Gout is one of the most common metabolic disorders in human. Previous studies have shown that the disease activity is closely associated with sympathetic nervous system (SNS). α_{2B} -adrenergic receptor ($\alpha_{2B}AR$), a subtype of α_2 adrenergic receptor, plays a critical role in many diseases. However, the role of $\alpha_{2B}AR$ in the pathogenesis of gout remains unclear. Here, we assessed the role of $\alpha_{2B}AR$ in the monosodium urate (MSU) crystals-induced peritonitis that mimics human gout by using the $\alpha_{2B}AR$ -overexpressing mice ($\alpha_{2B}AR$ -Tg). We found that the number of recruited neutrophils was significantly increased in the $\alpha_{2B}AR$ -Tg mice after MSU treatment, when compared with wild type mice. In contrast, the number of macrophages was not changed. Importantly, there is no difference in the IL-1 β levels and caspase-1 activity between wild type and $\alpha_{2B}AR$ -Tg mice in the gout animal model. Notably, the enhanced neutrophil migration in $\alpha_{2B}AR$ -Tg mice was dependent on the $\alpha_{2B}AR$ overexpression in neutrophils, but not resulted from other tissues or cells with $\alpha_{2B}AR$ overexpression. In conclusion, our data provide a direct evidence that $\alpha_{2B}AR$ plays a critical role in neutrophil migration and MSU-induced inflammation.

Keywords: gout, adrenergic receptor, neutrophil, monosodium urate, inflammation

INTRODUCTION

The cross-talk between the sympathetic nervous system (SNS) and immune system has gained increasing attentions through catecholamines hormone (1–3). Catecholamines exert their physiological effects by binding adrenergic receptors, which are a class of G protein-coupled receptors. There are two main groups of adrenoceptors, α and β , with 9 subtypes in total (4). An increased production of endogenous catecholamines epinephrine and norepinephrine can be observed in a status of anxiety, pathogenic challenge, and pain (5). It has been demonstrated recently that SNS play an important role in the induction of stress-induced pro-inflammatory cytokines, such as IL-1 β induction (6). Consistent with this, the baseline epinephrine in healthy humans is inversely correlated with pro-inflammatory cytokine levels and positively with anti-inflammatory cytokine productions (7). In addition, SNS have also been implicated in chronic intestinal inflammation, multiple sclerosis, and rheumatoid arthritis through T cell immune responses (8–11).

Accumulating data indicate that SNS plays a critical role in the control of metabolic and cardiovascular homeostasis. Both experimental and clinical studies have shown that the changes of catecholamines in plasma and tissue were associated with the pathogenesis of metabolic and cardiovascular diseases (12, 13). Gout is one of the most common human metabolic diseases characterized by sudden pain and swelling in the joints. The abnormal uric acid (UA) metabolism results in monosodium urate (MSU) crystal formation in the joint and periarticular tissues, which activates the resident macrophage to produce IL-1 β , a crucial inflammatory cytokines in the pathogenesis of gout (14, 15). Increasing evidences have demonstrated that $\alpha_2\text{AR}$ stimulation promotes cytokine production. It has been shown that the $\alpha_2\text{AR}$ was required for norepinephrine-induced DC endocytosis through modulating the PI3K and ERK1/2 signaling pathway in DCs (16). The $\alpha_2\text{AR}$ agonist dexmedetomidine can decrease the IL-1 β -induced IL-6 production in glioma cells (17). $\alpha_2\text{AR}$ s include three highly homologous subtypes, $\alpha_{2A}\text{AR}$, $\alpha_{2B}\text{AR}$, and $\alpha_{2C}\text{AR}$. However, the modulation of $\alpha_{2B}\text{AR}$ on the pathogenesis of gout remains elusive.

Here, we addressed the role of $\alpha_{2B}\text{AR}$ in the pathogenesis of MSU-induced inflammation by using the $\alpha_{2B}\text{AR}$ over-expressing transgenic mice ($\alpha_{2B}\text{AR-Tg}$). We found that the MSU-induced inflammation was exacerbated in $\alpha_{2B}\text{AR-Tg}$ mice, characterized by increased neutrophils infiltration. In

consistency, neutrophils with $\alpha_{2B}\text{AR}$ over-expression also displayed an enhanced migratory ability in *in vitro* experiments. In contrast, the number of macrophage and IL-1 β levels were not altered. In conclusion, $\alpha_{2B}\text{AR}$ plays an important role in MSU-induced inflammation by enhancing the migration of neutrophils. Therefore, $\alpha_{2B}\text{AR}$ may serve as a promising therapeutic target for gout.

MATERIALS AND METHODS

Animals

FVB/NJ mice (wild-type, Wt) and $\alpha_{2B}\text{AR}$ transgenic mice ($\alpha_{2B}\text{AR-Tg}$) in FVB/NJ background were purchased from the Jackson Laboratory. The mice were housed in the specific pathogen-free animal facility at the Case Western Reserve University. All experimental procedures involving mice were approved by the Institutional Animal Care and Use Committees (IACUCs) at the Case Western Reserve University and Xiamen University.

Establishment of Acute Gout Animal Model

Male mice (6–8 weeks old) were administered an intraperitoneal (IP) injection of 3 mg MSU (Invivogen, US). After 16 h, the peritoneal exudate cells (PECs) and lavage fluids were harvested and subjected to flow cytometry analysis and cytokine assay.

