Running title: Trusting forecasts

# TRUSTING FORECASTS

## Abstract

Accurate forecasting is necessary to remain competitive in today's business environment. Forecast support systems are designed to aid forecasters in achieving high accuracy. However, studies have shown that people are distrustful of automated forecasters. This has recently been dubbed 'algorithm aversion'. In this study, we explore the relationship between trust and forecasts, and if trust can be boosted in order to achieve a higher acceptance rate of system forecasts and lessen the occurrence of damaging adjustments. In a survey with 134 executives, we ask them to rate the determinants of trust in forecasts, what trust in forecasting means to them and how trust in forecasts can be increased. The findings point to four main factors that play a role in trusting forecasts: (1) the forecast bundle, (2) forecaster competence, (3) combination of forecasts, and (4) knowledge. Implications of these factors for designing effective forecast support and future-focused management processes are discussed.

Keywords: trust, forecast, judgment, algorithm aversion

Word Count: 7592

## Introduction

Accurate forecasting is indispensable for organisations to remain competitive. Forecast support systems are designed to aid decision makers in attaining acceptable forecasts. However, a plethora of studies have shown that people are sceptical of predictions handed to them by forecast support systems or by other forecasters (e.g., Dietvorst, Simmons, & Massey, 2015; Fildes, Goodwin, Lawrence, & Nikolopoulos, 2009; Önkal, Gönül, Goodwin, Thomson, & Öz, 2017; W. Wang & Benbasat, 2005). The literature on advice taking argues that such distrust may be viewed as a form of advice discounting. Forecasters overweigh their own judgment and continuously adjust forecasts provided to them. This judgmental adjustment of statistical forecasts is the prevalent practice in business forecasting (Fildes & Petropoulos, 2015). However, field studies have found that such adjustment is not always warranted: forecasters adjust the output they receive from statistical forecasting models ('model advice'), often when there is no reason for such adjustment and it in fact damages forecast accuracy (e.g. Baecke, De Baets, & Vanderheyden, 2017; Fildes et al., 2009; Van den Broeke, De Baets, Vereecke, Baecke, & Vanderheyden, 2018). One reason that has been put forward recently is referred to as 'algorithm aversion': people are averse to using advice from algorithms and are unforgiving towards any errors made by the algorithm (Dietvorst et al., 2015; Prah & Van Swol, 2017). While the combination of algorithms and human decision makers has the potential to lead to improved accuracy, in practice, the advice of the algorithm is often discounted by the human member of the human-algorithm dyad. One way to alleviate this so-called advice discounting, is to boost trust in the source of advice. Trust is a vital moderator in the relationship between the reliance on computer-assisted forecasts (Dzindolet, Pierce, Beck, & Dawe, 2002; Madhavan & Wiegmann, 2007) and the heuristics a forecaster uses in producing the final predictions (Alvarado-Valencia & Barrero, 2014). Increasing trust may therefore lead to more acceptance and to less damaging adjustments. However, how this enhancement should be achieved is not yet clear. Goodwin, Gönül, and Önkal (2013) lay the groundwork for this workstream and find that trust is influenced by the complexity of the time series

1  
2  
3 that are being forecast. We build further on their work and employ a survey to investigate explicitly  
4 what forecasters deem important for trusting forecasts. In doing so, this paper presents the findings  
5 from a trust survey and reveals four main clusters affecting trust: (1) the forecast bundle, (2) forecaster  
6 competence, (3) combination, and (4) knowledge. This is supplemented by analysing the responses to  
7 two qualitative questions focusing on (i) what trusting forecasts means to decision-makers, and (ii)  
8 how it can be improved.  
9

10  
11  
12  
13  
14  
15  
16 Importantly, literature has been looking for a way to stop forecasters from making harmful  
17 adjustments to forecasts provided to them. However, directly intervening in the forecast support  
18 systems has thus far been unsuccessful (e.g., Goodwin, Fildes, Lawrence, & Stephens, 2011). Indirectly,  
19 enhancing trust may lead to a decline in the detrimental adjustments made by forecasters. The 'trust  
20 in forecasting' survey used in this study can serve as a diagnostic tool for further research in this field.

### 30 **Literature**

31  
32 Judgmental adjustments to model forecasts are the most common way of forecasting in  
33 business practice (Fildes & Petropoulos, 2015). These adjustments are often unnecessary and  
34 damaging to forecasting quality (e.g., Fildes et al., 2009). So why do forecasters adjust so often? A  
35 number of explanations are possible. First, it has been suggested that people adjust because of a need  
36 of a sense of ownership and/or a sense of control over the forecasting process (Önkal & Gönül, 2005).  
37 Second, people may discern patterns in noise where there is none (Fildes et al., 2009). Third,  
38 forecasters may alter the outcomes in order to continue receiving feedback. When tasks become  
39 automated, people may feel like they are at risk of becoming de-skilled by not participating in the task  
40 (Bainbridge, 1983). Fourth, changes are sometimes made because of political reasons or confusion  
41 with target setting (Fildes & Hastings, 1994; Goodwin, 1996). Fifth, people suffer from algorithm  
42 aversion: they are distrustful of algorithms and punish them severely for any error that is detected  
43 (Dietvorst et al., 2015; Prahla & Van Swol, 2017). Yet, models can generate predictions based on the  
44 logical and systematic processing of information and can handle large amounts of data (Goodwin &  
45  
46  
47  
48  
49  
50  
51  
52

