rank sum exact test p value controlled for false discovery rate (FDR) with the
455 Benjamini-Hochberg method. * indicate FDR_ p <0.05.

456

457 **Figure 2.** Linear epitope specificity of serum IgG by epitope mapping (**A-E**) and BAMA (**F**). Wk
458 26 mean binding intensity values of serum IgG for the gp140 only (B, D) and gp140-M64U1
459 (C,E) groups are shown for overlapping peptides of 7 consensus gp120 (B,C) and gp41 (D, E)
460 sequences, respectively. Different colors represent different clade/circular recombinant forms
461 (CRFs). Epitope regions identified in the study are indicated with text over horizontal bars in

462 plots. **(A.)** Magnitude of binding to each epitope, calculated as the highest binding to a single
463 peptide within each epitope region, wherein percentage numbers listed under each epitope are
464 the response rates to the epitope by the 2 groups (gp140 vs. gp140-M64U1). The peptide
465 ranges for the epitopes are: C1.1: #16-21; C1.2: #32-39; C2: #65-68; V3: #97-104; C4: #133-
466 139; V5-C5: #147-151; C5.1: #152-159; C5.2: #161-163; gp41-ID: #187-194. Sequences for all
467 peptides have been previously published (47). Longitudinal binding to C1_104.AE peptide
468 (corresponds to C1.2 epitope in epitope mapping) was measured by BAMA and is shown in
469 panel F. Green arrows indicate time of immunizations. **(G.)** Structural modeling of the
470 conformational change of the C1 epitope upon CD4 binding. The C1_104 epitope bends ~90
471 degrees from the unliganded gp120 conformation (gp120 monomer from SOSIP Env trimer;
472 PDB 4TVP; beige) to the CD4 liganded gp120 conformation (PDB 4RQS; light blue). Binding of
473 CD4 (PDB 4QRS; green) results in a >30Å displacement of the C-terminal residue (stick
474 representation) between the C1_104 epitope in the unliganded gp120 (red) versus the CD4
475 bound C1_104 epitope (magenta).

476

477

478 **Figure 3.** CD4bs and CD4i specificity **(A)** and off-rate measurements for SF162 gp140ΔV2 **(B)**,
479 MN gp120, **(C)**, MN gp41 **(D)**, and ConS gp140 **(E)** in the 2 vaccine groups, and the group
480 mean off-rates and avidity score values measured by SPR are shown **(F)**. The cutoff for the
481 CD4bs and CD4i differential binding assay (A) is 2.5-fold. For the CD4bs/CD4i differential
482 binding assay, b12 (CD4bs mAb) was used as positive control for YU gp120 Core WT:D368R
483 differential binding and RSC3 WT:Δ371 differential binding (57), and 17b (CD4i mAb) was used
484 as positive control for HXB2 8b core WT:I420R differential binding (28, 57). Serum samples
485 were tested at 1:400. Control mAbs b12 and 17b were tested as 25 and 50 µg/ml, respectively.
486 All baseline serum samples were negative for binding to both the WTs and mutants in this test

487 panel. Green arrows indicate times of immunizations. FDR_p: Wilcoxon rank sum exact test *p*
 488 value controlled for false discovery rate (FDR) with the Benjamini-Hochberg method. * indicate
 489 FDR_p<0.05. Between-group comparison test results are shown in Table 2.

490
 491 **Figure 4.** Correlation of neutralization (**A,B**) and ADCC (**C,D**) activities with serum IgG binding
 492 magnitudes (A&C) and serum IgG avidity (B&D). Spearman correlation analysis was performed
 493 using SAS, and *p* values are FDR corrected across all between-group comparison tests (Table
 494 2) and this correlation test (Table 3). ** FDR_p<0.01; * FDR_p<0.05.

495
 496 **Figure 5.** Longitudinal binding of serum IgA to SF162 gp140ΔV2 (**A**), wk 38 nasal IgG binding to
 497 SF162 gp140ΔV2 (**B**), and correlation between serum and nasal IgG binding to SF162
 498 gp140ΔV2 at wk 38 (**C**). MFI binding values shown for IgA binding are from 1:80 serum dilution.
 499 Binding specificities for nasal samples were normalized by total IgG concentration in each
 500 sample. Green arrows indicate time of immunizations *FDR_p<0.05 (Wilcoxon Rank Sum Exact
 501 Test, FDR correction with Benjamini & Hochberg method).