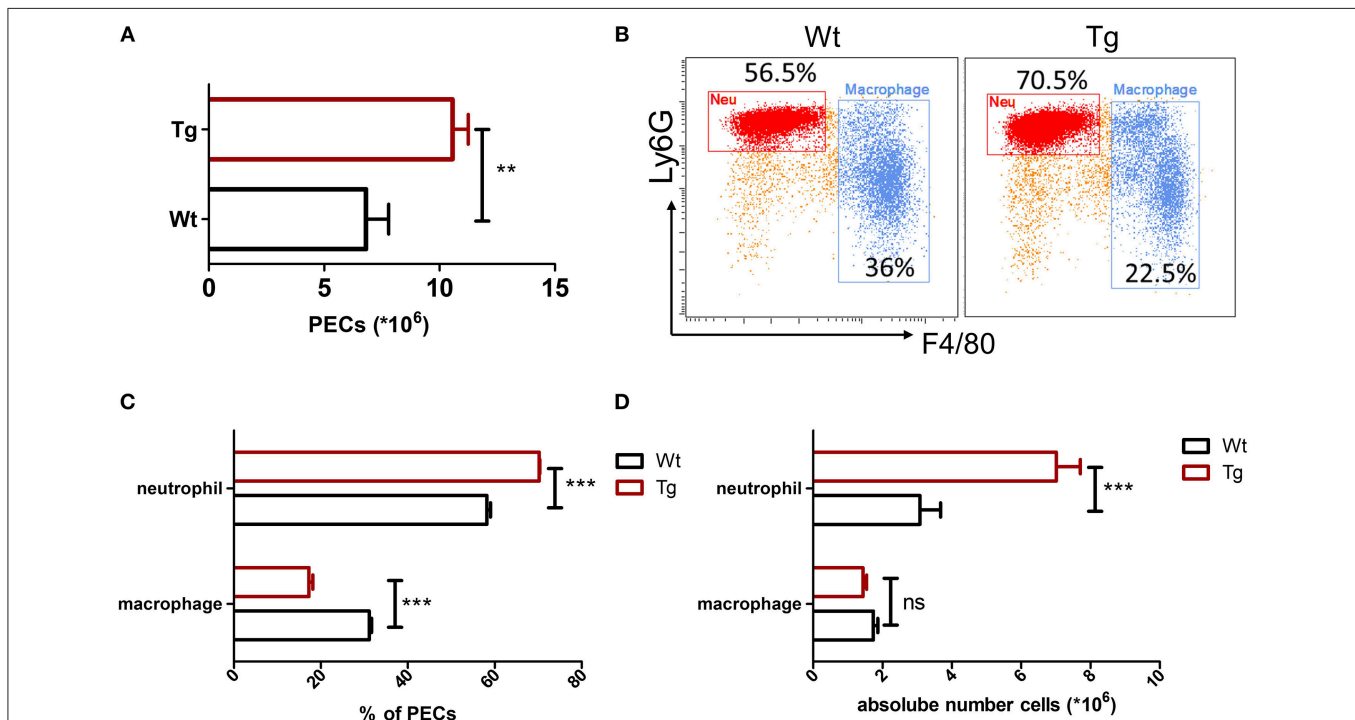

FIGURE 1 | Increased neutrophil recruitment in $\alpha_{2B}\text{AR-Tg}$ mice after MSU stimulation. Wt and $\alpha_{2B}\text{AR-Tg}$ mice were treated with MSU to induce peritonitis. After 6 h, the total PECs were harvested. **(A)** Quantitative analysis of total number of PECs. **(B)** The PECs were stained with anti-CD11b, anti-F4/80, and anti-Ly6G antibodies. CD11b⁺ cells were gated for the analysis of macrophage (CD11b⁺Ly6G⁻F4/80⁺) and neutrophil (CD11b⁺Ly6G⁺F4/80⁻). Representative images were shown. **(C)** Statistical bar graph showing the percentages of macrophages and neutrophils in total CD11b⁺ cells. **(D)** The absolute numbers of neutrophils and macrophages in PECs. Data are represented as mean \pm SEM ($n = 6-8/\text{group}$). The results shown are from one of three independent experiments. ** $p < 0.01$, *** $p < 0.001$. ns, not significant.

Flow Cytometry Analysis

The peritoneal exudate cells (PECs) were incubated with the fluorescent-conjugated monoclonal antibodies in the staining buffer. Antibodies used for flow cytometry are as follows, FITC anti-mouse F4/80, PE anti-mouse CD11b and PE/Cy7 anti-mouse Ly6G. All antibodies are purchased from Biolegend (San Diego, CA, US). Caspase 1 activity were determined by FAM-FLICA Caspase Assay Kits (Immunochemistry Technologies, Bloomington, MN, USA) according to the manufacturer's instructions through flow cytometry analysis.

Mouse Bone Marrow-Derived Macrophage Generation

Bone marrow-derived macrophages (BMMs) were generated from the bone marrow cells as described previously (18). Briefly, bone marrow cells isolated from the animals were seeded at the concentration of 1×10^6 /ml cells and cultured in the presence of M-CSF (20 ng/ml) (Peprotech, US) for 7 days. The supernatant was replaced every 2 days. Adherent BMMs were harvested at day 7 for further study.

