Zusammenfassung

Regulatorische Prozesse werden durch posttranslationale Proteinmodifikation eingeleitet, die seine Aktivität, seine Stabilität, seine Lokalisation innerhalb der Zelle oder seine Interaktion mit anderen Proteinen verändern. Neben vielen anderen solcher Prozesse stellen die Dekodierung des SUMOylierungssignals oder die Erkennung von lipidgebundenem Atg8 Ausgangspunkte für effektive Verarbeitungsrouten dar, die durch SUMO-Interaktionsmotive (SIMs) und Atg8-Interaktionsmotive (AIMs) in Proteinsequenzen eingeleitet werden. Ihr geringer Informationsgehalt verhindert jedoch ihre Unterscheidung von willkürlich auftretenden Sequenzen. Diese Dissertation handelt von einem Detektionsansatz mit bioinformatischen Methoden für bisher unbekannte SIMs und AIMs.

Der erste Teil dieser Arbeit beschreibt die bioinformatische SIM-Detektionsmethodik. Diese ist für alle drei SIM-Typen gleich, jedoch sind die einzelnen Suchläufe auf SIMa-, SIMb- und SIMr-Charakteristiken zugeschnitten. Als Maß für die Konservierung wurde eine informationstheoretische Metrik gewählt und auf jeweils zwei unterschiedlich weit gefasste phylogenetische Verwandtschaftsbereiche angewendet. Eine Kombination bioinformatischer Methoden dient zur Abschätzung, ob ein Proteinbereich unstrukturiert, nicht-globulär oder globulär ist. Der vorgestellte bioinformatische Ansatz verwendet Eigenschaften zu Konservierung und strukturellem Kontext für eine Wertungsmethodik zur Funktionalität neuer, noch unbekannter SIM-Instanzen.

Experimente zeigen SUMO-Interaktion für Dbp10, Drs1, Rfc1, Rad18 und Tdp1 aus den bioinformatischen SIM-Detektionsdurchläufen. Dbp10 und Drs1 treten in der ribosomalen Biogenese im Nukleolus auf. Ein SIM ist in diesem biologischen Kontext noch nicht bekannt, obwohl SUMOylierung hier im Zusammenhang mit dem Übergang präribosomaler Partikel ins Nukleoplasma auftritt. Tdp1, Rfc1 und Rad18 treten im Zusammenhang mit DNS-Replikation und in der DNS-Schadensreparatur auf, in denen SUMOylierung als wichtiger Aktivitätsfaktor für andere Proteine bekannt ist. Für das Motiv in Rfc1 konnte im Rahmen dieser Arbeit eine Verantwortlichkeit für SUMO-Bindung in Mutationsstudien gezeigt werden. Es verursacht auch einen beobachtbaren Wachstumsphänotyp unter chemisch-induziertem DNS-Schadensstress. Das Motiv in Rad18 wurde in der Zwischenzeit auch von Parker und Ulrich identifiziert.

Im zweiten Teil dieser Arbeit wird eine Anwendung analoger Methoden für einen bioinformatischen AIM-Detektionsansatz beschrieben. Die Konservierungscharaktika etablierter AIM-Instanzen sind ähnlich zu denen von etablierten SIMs, wobei der strukturelle Kontext für AIMs mit bioinformatischen Methoden schwerer abzubilden ist.

Abstract

Regulatory processes are initiated by posttranslational modifications of proteins which alter their activity, stability, localization or their interaction with other proteins. Among many other processes, decoding the SUMOylation signal or the recognition of lipidated Atg8 represent starting points to effective downstream signalling pathways, initiated by SUMO interacting motifs (SIMs) and Atg8 interacting motifs (AIMs) in protein sequences. The low information contents of SIMs and AIMs prevent their detection from spurious sequences. This thesis is about a detection approach for so far unknown SIMs and AIMs with bioinformatical methods.

The first part of this thesis describes the bioinformatical SIM detection method. The overall method is common for all SIM types, whereas the single SIM detection screens apply to the characteristics for SIMa, SIMb and SIMr. Two sets of phylogenetic distances from budding yeast in combination with information theoretical approaches and sliding averages serve as a conservation measure. A combination of bioinformatical tools is used for an estimation whether a protein segment is unstructured, non-globular or globular. The bioinformatical approach in this thesis uses these conservation and structural features for the evolution of a functionality scoring measure for unknown SIM instances.