55  
56  
57  
58  
59  
60

1  
2  
3 Wright, 2010). The advantage of models is that their predictions have a high degree of consistency and  
4 generate fewer errors than human judgment (Blattberg & Hoch, 1990). Models can thus improve  
5 forecasting performance by increasing the consistency of predictions (Hoch & Schkade, 1996).  
6  
7 Interestingly, in an experimental study concerning the use of decision support systems, Goodwin,  
8 Fildes, Lawrence, and Nikolopoulos (2007) found that participants ignored the “advice” of the system  
9 on which model to use (in the form of an “optimize” button). Only in 14.1% of the forecasts examined  
10 was the optimize button used, and only in 9.2% of the total examined forecasts was the advised  
11 method eventually chosen. Similarly, Lim and O’Connor (1995) found a tendency among forecasters to  
12 persist with damaging adjustments in subsequent forecasts, despite the feedback that they were  
13 reducing accuracy. People making forecasts are in general overconfident as well in the performance of  
14 their forecasts (Arkes, 2001; Bovi, 2009; Lawrence, Goodwin, O’Connor, & Önkal, 2006) and suffer from  
15 self-serving attribution bias, whereby they overestimate the importance of their own judgment when  
16 making adjustments to statistical forecasts (Hilary & Hsu, 2011; Libby & Rennekamp, 2012). Decision  
17 makers seem to discount advice from statistical forecasts (Önkal, Goodwin, Thomson, Gönul, &  
18 Pollock, 2009). The advice literature shows us that they tend to discount advice relative to their own  
19 judgment (Harvey & Fischer, 1997; Lim & O’Connor, 1995), even when it has the potential to improve  
20 their accuracy (Yaniv, 2004a). Judges weight their own judgment more heavily, and incorporate advice  
21 only to a limited degree: only 20-30% on average of the advice is taken into account (Harvey & Fischer,  
22 1997).

23  
24  
25 Trust can play an important role in whether advice is fully accepted or discounted (Sniezek &  
26 Van Swol, 2001; Wang & Du, 2018) and may thus have an effect on the acceptance of forecasting  
27 algorithms in everyday business practice. Many definitions of trust exist, but in accordance with  
28 previous studies on trust in forecasting (Goodwin et al., 2013), we focus on the definition of Johnson-  
29 George and Swap (1982): “a psychological state comprising the intention to accept vulnerability based  
30 on positive expectations of the intentions or behaviour of another” (p.395). Importantly, the definition  
31 points towards vulnerability of the advice taker: taking advice has an inherent risk to it, as one needs

1  
2  
3 to rely on the benevolence, integrity and ability of the advice giver (Mayer, Davis, & Schoorman, 1995).  
4  
5 One could therefore state that trust is relevant in situations which have an inherent uncertainty to  
6  
7 them (Mayer et al., 1995; Snizek & Van Swol, 2001). Such is the case with forecasts: when predicting  
8  
9 the future, uncertainty is generally high. Accepting forecasts from another, be it another person or an  
10  
11 algorithm, requires the acceptance of this uncertainty and the trust that the other has a certain degree  
12  
13 of relevant expertise. Such trust seems to be especially difficult when receiving advice from an  
14  
15 algorithm (Dietvorst et al., 2015; Kleinmuntz, 1990; Lim & O'Connor, 1995; Önkal et al., 2009).  
16  
17 According to Alvarado-Valencia and Barrero (2014), trust is a moderator in the relationship between  
18  
19 heuristics and reliance, and affects the final forecast behaviour. Heuristics are the strategies used to  
20  
21 simplify the forecasting task into something more manageable, and reliance implies the degree of  
22  
23 acceptance of a computer-assisted forecast (i.e., will the forecaster adjust or not). Trust then affects  
24  
25 heuristics and reliance in such a way that it can lead to different adjustment behaviour of forecasts or  
26  
27 assignment of different weights to forecasting cues (Alvarado-Valencia & Barrero, 2014; Lee & See,  
28  
29 2004). Trust can be a personal trait, an appraisal of the credibility of the source or a consequence of  
30  
31 the context (Alvarado-Valencia & Barrero, 2014). While trust as a personality trait cannot be  
32  
33 influenced, the other two perspectives can. Source credibility for instance, can be influenced by  
34  
35 highlighting previous successes of the forecaster/computer in question, via visibility of the system or  
36  
37 comprehensible measures of accuracy (Dou, Walden, Lee, & Lee, 2012; Edwards, Spence, Gentile,  
38  
39 Edwards, & Edwards, 2013). These findings stem from human-automation interaction literature. More  
40  
41 specific to forecasting, this credibility has been deemed as one of the most important factors to  
42  
43 evaluate forecasts in a sales context by Mentzer and Kahn (1995). Additionally, forecasting literature  
44  
45 has shown that the provision of explanations may also increase trust in system forecasts (Gönül, Önkal,  
46  
47 & Lawrence, 2006; Önkal, Gönül, & Lawrence, 2008).