Quantitative Real Time RT-PCR

Total RNA was extracted from PECs by TRIzol[®] Reagent (Invitrogen, Carlsbad, CA) as instructed. Reverse transcription

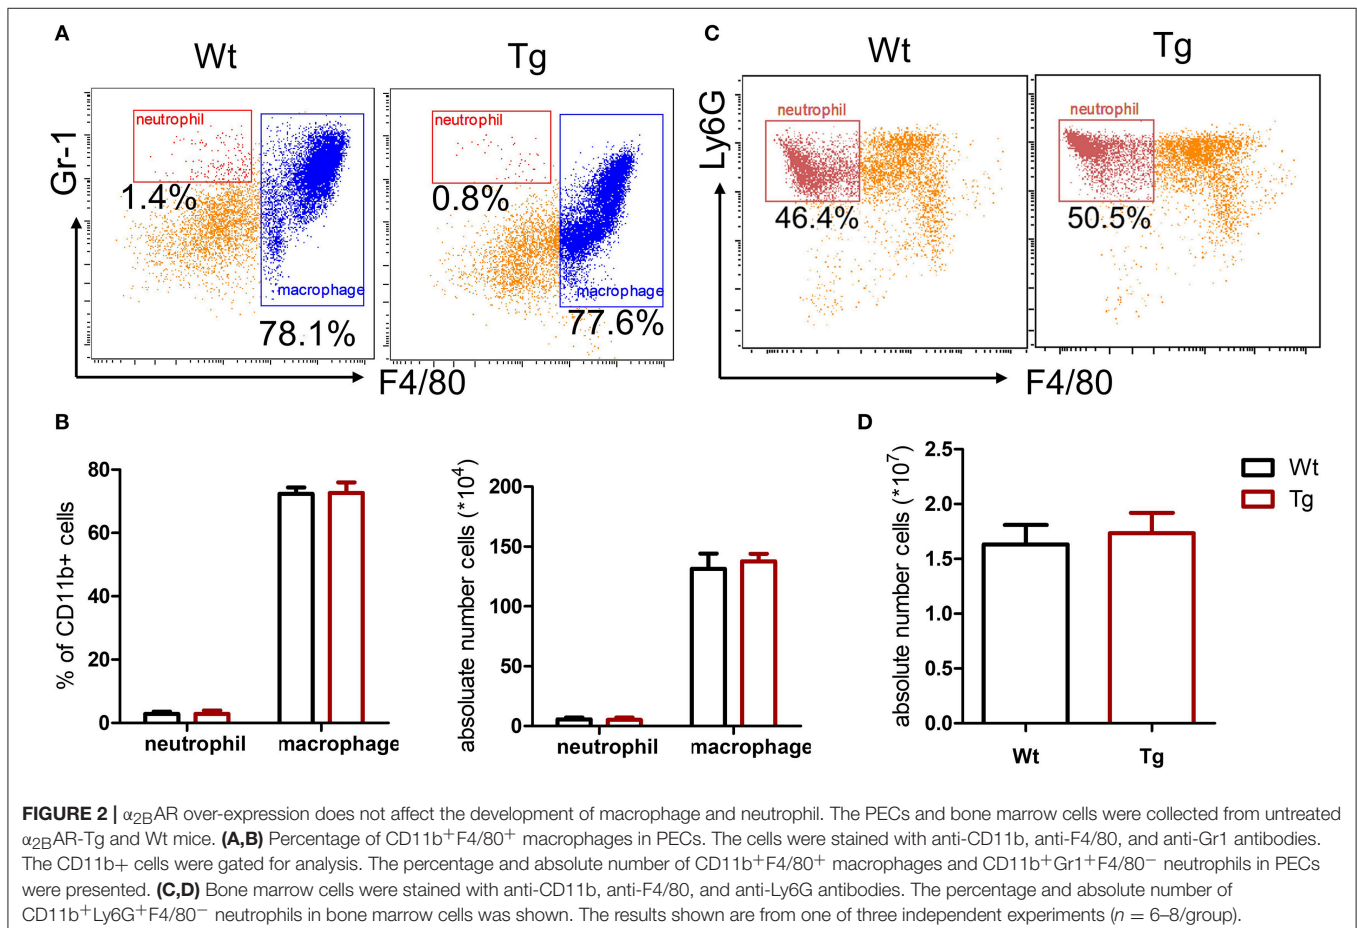

of total RNA was performed using cDNA synthesis kit (ABI, ON, Canada). The primers for β -actin, IL-1 β , MIP-2, NLRP3, and α_{2B} AR gene are listed below. mip-2, forward: TCA ATG CCT GAA GAC CCT G, reverse: CCT TGA GAG TGG CTA TGA CTT C; adra2b, forward: CTG GGC TAT TGG TAC TTC TGG, reverse: AGT TGT ACT CCA ATG CTC GG; β -actin, forward: ACC TTC TAC AAT GAG CTG CG, reverse: CTG GAT GGC TAC GTA CAT GG; IL-1 β , forward, ACG GAC CCC AAA AGA TGA AG, reverse: TTC TCC ACA GCC ACA ATG AG; nlrp3, forward: CTC CAA CCA TTC TCT GAC CAG, reverse: ACA GAT TGA AGT AAG GCC GG. The expression of target genes was normalized to β -actin.

ELISA (Enzyme-Linked Immunosorbent Assay)

The concentration of IL-1 β in the peritoneal lavage fluid or bone marrow macrophage culture supernatant was determined by an ELISA Kit (R&D, Minneapolis, MN, US) according to the Manufacturer's instruction.