Experimental interaction studies show so far unknown SUMO interaction for Dbp10, Drs1, Rfc1, Rad18 and Tdp1 from the bioinformatical SIM detection screens. Dbp10 and Drs1 are involved in ribosomal biogenesis in the nucleolus. A SIM in this biological context has not yet been reported, whereas SUMOylation is involved in the release of pre-ribosomal particles into the nucleoplasm. Tdp1, Rfc1 and Rad18 are involved in DNA replication and damage repair, where SUMOylation is a crucial activity factor for other proteins. The motif in Rfc1 identified from the bioinformatical detection screen is shown responsible for SUMO interaction in mutation studies. This motif also causes observable growth phenotype under chemically induced DNA damage stress. The motif in Rad18 was meanwhile identified by Parker and Ulrich.

The second part of this study describes the application of analogous methods for a bioinformatical AIM detection approach. The conservation characteristics of established AIM are found similar to those for SIMs, whereas the structural context is harder to be represented with bioinformatical methods.

1. Introduction

Cells constantly have to overcome diverse situations that endanger cellular homeostasis: Starvation, damage to cell compartments, or just any disturbance in the sensitive balance of protein levels have to be detected and responded to by the cell.

The ubiquitin proteasome system (UPS) and ubiquitin-like (Ubl) protein conjugation pathways are integral to regulated proteolysis in the cell, but they also have essential multiple nondegradative biological roles. The UPS regulates location and activity of cellular proteins. Their function and malfunction are important factors in various human diseases such as cancer or neurodegenerative disorders [Bedford et al., 2011, review]. Breakdown of bulk proteins, carbohydrates and lipids constantly replenishes the cell's supply for carbon and nitrogen under starvation conditions. The detection of nonfunctional substrates and subsequent increase in repair mechanisms may be sufficient for the adaptation to a stress situation. Several repair pathways exist. But depending on the kind and severity of damage to the cell more drastic measures like apoptosis or senescence can be triggered to protect the tissue or the whole organism.

1.1. Posttranslational protein modification

Posttranslational modifications of proteins (PTMs) drive a variety of cellular processes in eukaryotes like regulation of cell growth, cell division, or adaptive and developmental processes. Protein modifications are covalent attachments which alter its properties. Most modifications make major structural contributions to their target proteins, as it is the case for phosphorylation, acetylation or methylation [Sartorelli et al., 1999, Ubersax and Ferrell, 2007, Plevoda and Sherman, 2007, Webster et al., 2014]. These modifications affect the activity, stability, localization or the interaction of proteins with other proteins. There are also other types of PTMs such as modification with ubiquitin-like proteins (Ubls) such as ubiquitin (Ub), the small ubiquitin-like modifier (SUMO) or the neural precursor cell-expressed, developmentally downregulated gene 8 (NEDD8). Modifications by Ubls introduce a new interaction site for proteins. Ubls share a three-dimensional structure that resembles ubiquitin in its characteristic tightly

1. Introduction

packed globular $\beta\beta\alpha\beta\beta$ -fold, also termed as “ β -grasp”, with β -sheets wrapped around an α -helix, whereas both primary sequence and charge surface distributions are highly diverse [Hochstrasser, 2000, Burroughs et al., 2007]. The respective Ubl structures are virtually superimposable (figure 1.1) [Bayer et al., 1998]. The evolutionary relationship of different Ubls suggest functional similarities, as all Ubls described so far are conjugated via similar conjugation machineries. These machineries employ E1, E2 and E3 enzymes on their way onto their respective target.

Figure 1.1. The ubiquitin fold as a structural element for ubiquitin-like modifiers. The β -grasp fold of ubiquitin (a) is a common structural core element for Ubls such as Atg8 [1UBI], Smt3 [2KQ7] and NEDD8 [2KO3]. Pictures were taken from the Protein Data Bank with the assigned identifiers. All structures were directly processed on the PDB web page using the “Jmol” application and the “screen shot” application. The structures were orientated in a similar conformation with the α -helix (bright purple) of the characteristic ubiquitin-like fold in front of the β -strands (yellow).