54 But what are the determinants of trust exactly? Human-automation literature suggests that  
55  
56 trusting a decision support system can be a complicated function of multiple variables, including  
57  
58 perception of the source, actual credibility, and perceived source credibility. Given a fundamental  
59  
60

1  
2  
3 understanding of decision support systems, decision makers filter their observations through their  
4 perceptions and biases to arrive at a specific level of trust (Madhavan & Wiegmann, 2007). In the  
5 forecasting field, a study by Goodwin et al. (2013) has shown that the complexity of the series that is  
6 forecasted is an antecedent to trust. More specifically the level of noise is found to have an inverse  
7 relationship with trust, and that the presence of trends decreased the level of trust. Equally important  
8 was the formulation of the boundaries of the interval forecasts: an interval formulated as best-  
9 case/worst-case led to higher trust than 'upper bound and lower bound' formulations. Thus, trust can  
10 have an effect on the level acceptance of forecast advice in a number of ways. Given the continued  
11 struggle of businesses to have their forecasters accept the advice of the forecasting software without  
12 damaging adjustments, working on the level of trust may prove to be an important factor in  
13 heightening this acceptance.

25  
26  
27  
28 The current study can be seen as a further attempt to explore the determinants of trust in  
29 forecasting via a survey employed on forecasting practitioners. The details of the sample and the  
30 procedure follows next:  
31  
32  
33

### 34 35 36 37 **Method**

#### 38 39 *Sample*

40  
41 A survey was sent out to 138 people from the professional networks of the researchers. They  
42 were all practicing forecasters with experience in making their professional forecasts as well as using  
43 forecasts made by others. Participants worked in different companies across various sectors in Turkey  
44 and there were no academics. One hundred and thirty-four complete surveys were returned, resulting  
45 in a response rate of 97.10%.

#### 46 47 48 49 50 51 52 *Design*

53  
54 The survey questionnaire items were based on extensive discussions with executives and  
55 managers participating in the Executive MBA programme at Bilkent University. These executives held  
56 a minimum of five years of forecasting experience in order to be accepted to the programme.  
57  
58  
59  
60

### Procedure

After their consent, participants were first asked to indicate the sector they worked in, their job experience (in years), how long they have been using other people's forecasts in their job (in years), how long they have been making their own forecasts (in years), how they would rate their own knowledge of forecasting techniques – a self-assessed rating of expertise (5-point scale from 1: None at all to 5: Very high/extensive), how much trust they put in statistical forecasts (5-point scale from 1: None at all to 5: Very high) and how much trust they put in expert's forecasts (5-point scale from 1: None at all to 5: Very high). The survey furthermore requested the participants to complete the following open-ended statements (1) trust in forecasts means the following to me and (2) the following is required to increase/boost/enhance my trust in forecasts. Next, participants were asked to rate the factors that affect their trust in a given forecast on a Likert scale ranging from 1 to 5, with 1 indicating "Not important at all" and 5 indicating "Extremely important". They were given the opportunity to add a factor themselves if they felt the list was incomplete. Participants were subsequently thanked for their participation.

### Results

Survey respondents had an average job experience of about 11 years ( $Mean = 11.19$ ;  $SD = 6.53$ ). The most often cited sectors include the defence industry (26.5% of respondents) and the public sector (14.7%). They have been using others' forecasts for about 8 years ( $Mean = 8.22$ ;  $SD = 5.81$ ) and have been making their own forecasts for over 6 years ( $Mean = 6.63$ ;  $SD = 5.41$ ). Surprisingly, participants rated their own knowledge of forecasting techniques ( $Mean = 2.78$ ;  $SD = 1.22$ ) to be slightly below 3 (the midpoint between 1: no knowledge at all and 5: very high/extensive knowledge). A closer inspection reveals that 38.1% of the executives rated themselves as below the scale midpoint on this question, 33.6% provided a rating of exactly 3 (midpoint) and only 28.3% rated themselves to

1  
2  
3 be above the scale midpoint. The trust they place on statistical forecasts ( $Mean = 3.51$ ;  $SD = 0.89$ ) was  
4  
5 similar to the trust placed on other people's forecasts ( $Mean = 3.54$ ;  $SD = 0.79$ ) and in both cases  
6  
7 slightly above the neutral midpoint of the scale (i.e., 3).  
8  
9

10 Table 1 exhibits the scores and standard deviations of each factor, including a two tailed one-  
11  
12 sample t-test that compares the score with the neutral midpoint (a score of 3). With the exception of  
13  
14 'Forecasts are prepared by consulting with me', all items are significantly different from the neutral  
15  
16 middle point. Only 'Forecasts are prepared by consulting with me' scores below the middle point. A  
17  
18 one-tailed t-test shows this difference is significant at  $p < .05$ . Thus, consultation is the only factor that  
19  
20 is, on average, seen as less important in determining trust in forecasts. All other factors are seen as  
21  
22 important in determining trust in forecasts.  
23  
24  
25  
26  
27