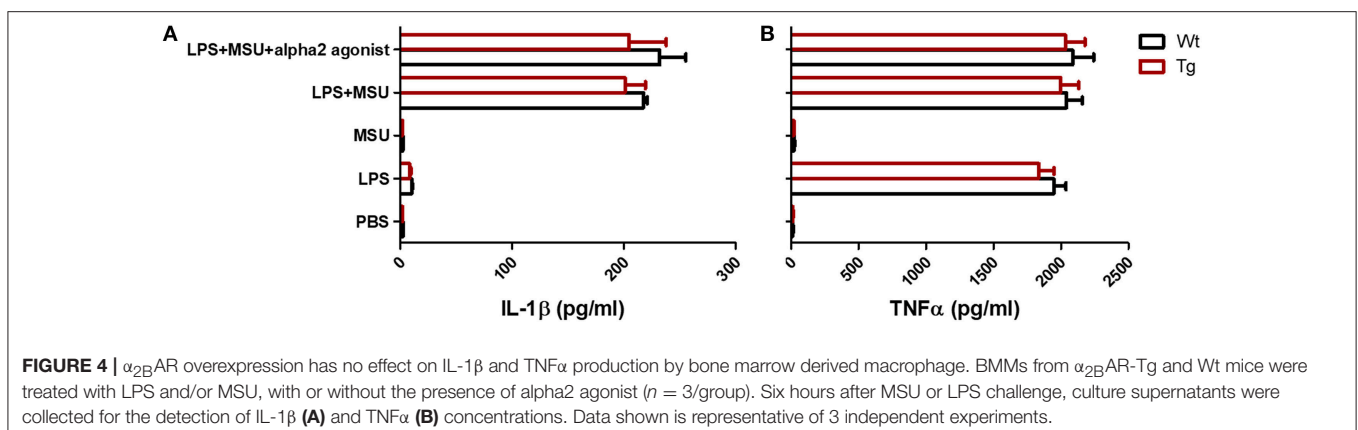

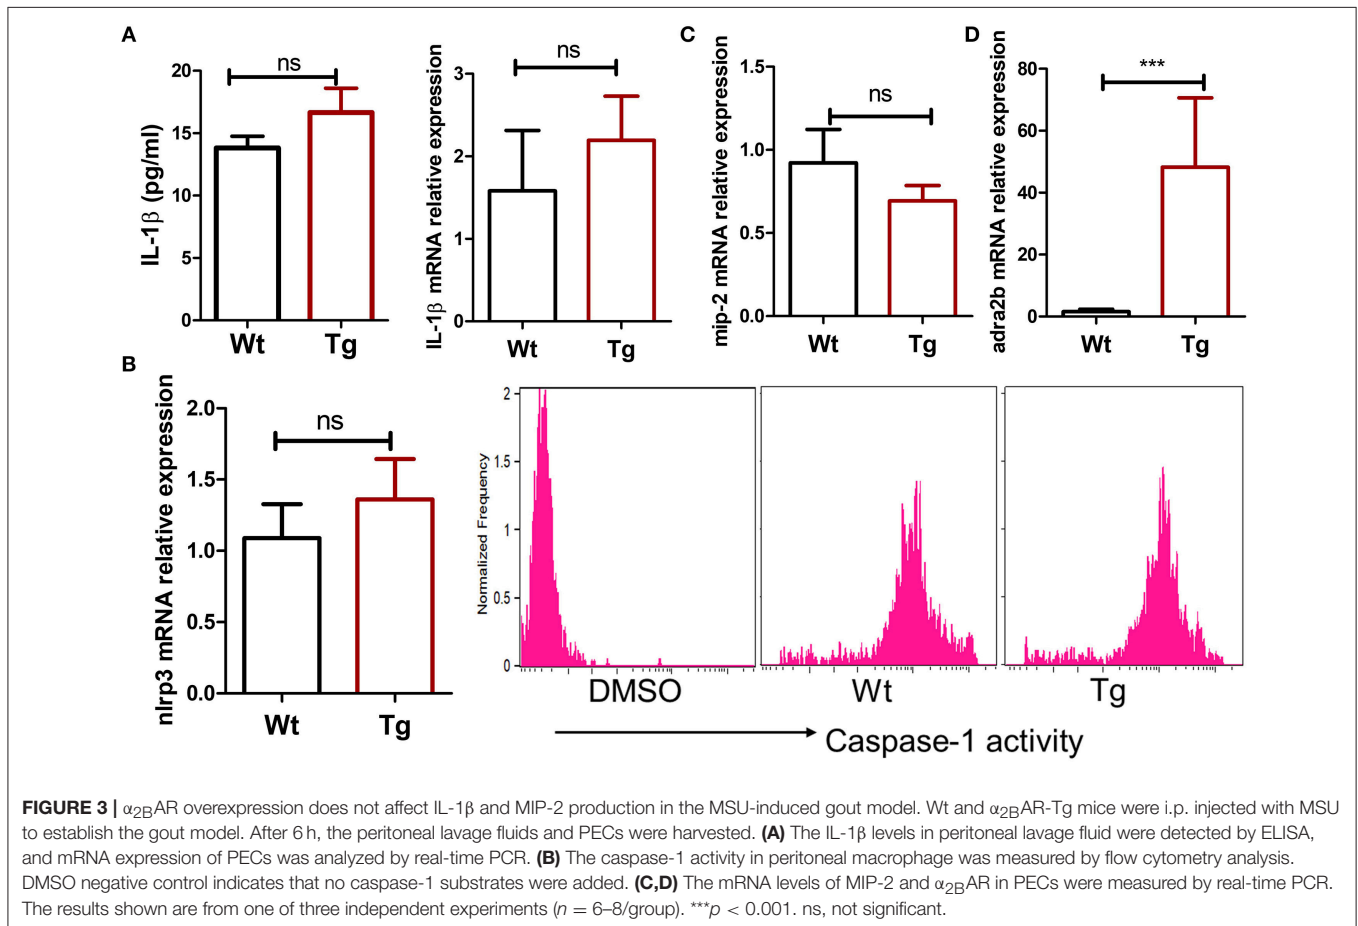

Neutrophil Migration Assay

Bone marrow neutrophils were isolated from Wt and α_{2B} AR-Tg mice using a MojoSortTM Mouse Neutrophil Isolation Kit (Biolegend, US). The isolated α_{2B} AR-Tg and Wt neutrophils

were stained with CellTrace™ Violet (V440) or CellTrace™ CFSE, respectively. Labeled cells were mixed at the ratio of 1:1 and then adoptively transferred into MSU-pretreated (3 mg/per mouse) Wt or $\alpha_2\text{B}$ AR-Tg mice. Splenocytes and PECs were harvested after 6h. The ratio and numbers of Wt (CFSE) and $\alpha_2\text{B}$ AR-Tg (V440) cells in the spleen and peritoneal fluid were determined by flow cytometry. For the *in vitro* neutrophil migration, the mixed neutrophils in Dulbecco modified Eagle medium with 10% Fetal Bovine