1.2. The ubiquitin conjugation machinery

Ubiquitin is a 76-residue protein, highly conserved within eukaryotes and found in all tissues of eukaryotic organisms, only with a sequence difference of three amino acids between plants, yeast and mammals [Hershko and Ciechanover, 1998]. It shares an almost identical conjugation process with its homologs in other species [Kerscher et al., 2006]. Ubiquitin is first expressed in an inactive form and needs processing at its carboxy terminus to expose a double glycine motif. After maturation of its C-terminus, ubiquitin is activated by an activating enzyme (E1) which catalyzes the formation of a high-energy thioester bond between its cysteine group and the carboxy terminus of ubiquitin [Haas et al., 1982]. The E1 acts as a catalyst and passes the modifier via transthioylation to the active cysteine side chain of a conjugating enzyme (E2) [Hershko et al., 1983, Hershko and Ciechanover, 1998]. Together with a substrate-specific E3 enzyme, the E2 catalyses ubiquitin transfer onto the target protein. The complexity of this posttranslational modification through ubiquitin is even increased by the fact that ubiquitin can form distinct polyubiquitin chains via seven lysine residues (K6, K11, K27, K29, K33, K48, K63)

1. Introduction

or the N-terminus [Yeh, 2009]. This allows fine control of numerous cellular pathways: K48-polyubiquitinated proteins are generally degraded by the 26S proteasome, while K63-polyubiquitinated proteins can target membrane proteins to the lysosomal degradation pathway. Whereas the chain topology is determined by the E2 enzyme, substrate specificity comes with the E3 ligases [Yeh, 2009]. In this final step, the E3 ligase promotes the transfer of ubiquitin onto a lysine of its substrate. There are three classes of ubiquitin E3 ligases with regard to sequence and mechanism: E3 enzymes either contain a HECT-type (homologous to E6AP carboxyl terminus), a RING-type (really interesting new gene) or U-box domain [Barlow et al., 1994, Huijbregtse, 1995, Borden et al., 1995, Hatakeyama et al., 2001, Jiang et al., 2001, Pringa et al., 2001]. The conserved HECT domain comprises ~ 350 amino acids with a conserved active site cysteine and is located at the E3 carboxy terminus. RING domains do not carry a covalently bound ubiquitin but rather serve as a scaffold to bring E2 and substrate in close proximity for transthiolation. A U-box domain forms a similar E2 binding surface as the RING domain. It lacks zinc ions, but is able to form stabilizing hydrogen bonds and salt bridges. The UPS pathway is initiated by the covalent attachment of ubiquitin to a target protein's amino group via the conjugation pathway [Pickart, 2001, Pickart and Eddins, 2004]. Ubiquitin is recognized by a number of pre-folded ubiquitin-binding domains (UBD) for substrate recognition. They are classified as UBA (ubiquitin-associated motif), UIM (ubiquitin interacting motif), UMI (UIM- and MIU-related UBD), DUIM (double-sided UIM), MIU (motif interacting with ubiquitin, or reversely orientated UIM), CUE (coupling of ubiquitin conjugation to endoplasmic reticulum degradation), UEV (ubiquitin E2 variant), UBZ (ubiquitin-binding zinc finger) and UBM [Wilkinson et al., 2001, Mueller and Feigon, 2002, Hofmann and Falquet, 2001, Oldham et al., 2002, Pornillos et al., 2002, Swanson et al., 2003, Donaldson et al., 2003, Kang et al., 2003, Prag et al., 2003, Shih et al., 2003, Sundquist et al., 2004, Bienko et al., 2005, Penengo et al., 2006, Hirano et al., 2006, Pinato et al., 2011, Burschowsky et al., 2011]. They all have in common that they are composed of one or more α -helices binding to a hydrophobic patch on ubiquitin around Ile44. The general process of how ubiquitin and other Ubls get conjugated onto a substrate is well understood, however, the characteristics of their respective recognition sites in specific substrates and therefore the target specificity of a given modifier are still not known.

1.3. The Small Ubiquitin-like Modifier in *Saccharomyces cerevisiae* (SUMO)

SUMO proteins are expressed in all eukaryotes, but while *Saccharomyces cerevisiae*, *Caenorhabditis elegans* and *Drosophila melanogaster* have one SUMO gene, organisms such as plants and vertebrates have several genes. It encodes a 101 amino acid polypeptide with 18% sequence identity to ubiquitin. The human genome encodes four SUMOs with SUMO1-3 expressed ubiquitously and SUMO4 mainly expressed in kidney, lymph node and spleen [Guo et al., 2004]. SUMO was shown to be a reversible modifier of proteins. Its attachment, called SUMOylation, can alter the protein localization by altering protein interactions. SUMOylation is a modification with important functions ranging from DNA damage control to regulation of mitochondrial dynamics [Livnat-Levanon and Glickman, 2011]. The *Saccharomyces cerevisiae* orthologue SMT3 of the mammalian SUMO was discovered in a genetic suppressor screen for the centromeric protein Mif2 [Meluh and Koshland, 1995, Mannen et al., 1996]. Additionally, SUMO was found to be covalently attached to the RanGTPase activating protein RanGAP1 and as binding partner for human Rad51 and Rad52 [Shen et al., 1996, Matunis et al., 1996, Mahajan et al., 1997].