28 **\*\*\*Table 1 About Here\*\*\***  
29  
30  
31

32 Correlation analyses were used to explore potential associations between participants'  
33  
34 forecast experience, self-assessed expertise and their ratings of importance for each factor, Forecast  
35  
36 experience was measured by the longest time (in years) the participants reported to be either making  
37  
38 their own forecasts or using others' forecasts. For the association between forecast experience and  
39  
40 importance rankings, none of the Spearman correlation coefficients between the pairs was found to  
41  
42 be significant (all  $p > .05$ ). It seems that the length of experience with making/using forecasts isn't  
43  
44 necessarily related to how important people believe certain factors are as determinants of trust. To  
45  
46 investigate further the existence of any association, the forecast experience was then categorized into  
47  
48 two groups ('moderate-experience' group – 1 to 9 years of forecast experience; 'high experience'  
49  
50 group –  $\geq 10$  years of forecast experience) and was tabulated against the percentages of high  
51  
52 importance ratings (aggregated across ratings of 4:very important and 5:extremely important) given  
53  
54 for each factor. Table 2 depicts these results.  
55  
56  
57  
58  
59  
60

**\*\*\*Table 2 About Here\*\*\***

The percentages presented in Table 2 also reinforce the finding that there appears to be no association between years of forecast experience and the importance people attribute to various factors as determinants of trust.

In terms of the association between self-assessed expertise and importance of factors, Spearman correlations showed that self-assessed level of knowledge/expertise was significantly related to the importance given to (i) knowledge about the statistical techniques used to generate forecasts ( $p = 0.001$ ), and (ii) the forecast format (point forecasts, interval forecasts, etc.) ( $p = 0.025$ ). To shed more light on this association, a similar analysis to the one presented in Table 2 was performed. The self-assessed forecast expertise was categorized into two groups ('moderate-expertise' group – ratings of 1, 2 and 3 ; the 'high-expertise' group – ratings of 4 and 5) and was tabulated against the percentages of high importance ratings (ratings of 4 and 5) given for each factor. These results are displayed in Table 3.

**\*\*\*Table 3 About Here\*\*\***

The correlation analysis and the scores presented in Table 3 suggest that the forecasters who believe they have higher levels of expertise/knowledge give more importance to knowledge of statistical techniques used to generate the forecasts than those with moderate self-assessed expertise. There appear to be no significant differences for any of the other items (all  $p > .05$ ).

In the next step of analysis, a principal axis factor analysis was conducted on the 15 features (excluding the last open-ended items) – i.e., importance ratings, that may affect a decision maker's trust in a given forecast. The chosen rotation method was the oblique rotation (direct oblimin) in order to accommodate for the case that extracted factors may not be independent and may correlate with each other. The Kaiser-Meyer-Olkin measure (Kaiser, 1970) designated that the sample was adequate

1  
2  
3 for the analysis, KMO = 0.765 (middling to meritorious according to Hutcheson & Sofroniou, 1999).  
4  
5 Bartlett's test of sphericity (Bartlett, 1950) also showed that the original correlation matrix is  
6  
7 significantly different from an identity matrix ( $p < 0.0001$ ) further indicating the sampling adequacy.  
8  
9

10 An inspection of the scree plot (given in Figure 1) has revealed that inflection occurred  
11  
12 between 3 to 5 factors. In agreement with this, Kaiser's criterion (Kaiser, 1960) also designated that  
13  
14 there were four factors with eigenvalues strictly larger than 1.00 and a fifth factor just on the border  
15  
16 with an eigenvalue of exactly 1.00 (1.005 to be precise). Therefore, for brevity, it was chosen to retain  
17  
18 four factors in the analysis. These four factors together explained 59.98% of the total variation in the  
19  
20 data. The loadings of these factors after the rotation are exhibited in Table 4.  
21  
22  
23  
24  
25  
26  
27

28 \*\*\*Figure 1 About Here\*\*\*

33  
34  
35  
36  
37  
38

39 This loading structure suggests that trust placed in a forecast seem to depend on four factors.  
40  
41 Factor 1 represents the **forecast bundle**, i.e., supportive features and tools provided in accompaniment  
42  
43 along with forecasts. As such, items loading high on this factor include scenarios, explanations, graphic  
44  
45 tools etc. Factor 2 can be interpreted as **forecaster competence**, i.e., perceived expertise and past  
46  
47 experience of the decision maker with the people who generate the forecasts and their knowledge  
48  
49 about the data used in the generation of forecasts. Factor 3 represents whether forecasts are  
50  
51 generated by a consensus or more than one forecaster and with multiple methods. This factor thus  
52  
53 refers to forecast **combination**. Lastly, Factor 4 designates the **knowledge** of statistical techniques and  
54  
55 forecasting methods. Factor 1, the forecast bundle, averages an importance rating for trust in forecasts  
56  
57 of 3.71 ( $SD = .51$ ). Factor 2, forecaster competence, scores 3.96 ( $SD = 0.14$ ) and factor 3, combination,  
58  
59  
60

1  
2  
3 averages 4.05 ( $SD = .03$ ). Factor 4, knowledge scores 3.60 ( $SD = .92$ ). Factor 2 and 3 are the largest, but  
4  
5 are not significantly different from each other ( $t(133) = -.52, p = .606$ ). They are however, both larger  
6  
7 than factor 1 (both at  $t(133) = -3.99(f1-2); -5.23(f1-3), p < .001$ ), which in turn is not significantly  
8  
9 different from factor 4 ( $t(133) = 1.32, p = .189$ ).