Serum were placed in the insert of a 6- μm Transwell® plate (Thermo Scientific) at the concentration of 1×10^6 cells/mL (100 μl /well). The lower chamber contained 600 μl Dulbecco modified Eagle medium with 10% Fetal Bovine Serum and MIP-2(200 ng/ml, PeproTech). After incubation for 4h in 37°C, the cells in the insert and bottom wells were collected and the ratio of Wt (CFSE) vs. $\alpha_2\text{B}$ AR-Tg (V440) cells were detected by fluorescence microscope and flow cytometry.

Statistical Analysis

Data are presented as mean \pm SEM. Group comparisons were performed using Student's *t*-test by GraphPad Prism software. *p*-values (two-tailed) below 0.05 were considered as statistically significant.

RESULTS

Neutrophil Recruitment in $\alpha_2\text{B}$ AR-Tg Mice Is Enhanced in Gout

Recent studies have shown a cross-communication between $\alpha_2\text{AR}$ and innate immune response (3), while the role and mechanism of $\alpha_2\text{B}$ AR subtype in the pathogenesis of gout are not clear. In this study, we first assessed the role of $\alpha_2\text{B}$ AR in MSU-induced peritonitis, a mouse model of gout. At 6 h after MSU challenge, the total PECs were harvested for the flow cytometric analysis. Compared with the wild-type mice (Wt), $\alpha_2\text{B}$ AR-Tg mice displayed a markedly elevated number of inflammatory cells in the peritoneal cavity (Figure 1A). The proportion of neutrophils, defined as $\text{CD11b}^+\text{Ly6G}^+\text{F4/80}^-$ cells, was significantly increased in the peritoneal cavity of $\alpha_2\text{B}$ AR-Tg mice. Conversely, a decreased proportion of macrophage ($\text{CD11b}^+\text{F4/80}^+$) was observed (Figures 1B,C). To further confirm the role of $\alpha_2\text{B}$ AR on MSU-induced neutrophil and macrophage infiltration, the absolute number of neutrophils and macrophage in the peritoneal cavity were also calculated. The absolute number of neutrophils was considerably

increased in $\alpha_2\text{B}$ AR-Tg mice, while the absolute numbers of macrophages were similar in the Wt and $\alpha_2\text{B}$ AR-Tg mice (Figure 1D). Furthermore, there was no differences in the frequency of macrophage and neutrophil in the peritoneal cavity (Figures 2A,B) and bone marrow (Figures 2C,D) between the $\alpha_2\text{B}$ AR-Tg and Wt mice without MSU treatment. Collectively, these data demonstrated that $\alpha_2\text{B}$ AR overexpression promoted the development of MSU-induced inflammation.

$\alpha_2\text{B}$ AR Does Not Affect MSU-Stimulated IL-1 β Production

MSU crystals can be phagocytosed by macrophages, leading to the release of pro-inflammatory cytokines such as IL-1 β , TNF α , and IL-6. Recent studies have suggested that IL-1 β produced by macrophage is a key inflammatory mediator in MSU crystal-induced inflammation. Massive neutrophil infiltration induced by MSU was eliminated in IL-1 receptor knockout mice (14). Since we did not observe a change in the absolute number of macrophages in $\alpha_2\text{B}$ AR-Tg mice after MSU treatment, we next examine the ability of macrophages to produce IL-1 β . To explore whether the increased neutrophil recruitment in MSU-treated $\alpha_2\text{B}$ AR-Tg mice is correlated with IL-1 β expression, we analyzed the IL-1 β levels of peritoneal lavage fluid from $\alpha_2\text{B}$ AR-Tg mice and Wt mice treated with MSU. Unexpectedly, there was no significant difference in IL-1 β production between $\alpha_2\text{B}$ AR-Tg mice and Wt mice (Figure 3A). The maturation of active IL-1 β requires inflammasome activation (19). In consistency with