1.3.1. SUMO conjugation

In yeast, the activation of SUMO is carried out by the heterodimeric protein complex Aos1-Uba2, after maturation of the otherwise unfunctional SUMO to expose the C-terminal GG motif [Johnson et al., 1997, Desterro et al., 1999, Gong et al., 1999, Okuma et al., 1999, Johnson, 2004]. Aos1 (activation of Smt3) resembles the N-terminus of Uba1, the ubiquitin activating enzyme (E1), whereas Uba2 shows structural homology to the C-terminus of Uba1. This close structure/function relationship shows how strongly related the conjugation machineries of ubiquitin and SUMO are. Similar to ubiquitin, the activation of SUMO is ATP-dependent and leads to a SUMO-adenylate conjugate which is an intermediate species in the thioester formation between SUMO and the active site cysteine in Uba2 within the Aos1-Uba2 complex [Dohmen et al., 1995, Johnson et al., 1997]. Upon activation, SUMO is transferred from the Aos1-Uba2 complex to a cysteine of the essential E2 conjugating enzyme Ubc9 [Johnson et al., 1997, Desterro et al., 1997, Schwarz et al., 1998]. In this step, Ubc9 binds both SUMO and the Aos1-Uba2 enzyme complex which places the two active cysteine residues into close proximity for SUMO transfer [Desterro et al., 1999, Gong et al., 1999, Lee et al., 1998, Saitoh et al., 1998, Wang et al., 2007]. Structural data suggest that the multi-protein binding surface

1. Introduction

of Ubc9 establishes contact to the Ψ KxE motif of a given substrate (with Ψ a large hydrophobic amino acid, K the SUMO target lysine residue, x a wild-card amino acid and E a glutamic acid residue) [Sampson et al., 2001, Bernier-Villamor et al., 2002].

1.3.2. SUMO ligases

Like ubiquitin, SUMO also engages E3 ligases to assist in the final step of conjugation and to promote the transfer of SUMO to a lysine residue in the substrate. The number of SUMO E3 enzymes is smaller than the number of E3s of ubiquitin. As a characteristic, the largest group of SUMO E3 ligases bears a SP-RING motif, which resembles the RING domain in ubiquitin E3 ligases [Hochstrasser, 2001]. SP-RING E3 ligases bind both their substrates and Ubc9 directly, and then position SUMO via a noncovalent SUMO interaction motif for a favorable SUMO-to-target orientation. The SP-RING ligases can be subdivided into different classes: The PIAS (protein inhibitor of activated STAT) protein family comprises a group of proteins which were initially described as negative regulators of cytokine signaling that inhibits STAT-transcription factors [Chung et al., 1997, Liu et al., 1998]. The PIAS-family with its yeast members Siz1 and Siz2 (SAP and miz-finger domain protein) and mammalian PIAS1, PIAS3 with splice variants PIASx α , PIASx β and PIASy [Johnson and Gupta, 2001, Kahyo et al., 2001, Kotaja et al., 2002, Nakagawa and Yokosawa, 2002, Nishida and Yasuda, 2002, Sachdev et al., 2001, Schmidt and Müller, 2002]. Other SP-RING E3 ligases are Mms21 (methyl methanesulfonate sensitivity protein 21) and Zip3 [Roeder and Agarwal, 2000, Takahashi et al., 2001, Zhao and Blobel, 2005, Reindle et al., 2006]. Mms21 is part of an octameric Smc5-Smc6 complex essential for vegetative growth and DNA repair [Zhao and Blobel, 2005, Andrews et al., 2005, Potts and Yu, 2005]. Zip3 is part of the synapse-initiation complex [Cheng et al., 2006]. Human RanBP2 (Ran binding protein 2) is another SUMO E3 ligase, but without an SP-RING [Mahajan et al., 1997, Mahajan et al., 1998]. Its catalytic domain is located in a natively unfolded protein region assuming that the domain structure is established just upon binding to Ubc9 [Pichler et al., 2004, Reverter and Lima, 2005]. Further SUMO E3 ligases are the human Polycomb group member Pc2 (polycomb 2) [Kagey et al., 2003, Kagey et al., 2005], HDAC4 (Histone deacetylase 4) [Kirsh et al., 2002, David et al., 2002] and TOPORS (DNA topoisomerase I binding protein) [Weger et al., 2003, Weger et al., 2005].