10  
11  
12 To verify the choice of the rotation method (i.e. the oblique rotation), the factor correlation  
13  
14 matrix was produced. All the off-diagonal correlation numbers among the factors are found to be quite  
15  
16 large in this matrix, therefore the factors, supportively, cannot be assumed as independent.

17  
18  
19 Looking at the scores of the respondents (the last column in Table 1), we can observe high  
20  
21 overall ratings for the items that refer to the combination of forecasts. Thus, it seems that combining  
22  
23 forecasts (from different techniques or different judges) is important to the users of the forecast. The  
24  
25 two highest scoring items are “My knowledge about expertise of persons making the forecasts” and  
26  
27 “Explanations accompanying the forecasts are given”, with each having 81% of the scores being a 4 or  
28  
29 5 on the scale. On the other end of the spectrum, we find that consultation with the end user of the  
30  
31 forecast does not seem to matter. Surprisingly, less than 50% scored ‘knowledge of the statistical  
32  
33 method’ as being important to place their trust on forecasts.

34  
35  
36 The answers to the open-ended questions were analysed in an iterative process, where every  
37  
38 answer was coded according to a response category. These response categories were identified by  
39  
40 reading the comments and structuring groupings around the keywords raised in the comments to allow  
41  
42 for the identification of unexpected themes. For the first open-ended question, i.e., “trust in forecasts  
43  
44 means the following to me”, we identified the categories *support, trusting people, trusting statistics,*  
45  
46 *source credibility, risk, error, based on history and combination of methods.* The first two categories,  
47  
48 namely *support* and *trusting people* were mentioned 3 – 5 times as often as the other categories. First  
49  
50 and foremost, the most often used category shows that forecasts are seen as a form of *support*.  
51  
52 Importantly, this indicates that trust may serve as a factor in the acceptance of software forecasts,  
53  
54 without employing damaging adjustments. Participants often mention how trusting forecasts can  
55  
56 provide guidance in doing one’s work, planning a project, and having a reliable source to work with.  
57  
58  
59  
60

1  
2  
3 As one participant so eloquently put it, being able to trust your forecasts means “*a tree branch to hold*  
4 *on to in a stormy sea of uncertainty*”. It allows one to make plans for the future and shape strategies.  
5  
6  
7 Importantly, it means being able to make decisions based on the data that is received. The second  
8  
9  
10 distinct category is that of *trusting people*: trusting the forecast is most often perceived as trusting the  
11  
12 person behind the numbers, more so than trusting the underlying statistics: one person summarizes it  
13  
14 succinctly by stating that trusting forecasts means “*trusting other people's experience, data processing*  
15 *and related skills*”. Vital to the setup of this study is the confirmation by one participant that “*trusting*  
16 *forecasts means taking the forecasts made by others and using them in my analysis exactly as they're*  
17 *given or with very little adjustment*”. Indeed, it seems that trust has a direct impact on the level of  
18  
19 adjustment for the participants. Thus, it is important to look into the factors that can heighten trust in  
20  
21 forecasts, thereby heightening acceptance of the forecasts.  
22  
23  
24  
25  
26  
27

28 With regard to the second open ended question, i.e., “the following is required to  
29  
30 increase/boost/enhance my trust in forecasts”, the following categories were identified: *accuracy,*  
31 *appropriate data/parameters/methods, experience/expertise, source credibility, combination of*  
32 *methods, and explanations*. Three categories were more prominent than others: *accuracy, appropriate*  
33 *data/parameters/methods, and experience/expertise*. : First, a proven track record of accurate  
34  
35 forecasts is necessary to gain the trust of the forecast user. Most often mentioned is the accuracy of  
36  
37 the forecaster “*Forecaster has a high hit rate/accuracy*”, and “*It is important that the forecaster is an*  
38 *expert in what s/he is doing and communicates his/her info well*”. Notably, it is not just the hit rate or  
39  
40 accuracy that is vital in boosting trust. Communication seems to be a vital factor, as well as honesty.  
41  
42  
43 Second, the user wants to see that the appropriate data and methods have been used in creating the  
44  
45 forecast: “*Forecast should involve statistical procedures/analysis or based on a sound logical*  
46 *foundation*”. The method needs to be reliable, as well as the data. Again, communication plays a role:  
47  
48 “*Forecast methods and analysis used should also be shared along with the forecasts.*”. Third, the  
49  
50 experience and expertise of the forecaster who makes the forecast needs to be high: Boosting trust is  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

possibly by “an *increase of experience and expertise of forecasters*” and “*Increase in experience, comparisons of forecasts with realized values*”.