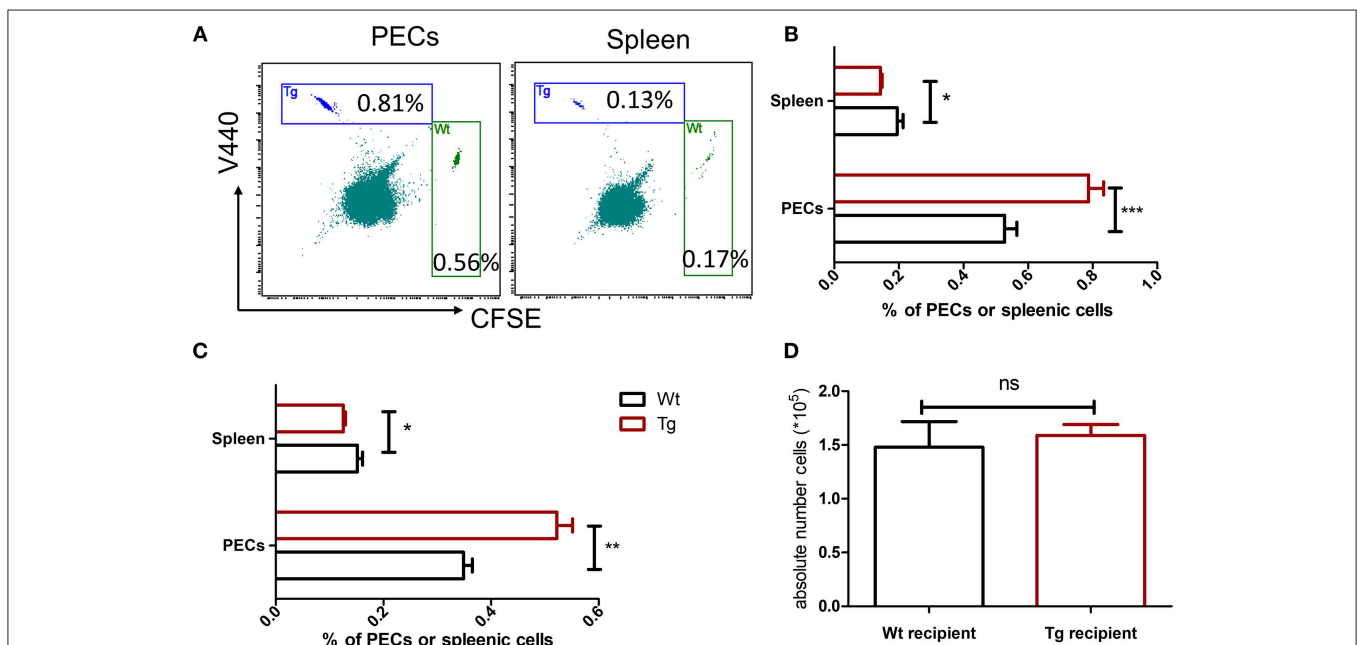

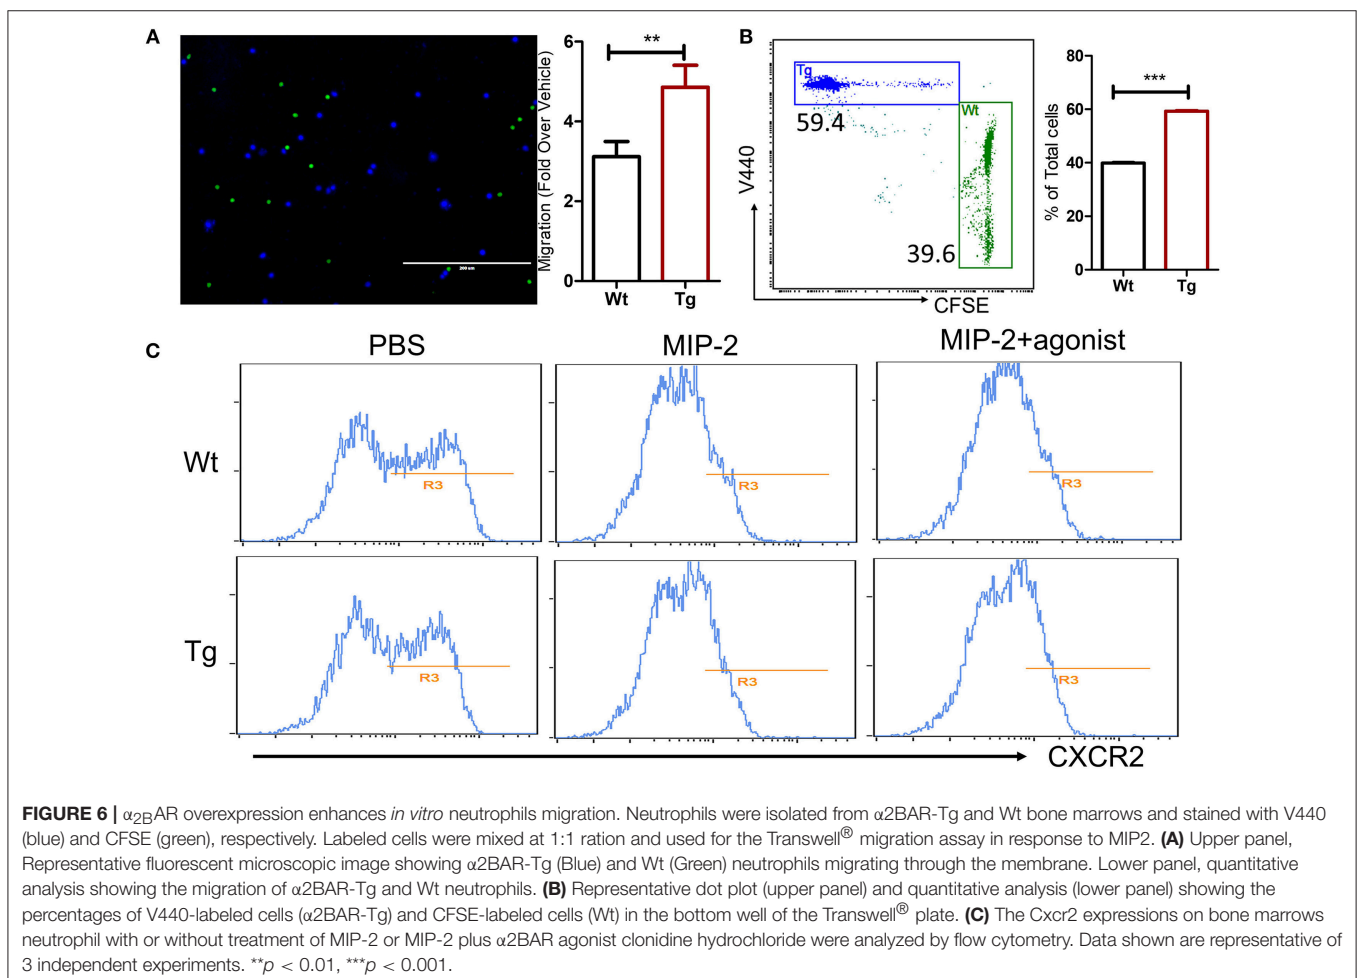

FIGURE 5 | $\alpha_2\text{B}$ AR enhances neutrophil recruitment in MSU-stimulated inflammation. Bone marrow neutrophils from $\alpha_2\text{B}$ AR-Tg or Wt mice were stained with V440 and CFSE, respectively. Cells were then mixed at 1:1 ration, followed by i.v. injection into MSU-treated Wt mice (A,B) or $\alpha_2\text{B}$ AR-Tg mice (C). Six hours after MSU challenge, the PECs and spleen were harvested. (A) Representative flow cytometry analysis of neutrophil proportion in the PECs and splenic cells from MSU-treated Wt mice. (B,C) Percentages of neutrophils in PECs and spleen from MSU-treated Wt (B) and $\alpha_2\text{B}$ AR-Tg mice (C) were analyzed. (D) The peritoneal fluid was collected from Wt and $\alpha_2\text{B}$ AR-Tg recipients and the absolute number of adoptively transferred neutrophils were analyzed. Data shown are representative of 3 independent experiments ($n = 5/\text{group}$). * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$. ns, not significant.

the result of IL-1 β , $\alpha_2\text{BAR}$ overexpression did not change the NLRP3 expression and caspase-1 activity (Figure 3B). Actually, a similar expression of MIP-2, the important chemokine of neutrophil, was observed in Tg and Wt mice (Figure 3C). Notably, the $\alpha_2\text{BAR}$ expression of PECs was still higher in Tg mice than Wt mice after MSU challenge (Figure 3D). Next, we further investigated the effect of $\alpha_2\text{BAR}$ overexpression on IL-1 β production by macrophages in an *in vitro* experiment. In accordance with the *in vivo* findings, there was no difference in IL-1 β expression between $\alpha_2\text{BAR}$ -Tg and Wt BMMs (Figure 4A). In addition, the production of TNF α was also not affected by $\alpha_2\text{BAR}$ overexpression (Figure 4B). Taken together, these results indicated that there is no significant difference in IL-1 β production between $\alpha_2\text{BAR}$ -Tg mice and Wt mice. The increased number of neutrophils in the peritoneal cavity of $\alpha_2\text{BAR}$ -Tg mice may be a result of enhanced migration potential of neutrophils.

$\alpha_2\text{BAR}$ Overexpression Enhances Neutrophil Recruitment in a Mouse Model of Gout

To test whether the expression of $\alpha_2\text{BAR}$ on neutrophils regulates their migration, neutrophils isolated from $\alpha_2\text{BAR}$ -Tg