A SUMO moiety attached to a target protein alters the protein shape and its surface charge distribution. The final effects of SUMOylation on a substrate may be numerous. SUMOylation may act as an ON-switch for interaction: only SUMOylated RanGAP1 interacts with RanBP2 and SUMOylated PCNA recruits yeast DNA helicase Srs2 to

1. Introduction

replication forks [Matunis et al., 1996, Mahajan et al., 1997, Papouli et al., 2005, Pfander et al., 2005]. SUMOylation can also be an OFF-switch for interaction as it is the case for the transcription repressor ZNF76: Its SUMO-acceptor site interferes with its binding site for the TATA-binding protein and therefore, only one interaction is possible at a time [Zheng and Yang, 2004].

1.3.3. The SUMO interacting motif

SUMOylation proceeds via covalent modification of the target protein, whereas decoding of the SUMO signal depends on noncovalent interactions. Hecker *et al.* suggested a β -sheet of the SUMO-fold as SUMO/SIM interaction site [Hecker et al., 2006]. Minty and co-workers were the first to suggest a specific consensus pattern for SUMO interacting motifs (SIM) [Minty et al., 2000]. Minty *et al.* derived an 11-amino-acid stretch from sequence comparisons of the isolated proteins as an assumed SUMO-1 interaction site:

An “Ser-X-Ser” motif is preceded by hydrophobic residues and followed by acidic residues at its carboxy terminus. NMR studies by Song *et al.* drew the attention away from the serine residues in Minty’s “Ser-X-Ser” motif as core element in SUMO-1 binding. They evolved a consensus pattern focused on a hydrophobic core [Song et al., 2004]:

This motif has been found in several proteins like the SUMO ligases PIASX and RanBP2 and acts as binding site [Song et al., 2004, Song et al., 2005]. Solution structures of a SIM peptide in M-IR2 binding to SUMO1 (figure 1.2(a)) and a SIM peptide in MCAF1 binding to SUMO3 (figure 1.2(b)) indicate the same SUMO surface for SUMO/SIM interaction [Namanja et al., 2012, Sekiyama et al., 2008]. The same surface of the β -grasp fold is employed for binding in both structures.

Their structures and the works of Hannich *et al.* showed new SUMO interacting proteins like yeast Fir1, Nis1, Ris1 and Sap1 for a refined SIM consensus [Hannich et al., 2005]:

1. Introduction

Figure 1.2. NMR solution structures show a functional binding site for noncovalent SUMO/SIM interaction. SIMs bind to a surface between α -helix (purple) and β -strand of the ubiquitin-like fold and extends to the β -sheet (both yellow). Depicted here are the following published structures: (a) A structural NMR study of SUMO1 in complex of a peptide comprising the SUMO1-specific M-IR2 SUMO interacting motif (SIM)[2LAS] [Namanja et al., 2012]. (b) A solution structure derived from NMR spectroscopy shows that the MCAF1 SIM employs the same surface of the SUMO fold [2RPQ] [Sekiyama et al., 2008]. The figures show the solution structures placed in a similar orientation to the observer to indicate common structural and binding characteristics. The SIM approaches the ubiquitin-like fold from a bottom right direction in a superimposable way. White arrows in the figures are pointed at the SIM. The arrow in figure (b) is drawn shorter not to cover the protein fold. All structures were taken from the Protein Database (PDB) web page using the “Jmol” application on that page. The images were taken by screen-shot from that application.

Additionally, it was reported that binding to SUMO can be performed in both sequence orientations, giving more variability in protein topology [Reverter and Lima, 2005, Song et al., 2005, Uzunova et al., 2007]. In 2007, Uzunova *et al.* performed yeast two-hybrid experiments with Smt3 as bait, in which they confirmed Siz1, Nis1, Fir1, Slx5 and Ris1 as SUMO interacting proteins (SIPs). They established a classification of SIMs into three types, ‘SIMa’, ‘SIMb’ and ‘SIMr’ [Uzunova et al., 2007]: A SIMa consensus sequence is composed of four hydrophobic amino acids followed by several acidic residues. The SIMr consensus sequence is like the one for SIMa, but with a reverse orientation of the sequence. The SIMb consensus sequence is composed of a shorter stretch of less variant hydrophobic residues. An acidic stretch at its carboxy terminus seems to be conserved, but less than for the other SIM consensus sequences. Experimental data helped to make a list of established SIMs (table 1.1). All motifs show close similarity to one of the three consensus types. Grouping these motifs in one of the three SIM types allows their information theoretical representation [Schneider et al., 1986, Schneider and Stephens, 1990]. These representations are based on information theory and display the residue variation in alignments of protein or nucleic sequences. A web-based application is provided by SeqLogo [Crooks et al., 2004]. The information theoretical SeqLogo approach can be applied to the list of established SIMs as another SIM representation aside from classical consensus pattern representations to each of the three SIM types SIMa, SIMb and SIMr (figure 1.2).