### Discussion

In this study, we set out to investigate the determinants of trust in forecasting. Using a forecasting survey, we found four factors that play a role. The first factor is the forecast bundle, i.e. supportive features and tools, such as explanations or graphical representations. As such, this result links back to the finding of Goodwin et al. (2013), who found explanations to have a significant effect on stated trust. In the more general advice taking literature we see reference to this finding as well: people take advice less because they do not know the rationale used by the advisor (Yaniv, 2004a, 2004b). As such, providing an explanation, a reasoning, behind the forecasts, should increase user’s acceptance of the forecast and lessen the judgmental adjustment. Gönül, Önkal, and Goodwin (2009) find confirmation of this in their study: one reason for ‘*not adjusting*’ reported to them by their respondents is that “the explanations provided with the acquired forecast are persuasive” (p. 28). Another reason cited by their respondents is “the presentation and the style of language used in the acquired forecasts are persuasive”, referring again to the supportive features of the forecast.

The second factor relates back to the competence of the forecaster (both the initial forecaster (be it human or algorithm) and the user of the forecast who can potentially adjust): what is their perceived experience and past expertise? This factor can be seen as the credibility of the forecaster. Credibility plays an important role in the trustworthiness of the advisor (Önkal et al., 2017). Sources who are seen as unbiased, objective and are well-known are motivation for not adjusting the forecast (Gönül et al., 2009). Additionally, if one feels that their own expertise outweighs that of the initial forecasters, this can be a sufficient reason to adjust (Gönül et al., 2009).

The third factor describes forecast combination, be it either a group of judgmental forecasters, or the combination of judgment and algorithms. Combining forecasts has long been known to outperform single method forecasts (Clemen, 1989), whether it is a combination of multiple judges

1  
2  
3 (Dalrymple, 1987; Mentzer & Cox, 1984), multiple algorithms (e.g., Makridakis, Hibon, & Moser, 1979)  
4  
5 or algorithms with judges (e.g., Blattberg & Hoch, 1990). Combining methods can reduce error as the  
6  
7 errors and potentials biases have a chance to average out.  
8

9  
10 The fourth and last factor refers to the knowledge of the decision maker on statistical  
11  
12 techniques and forecasting methods. Forecast training has the potential of future savings and process  
13  
14 improvement: Merrick, Hardin, and Walker (2006) found investments in forecast training to pay  
15  
16 themselves back quickly and many times over.  
17

### 18 *Practical implications, limitations and future research*

19  
20 This study suggests that there are a number of factors we can focus on to heighten trust in  
21  
22 forecasting, which can be used as a proxy for heightening acceptance of forecast advice, thereby  
23  
24 reducing harmful adjustments. While the large number of professional forecasters participating in the  
25  
26 survey is a main strength, it also brings limitations; e.g., the current sample does not allow comparisons  
27  
28 with non-experts. There are also potential limitations due to the validity and reliability of the survey  
29  
30 instrument, which may restrict generalizability of findings. This study was focused on professionals  
31  
32 with moderate to high knowledge of forecasting who had moderate to high experience in  
33  
34 using/making forecasts. Given that the participants were professionals with forecasting experience  
35  
36 (and not students or Amazon Mechanical Turk participants, for example) enhances the likelihood that  
37  
38 phrases like 'forecast format' are interpreted as intended. But still there could be unanticipated issues,  
39  
40 as common with all such surveys.  
41  
42  
43  
44

45  
46 Lee and See (2004) provide a number of recommendations to increase trust in automation,  
47  
48 which may be transferable to the world of forecasting: amongst others, showing past performance,  
49  
50 showing the process and results in a comprehensible manner and showing the purpose of the  
51  
52 automation and how it relates to the user's goals. This relates back to the concept of communication,  
53  
54 which was often mentioned in the open ended questions on how to improve trust in forecasts. Thus,  
55  
56 providing explanations and supporting tools, stressing the expertise of the initial forecaster, combining  
57  
58  
59  
60

1  
2  
3 forecasts and knowledge can all contribute to heightened trust in forecasting, less forecast  
4 adjustments and thus has the potential for improved forecasting accuracy.  
5  
6

7 Forecast support systems should be designed in a way to facilitate trust in forecasts by the  
8 user, as suggested by the first factor, the supportive bundle. Features should include graphical versus  
9 tabular representations and an option to provide explanations for forecasts. The latter will increase  
10 trust when data, forecasts and adjustments are shared amongst forecasters. When people do not have  
11 access to the rationale behind a forecast, they are more likely to adhere to their own judgment rather  
12 than trusting the forecast given to them (Yaniv, 2004b). Importantly, the third factor suggests that an  
13 option to combine forecasts is necessary when designing support systems: be it either different  
14 statistical methods or the combination of as statistical system and judgment. This combining of  
15 forecasts has long been known in research to outperform single forecasting methods (Fischer &  
16 Harvey, 1999; Goodwin, 2002). This study confirms that practitioners recognize the improved forecast  
17 accuracy from combining forecasts.  
18  
19  
20  
21  
22  
23  
24  
25  
26  
27  
28  
29  
30  
31