mice and Wt mice were labeled with different fluorescent dyes, respectively, followed by adoptive transfer into MSU-treated recipients. Equal numbers of V440-labeled $\alpha_2\text{BAR}$ -Tg neutrophils and CFSE-labeled Wt neutrophils were mixed and transferred into MSU-pretreated Wt mice. The PECs and splenocytes were harvested for the flow cytometric detection of V440-labeled $\alpha_2\text{BAR}$ -Tg and CFSE-labeled Wt neutrophils (Figure 5A). As expected, there were more $\alpha_2\text{BAR}$ -Tg neutrophils in the peritoneal cavity of the Wt recipients (Figure 5B). Moreover, $\alpha_2\text{BAR}$ -Tg neutrophils had an enhanced migration into the peritoneal cavity of MSU-treated $\alpha_2\text{BAR}$ -Tg recipients (Figure 5C). To further examine if the expression of $\alpha_2\text{BAR}$ in other tissues or cell types would affect neutrophil recruitment, we compared the migration of neutrophils into the peritoneal cavity of Wt vs. $\alpha_2\text{BAR}$ -Tg mice. We found the absolute number of neutrophils migrated to the peritoneal cavity of $\alpha_2\text{BAR}$ -Tg recipients was similar to that migrated into the peritoneal cavity of Wt recipients (Figure 5D), suggesting the overexpression of $\alpha_2\text{BAR}$ in other tissue or cell types did not affect the migratory ability of neutrophils. These data indicated that $\alpha_2\text{BAR}$ overexpression on neutrophils promotes its migratory ability.

α_2 BAR Overexpression Enhances the Migratory Capacity of Neutrophil *in vitro*

Because lots of factors can affect the neutrophil migration during the development of inflammation *in vivo*, the migratory capacity of α_2 BAR-Tg neutrophils was further investigated *in vitro* to exclude the microenvironmental factors. CXCR2 has a central role in the recruitment of neutrophils. We next examined the migration of the neutrophils toward CXCR2 ligand MIP-2. In consistency with the *in vivo* result, α_2 BAR overexpression on neutrophils increased their chemotaxis toward MIP-2 in the *in vitro* Transwell[®] assay (Figures 6A,B). We next examined the expression level of CXCR2 on neutrophils. No significant difference in CXCR2 expressions on bone marrow neutrophils was observed between α_2 BAR-Tg and Wt mice (Figure 6C). It has been shown that the binding with MIP-2 induces CXCR2 internalization. In consistency, we here also observed a decreased expression on neutrophil surface after MIP-2 treatment in both Wt and Tg mice. There was also no significant difference in cell surface expression of CXCR2 after MIP-2 stimulation, suggesting that α_2 BAR does not affect CXCR2 internalization (Figure 6C). In addition, α_2 BAR activation by agonist clonidine hydrochloride did not affect the expression of CXCR2, further suggesting that the enhanced neutrophil migration was independent of CXCR2 expression (Figure 6C). These data strongly suggested that the increased migratory ability of α_2 BAR-Tg neutrophils was independent of CXCR2.