1.3.4. SUMO-targeted ubiquitin ligases

Not only single SUMO moieties serve as targeting signals. Protein modification by SUMO chains represents recognition signals to a novel class of SUMO-targeted ubiquitin ligases (STUbLs) or ubiquitin ligases for SUMOylated proteins (ULS, E3-S). One function of this class of proteases is the STUbL-mediated ubiquitination of SUMOylated proteins as a signal for proteasomal degradation. For this purpose, STUbLs show two

1. Introduction

characteristics: a RING domain for interaction with an E2 ubiquitin-conjugating enzyme and multiple SUMO interacting motifs for SUMO binding [Uzunova et al., 2007, Tatham et al., 2008].

The human Rnf4 protein (RING finger protein 4) is so far probably the best described STUbL [Prudden et al., 2007, Sun et al., 2007, Lallemand-Breitenbach et al., 2008, Tatham et al., 2008, Weisshaar et al., 2008]. Its architecture with at least three SUMO interacting motifs shows clear preference for binding of SUMO chains [Tatham et al., 2008]. A RING domain allows formation of a Rnf4 homodimer and binding of a single ubiquitin-charged E2 [Liew et al., 2010, Plechanovova et al., 2011, Plechanovova et al., 2012]. Several RNF4 substrates were found: Its ubiquitin ligase activity plays a crucial role in the ubiquitination of SUMOylated PML (promyelocytic leukemia protein) and in the disruption of PML nuclear bodies (PML–NB) in cells treated with arsenic trioxide (ATO) [Lallemand-Breitenbach et al., 2008, Tatham et al., 2008, Weisshaar et al., 2008]. ATO induces PML oligomerization and an increased affinity for Ubc9 [Zhang et al., 2010]. Poly-ubiquitination directs SUMOylated PML to the 26S proteasome for degradation [Tatham et al., 2008, Lallemand-Breitenbach et al., 2008].

In yeast, Slx5 is part of the DNA binding heterodimer Slx5–Slx8, also known as Uls2 [Wang et al., 2006, Yang et al., 2006, Ii et al., 2007a, Xie et al., 2007b, Uzunova et al., 2007]. This complex was also identified as STUbL from yeast two-hybrid data [Hannich et al., 2005, Uzunova et al., 2007, Xie et al., 2007b]. Both subunits contain a RING finger domain which was shown essential for dimer formation [Tatsuya Ii and Brill, 2007]. The Slx5 RING finger allows binding to Slx8, the Slx8 RING finger is the active ubiquitin ligase. Slx5 comprises several SIMs and is responsible for binding of SUMOylated proteins [Tatsuya Ii and Brill, 2007]. But Slx5–Slx8 can target substrates in a SUMO-independent manner [Xie et al., 2010]. The heterodimer is a ubiquitin ligase that links SUMOylation to recombinational DNA repair [Ii et al., 2007b, Xie et al., 2007b]. Slx5 and Slx8 are required for the viability of yeast cells lacking the Sgs1 DNA helicase [Kaliraman et al., 2001, Mullen et al., 2001]. *slx5*Δ and *slx8*Δ null mutants show slow growth, sensitivity to hydroxy urea (HU) and increased rates of gross chromosomal rearrangements and mitotic recombination [Mullen et al., 2000, Ii et al., 2007a, Xie et al., 2007b]. Slx5 and Slx8 mutations are synthetically lethal when combined with mutations in the SUMO pathway [Wang et al., 2006]. SUMO interacting activity of Uls1 was found in a yeast two-hybrid screen [Hannich et al., 2005, Uzunova et al., 2007]. Uls1 is a ubiquitin ligase for SUMO conjugates. The Uls1 protein architecture comprises four SIMs in the amino terminal half, a Swi2/Snf2-like translocase motif and a RING domain in the carboxy terminal half [Dresser et al., 1997, Zhang and Buchman, 1997, Hannich et al., 2005, Uzunova