32 The second and fourth factor have implications for management practices such as hiring and  
33 team guidance. Hired forecasters will be trusted more by their colleagues if they have a proven track  
34 record and credibility. They will need to display the necessary forecasting knowledge and knowledge  
35 about the product/service if their forecasts are to be trusted and their forecasts not adjusted  
36 unnecessarily. At the same time, these external forecasters can effectively engage in forecast training  
37 sessions where the knowledge base of the resident forecasters and decision makers could be  
38 augmented. These efforts will all contribute to team building and synergy formation exercises directed  
39 towards future planning and strategy development. After all, future-focused management is a  
40 multiplayer effort and rests heavily on the shoulders of an effective team.  
41  
42  
43  
44  
45  
46  
47  
48  
49  
50  
51

52 A potential limitation where the second factor, forecaster competence, is concerned, is that  
53 people are generally not that good at assessing a forecaster's abilities (Gönül, Goodwin, & Önkül,  
54 2012). We are heavily influenced by one-time, salient occurrences: one big error in an otherwise good  
55 track record lowers our trust more than warranted – even more so for algorithms (Dietvorst et al.,  
56  
57  
58  
59  
60

1  
2  
3 2015; Önkal et al., 2009; Prahla & Van Swol, 2017), while one accurate forecast of an unexpected event  
4  
5 in the middle of a bad track record raises our expectations disproportionately (Denrell & Fang, 2010).  
6  
7 One can also question if trust really does counter algorithm aversion. While we can derive from the  
8  
9 forecasting literature and advice literature that this is probably the case, future research would benefit  
10  
11 from structurally testing this in an experimental setup. One could manipulate trust by providing  
12  
13 information on past performance or on the credibility of the source. Trust is an evolving concept rather  
14  
15 than a static one: being confronted with accuracy of subsequent forecasts will lead to calibration of  
16  
17 trust in the forecaster/algorithm (the agreement between the level of trust in automation and the  
18  
19 actual performance of the automation; Lee & See, 2004). Importantly, trust does not develop in itself:  
20  
21 it is an interplay between an individual's propensity to trust, experiences with the algorithm and the  
22  
23 wider context in which the forecasting occurs: trust is an attitude that evolves over time (Rempel,  
24  
25 Holmdes, & Zanna, 1985). A careful experimental paradigm should take this feedback loop into account  
26  
27 to dig into the true effects of trust on algorithm acceptance.

**Table 1. Mean scores and standard deviations for each factor, including comparisons with neutral midpoint=3**

**( df for all t-tests = 133)**

Factor	Mean	SD	t-value (test value = 3)	p-value (2-tailed)	Percentage of 4 and 5 ratings on all items
Explanations accompanying the forecasts are given	4.24	.91	15.60	< .001	81%
My knowledge about the expertise of the person(s) making the forecasts	4.11	.95	13.59	< .001	81%
Forecasts are elicited from more than one forecaster	4.08	.92	13.64	< .001	78%
Multiple techniques are used in generating forecasts	4.04	.98	12.20	< .001	78%
Consensus forecasts is given (by more than one forecaster)	4.02	.92	12.96	< .001	78%
My past experiences with the forecaster(s) making the forecasts	4.02	.99	11.93	< .001	75%
Presented forecasts are supported by scenarios	4.02	.86	13.72	< .001	73%
My knowledge about the data used to generate the forecasts	4.01	.98	11.98	< .001	75%
Information that the forecasts will be revised in known intervals	3.97	1.03	10.87	< .001	72%
Information about the person(s) making the forecasts	3.88	1.00	10.15	< .001	72%
My past experiences with technique(s) used to generate the forecasts	3.75	1.16	7.52	< .001	65%
Forecast format (point forecasts, interval forecasts, etc.)	3.63	1.02	7.23	< .001	57%
Forecasts are presented using graphic tools/plots	3.59	1.11	6.14	< .001	60%
Knowledge about the statistical techniques used to generate the forecasts	3.45	1.04	5.00	< .001	49%
Forecasts are prepared by consulting with me	2.81	1.21	-1.85	.067	30%

**Table 2. Percentages of high importance ratings (4 and 5) for each factor as determinant of trust : Breakdown across forecast experience (counts/category total in parenthesis)**