DISCUSSION

In this study, we showed that MSU-induced inflammation was enhanced in α_2 BAR-Tg mice, characterized by increased neutrophil infiltration. α_2 BAR overexpression did not affect the IL-1 β production by macrophage, while the migratory ability of neutrophils was significantly enhanced in α_2 BAR-overexpressing neutrophils.

Increasing evidence show that adrenergic receptors have a close relationship with immune system. All the three families of AR have already been reported to play a role in regulating innate immune responses and immune-related diseases (2, 20). For instance, β ARs are highly and widely expressed in immune cells. They regulate a number of functions, including lymphocytes homing and maturation (8, 21, 22). Previous studies have also shown a negative influence of norepinephrine on NK cell activity via β_2 ARs (23). In our study, we found for the first time that there was a significantly increased number of inflammatory cells in peritoneal cavity of α_2 BAR-Tg mice upon MSU treatment. IL-1 β is considered as a critical pro-inflammatory cytokine in the gout, with a wide range of systemic and local effects. In humans, the production of IL-1 β by resident macrophages is stimulated by MSU crystal and plays as a crucial role in the pathogenesis of gout (14). Moreover, IL-1 β has the ability to induce neutrophilia and neutrophil migration (24). It has been reported that exposure of macrophages to lipopolysaccharide led to a release of catecholamines and there is an autocrine/paracrine self-regulatory mechanism in catecholamine production by

macrophages during inflammation (25). Blockade of α_2 AR or catecholamine-generating enzymes greatly suppressed LPS-induced inflammation (25). Catecholamines has been shown to be able to promote NF- κ B signaling in macrophages via activating α_2 AR, leading to an amplification of the acute inflammatory response (26). However, we did not observe an increased IL-1 β production and caspase-1 activity in the α_2 BAR-overexpressing macrophages in our study. These data demonstrated that increased cytokines production induced by catecholamines may be independent of α_2 B-AR stimulation.

As an early event in immune response against invading pathogens, accumulation of neutrophils was also an early and critical step in sterile inflammation, such as gout and ischemia/reperfusion (27, 28). Inflammatory stimuli induce neutrophil mobilization from bone marrow, resulting in neutrophilia and neutrophil infiltration into the affected local area (29). In consistency with this, the number of neutrophil is significantly increased in the patients with acute gout. Both vagal parasympathetic and sympathetic signals have been shown to regulate inflammation through activating cholinergic receptors on macrophage and neutrophils (3, 30–32). It has been demonstrated that norepinephrine can induce immediate neutrophil mobilization through acting on α -AR (33), and leukocyte-expressing β_2 -AR has been found to be essential for survival after acute myocardial injury (34). Propranolol, a β_1 -AR/ β_2 -AR inhibitor, is able to reduce the numbers of circulating neutrophils, suppress neutrophil infiltration into colonic tissues, and attenuate the colonic tissue damage in IBD (35). Here, the increase of the inflammatory cell number in MSU-treated α_2 BAR-Tg mice was identified to a result of enhanced migratory ability of neutrophils as the absolute number of macrophage did not change. Furthermore, the number of neutrophils in bone marrow was similar between treatment naive α_2 BAR-Tg and WT mice, excluding the possibility that α_2 BAR may regulate neutrophil differentiation. The regulation of neutrophil function by SNS may vary in different diseases. Our findings indicate that α_2 BAR overexpression might play a critical role in the development of gout through promoting neutrophil recruitment into the inflammatory sites.

The migration process of neutrophil includes the following steps. The initial step of neutrophils is movement from the central stream to the periphery of a vessel, which allows the cell surface molecular interaction between neutrophil and vessel endothelial cell and then neutrophil rolling on the endothelial cells. After that, a chemoattractant gradient produced by local inflammation elicits the transmigration process of neutrophils (27). In our study, no difference in IL-1 β production was observed between Wt and α_2 BAR-Tg mice. In addition, mixed Wt and α_2 BAR-Tg neutrophils displayed different migratory ability in the same environment, regardless in Wt or α_2 BAR-Tg recipients. Furthermore, Wt and α_2 BAR-Tg neutrophils had an enhanced migration toward MIP2, while the CXCR2 receptor expression was similar to Wt neutrophils. These data suggest that the enhanced migratory ability in α_2 BAR-overexpressing neutrophils is independent of chemokine and chemokine receptors. Further investigations are required to understand the exact mechanisms by which α_2 BAR signals regulate the mobility of neutrophils.

Taken together, we demonstrated that α_2B AR is involved in the progress of MSU-induced inflammation and α_2B AR might be a promising therapeutic target for gout.

DATA AVAILABILITY

All datasets generated for this study are included in the manuscript and/or the supplementary files.

AUTHOR CONTRIBUTIONS

LD, XR, and JZ conceived the project, designed and carried out some experiments, analyzed all data, and wrote the paper. JC were responsible for design and performance of experiments, and contributed to analyzing data and writing the paper. YW, MR, and YT helped in performing all the experiments, analyzing all data, generating figures of the data. All the authors read,

critically revised, and agreed to be accountable for the content of manuscript.