1. Introduction

et al., 2007, Cal-Bakowska et al., 2011]. The combination of SIMs and RING domain suggests putative STUbL activity. Uls1 also binds to SUMO and SUMOylated proteins and shows interaction with Ubc4 ubiquitin ligase E2 in pulldown assays [Uzunova et al., 2007, Tan et al., 2013]. Uls1 mutant strains accumulate high molecular weight SUMO conjugates (HMW) and display synthetic growth effects [Uzunova et al., 2007]. These effects are increased in *uls1* Δ *slx5* Δ or *uls1* Δ *slx8* Δ double mutants [Pan et al., 2006, Uzunova et al., 2007]. Nevertheless, ubiquitin ligase activity of Uls1 has not yet been reported.

1.3.5. DeSUMOylation

For cell cycle progression and regulation of many processes, it is essential for a cell to be competent to remove the covalently attached SUMO from a given substrate at a given point of time. The de-modification is carried out by SUMO-specific proteases. This class of enzymes has two distinct functions: they C-terminally cleave the newly synthesized SUMO precursors to expose the di-glycine motif prior to conjugation, acting as so-called peptidases. They may also reverse SUMOylation by dissolving the SUMO isopeptide bond to its substrate and are therefore called isopeptidases. Both peptidases and isopeptidases are subclasses of hydrolases cleaving amide bonds by hydrolysis. Among these deSUMOylating enzymes are yeast Ulp1 and Ulp2 (Ubl specific protease) with a characteristic conserved approximate 200 amino acid C-terminal catalytic domain which is essential for the deSUMOylation activity [Li and Hochstrasser, 1999, Schwienhorst et al., 2000, Mossessova and Lima, 2000]. They have six human homologs SENP1–3, SENP5–7 (senptrin-specific proteases) [Mukhopadhyay and Dasso, 2007]. Ulp1 possesses cysteinyl proteinase activity. Additionally, Ulp1 deconjugates single SUMO moieties or SUMO chains from the ϵ -amino residue of the substrate. These functions are required for cell cycle progression in *Saccharomyces cerevisiae* [Li and Hochstrasser, 1999]. Ulp1 is SUMO specific. It lacks any sequence similarity to known ubiquitin deconjugating enzymes and is unable to deconjugate ubiquitin-targeted substrates. Ulp2, a second deSUMOylating proteinase, was found together with SUMO in the same screen for suppressors of a Mif2 mutation [Li and Hochstrasser, 2000]. Ulp2 was also found to have deSUMOylating activity and is located in the nucleus. It is not involved in SUMO maturation, but is required for chromosomal stability and for recovery from cell cycle checkpoint arrest [Li and Hochstrasser, 2000, Strunnikov et al., 2001, Bachant et al., 2002, Bylebyl et al., 2003, Felberbaum and Hochstrasser, 2008, Lee et al., 2011].

1.4. Autophagy

Autophagy plays a crucial role in the maintenance of a positive energy balance upon starvation stress [Kroemer et al., 2010, Ravikumar et al., 2010]. Dysfunctions in autophagic pathways are therefore associated with several diseases [Levine and Kroemer, 2008, Levine et al., 2011, Mizushima et al., 2008, Mizushima and Komatsu, 2011]. Autophagic pathways selectively remove aggregated proteins, surplus, damaged organelles and bacterial cells [Mizushima et al., 2008, Kirkin et al., 2009b, Noda and Yoshimori, 2009]. A crucial step is the formation of internal membranes in the cytoplasm which in turn form unique organelles, called autophagosomes [Baba et al., 1994, Kirisako et al., 1999, Suzuki et al., 2001, Mizushima and Komatsu, 2011]. Autophagosomes have been suggested to emerge from ER membranes [Hayashi-Nishino et al., 2009, Hayashi-Nishino et al., 2010]. More than 30 autophagy-related genes (Atgs) are involved in autophagy [Suzuki et al., 2007, Mizushima et al., 2011]. Most Atgs are involved in the following processes:

(i) The Atg1 kinase complex and its regulators [Matsuura et al., 1997, Cheong et al., 2008, Yeh et al., 2010, Kijanska and Peter, 2013]. Complex activity is enhanced upon starvation and plays a crucial role in autophagosome formation [Kamada et al., 2000]. It is composed of Atg1, Atg11, Atg13, Atg17, Atg20, Atg24, Atg29 and Atg31. Atg1 serves as a Ser/Thr kinase. It is directly connected to the Tor signaling pathway. Starvation induces dephosphorylation of Atg13. Atg13 now has a larger binding affinity to Atg1 increasing Atg1 kinase complex activity [Kamada et al., 2000, Funakoshi et al., 1997, Scott et al., 2000, Cheong et al., 2008].