Percentage of 4 and 5 ratings on the factors	High Forecast Experience (>10 years)	Moderate Forecast Experience (1 to 9 years)	Is the difference significant?
Knowledge about the statistical techniques used to generate the forecasts	48.39% (30/62)	48.61% (35/72)	N.S.
Multiple techniques are used in generating forecasts	77.42% (48/62)	79.17% (57/72)	N.S.
My past experiences with technique(s) used to generate the forecasts	66.13% (41/62)	63.89% (46/72)	N.S.
Information about the person(s) making the forecasts	77.42% (48/62)	68.06% (49/72)	N.S.
Forecasts are elicited from more than one forecaster	82.26% (51/62)	75.00% (54/72)	N.S.
Consensus forecasts is given (by more than one forecaster)	77.42% (48/62)	79.17% (57/72)	N.S.
My past experiences with the forecaster(s) making the forecasts	74.19% (46/62)	75.00% (54/72)	N.S.
My knowledge about the expertise of the person(s) making the forecasts	80.65% (50/62)	81.94% (59/72)	N.S.
My knowledge about the data used to generate the forecasts	69.35% (43/62)	79.17% (57/72)	N.S.
Forecasts are prepared by consulting with me	33.87% (21/62)	26.39% (19/72)	N.S.
Explanations accompanying the forecasts are given	83.87% (52/62)	79.17% (57/72)	N.S.
Forecasts are presented using graphic tools/plots	58.06% (44/62)	61.11% (44/72)	N.S.
Forecast format (point forecasts, interval forecasts, etc.)	50.00% (31/62)	63.89% (46/72)	N.S.
Information that the forecasts will be revised in known intervals	72.58% (45/62)	70.83% (51/72)	N.S.
Presented forecasts are supported by scenarios	74.19% (46/62)	72.22% (52/72)	N.S.

**Table 3. Percentages of high importance ratings (4 and 5) for each factor as determinant of trust: Breakdown across self-assessed expertise (counts/category total in parenthesis)**

Percentage of 4 and 5 ratings on the factors	High Self-Assessed Expertise (Ratings of 4 and 5)	Moderate Self-Assessed Expertise (Ratings of 1,2 and 3)	Is the difference significant?
Knowledge about the statistical techniques used to generate the forecasts	68.42% (26/38)	40.63% (39/96)	Fisher's exact p = 0.004
Multiple techniques are used in generating forecasts	86.84% (33/38)	75.00% (72/96)	N.S.
My past experiences with technique(s) used to generate the forecasts	65.79% (25/38)	64.58% (62/96)	N.S.
Information about the person(s) making the forecasts	71.05% (27/38)	72.92% (70/96)	N.S.
Forecasts are elicited from more than one forecaster	73.68% (28/38)	80.21% (77/96)	N.S.
Consensus forecasts is given (by more than one forecaster)	76.32% (29/38)	79.17% (76/96)	N.S.
My past experiences with the forecaster(s) making the forecasts	78.95% (30/38)	72.92% (70/96)	N.S.
My knowledge about the expertise of the person(s) making the forecasts	86.84% (33/38)	79.17% (76/96)	N.S.
My knowledge about the data used to generate the forecasts	78.95% (30/38)	72.92% (70/96)	N.S.
Forecasts are prepared by consulting with me	34.21% (13/38)	28.13% (27/96)	N.S.
Explanations accompanying the forecasts are given	76.32% (29/38)	83.33% (80/96)	N.S.
Forecasts are presented using graphic tools/plots	60.53% (23/38)	59.38% (57/96)	N.S.
Forecast format (point forecasts, interval forecasts, etc.)	60.53% (23/38)	56.25% (54/96)	N.S.
Information that the forecasts will be revised in known intervals	76.32% (29/38)	69.79% (67/96)	N.S.
Presented forecasts are supported by scenarios	68.42% (26/38)	75.00% (72/96)	N.S.

**Table 4. Factor loadings (pattern matrix) of features that affect trust in forecasts**

FEATURES THAT AFFECT TRUST IN FORECASTS	ROTATED FACTOR LOADINGS			
	Factor 1	Factor 2	Factor 3	Factor 4
Presented forecasts are supported by scenarios	<b>0.715</b>	0.008	-0.140	-0.119
Forecasts are presented using graphic tools	<b>0.641</b>	0.143	-0.161	-0.006
Forecast format	<b>0.559</b>	-0.171	0.125	0.150
Info that forecasts will be revised in known intervals	<b>0.518</b>	-0.161	0.102	0.046
Explanations accompanying the forecasts are given	<b>0.401</b>	-0.216	-0.096	-0.071
Forecasts are prepared by consulting with me	<b>0.394</b>	0.099	-0.008	0.044
My knowledge about expertise of persons making the forecasts	-0.128	<b>-0.810</b>	-0.102	0.108
My past experiences with the forecasters making the forecasts	0.081	<b>-0.773</b>	-0.018	-0.171
Information about the person(s) making the forecasts	0.032	<b>-0.671</b>	-0.062	-0.018
My knowledge about the data used to generate the forecasts	0.060	<b>-0.588</b>	0.003	0.235
My past experiences with technique(s) used to generate the forecasts	0.010	<b>-0.379</b>	-0.045	<b>0.314</b>
Consensus forecasts are given by the forecasters	0.029	-0.076	<b>-0.748</b>	0.051
Forecasts are elicited from more than one forecaster	-0.024	-0.046	<b>-0.695</b>	-0.033
Multiple techniques are used in generating forecasts	<b>0.325</b>	-0.004	<b>-0.382</b>	0.188
Knowledge about the statistical techniques used to generate the forecasts	0.051	0.013	-0.043	<b>0.821</b>
Eigenvalues	4.553	2.033	1.336	1.075
% of total variance explained	30.36	13.56	8.91	7.16

*Note.* Factor loadings over 0.30 appear in bold.