(ii) A ternary Atg17–Atg29–Atg31 complex associates with Atg1. This also enhances Atg1 kinase complex activity. In a second step, the Atg17–Atg29–Atg31 complex recruits Atg proteins to the preautophagosomal structure (PAS) [Suzuki et al., 2001, Kawamata et al., 2008, Cheong et al., 2008]. Whereas Atg11 and Atg17 serve as a scaffold for PAS under nutrient-rich conditions, the Atg1–Atg13 complex associates with the Atg17–Atg29–Atg31 complex upon starvation [Shintani et al., 2002, Kawamata et al., 2008].

(iii) The phosphatidylinositol 3-kinase complex (PtdIns3) in *Saccharomyces cerevisiae* is Vps34 [Schu et al., 1993]. It forms a ternary Vps34–Atg6–Atg14 complex which is targeted to the PAS, whereas the Vps34–Atg11–Vps38 complex is required for vacuole protein sorting by the endosome [Kihara et al., 2001, Obara et al., 2006, Dove et al., 2004]. Atg14 recruits PtdIns3 binding proteins to the PAS, including Atg18. Atg18 in turn forms a Atg18–Atg2 complex which is responsible for Atg9 cycling between peripheral structures and the PAS [Noda et al., 2000, Reggiori et al., 2004, Suzuki et al., 2007].

1. Introduction

(iv) Immunoelectron microscopy data suggest a central role for Atg8 in the autophagic pathway [Kirisako et al., 1999, Kirisako et al., 2000]. Atg8 is lipidated after ubiquitin-like conjugation to phosphatidylethanolamine into the autophagic membrane, a key process in autophagosome formation [Tanida et al., 2003, Kabeya et al., 2000, Kabeya et al., 2004].

1.4.1. The Atg8 conjugation cascade

Atg8 conjugation to phosphatidylethanolamine is dependent on two ubiquitin-like conjugation systems: Atg8 is attached to the lipid phosphatidylethanolamine (PE) via a ubiquitin-like conjugation mechanism. After proteolytic maturation cleavage by the protease Atg4, modified Atg8 is activated by the E1 enzyme Atg7 [Kirisako et al., 2000, Kim et al., 2001a]. Subsequently, activated Atg8 is transferred to the E2 enzyme Atg3 and finally conjugated to the amino group of the target lipid PE. This last step is catalyzed by an unusual E3 enzyme, which is a complex of Atg16 and Atg5, covalently modified by another ubiquitin-like modifier called Atg12 [Hanada et al., 2009]. Atg12 is activated by the E1 enzyme Atg7 and its specific E2 enzyme Atg10 for its covalent conjugation to Atg5. The Atg12-modified Atg5 associates with Atg16, thus forming the E3 for the transfer of Atg8 onto lipid-PE [Hanada and Ohsumi, 2005, Hanada et al., 2007, Kuma et al., 2002].

1.4.2. The Atg8 family proteins share a common fold

Atg8 with its central role in the autophagic system is the most prominent member of the Atg. Whereas only one ATG8 gene is known in yeast, there are six Atg8 homologs in mammals: LC3A, LC3B, LC3C, GABARAP, GABARAPL1, GATE-16/GABARAPL2 [Mann and Hammarback, 1994, Wang et al., 1999, Sagiv et al., 2000, Xin et al., 2001, He et al., 2003]. Their expressed proteins are here referred to as the Atg8 family proteins. The three-dimensional structures of Atg8 family proteins show a C-terminal ubiquitin fold and an N-terminal helical extension (figure 1.3). [Paz et al., 2000, Stangler et al., 2002, Sugawara et al., 2004, Noda et al., 2008, Duszenko et al., 2011]. The N-terminal region consists of two α -helices and is a unique feature of Atg8 that distinguishes it from other Ubls. All Atg8 family proteins have exposed β -strands, which are responsible for their interaction upon intermolecular β -sheet expansion. They all have two hydrophobic pockets, termed W-site (E17, I32, K48, L50, F104) and L-site (Y49, V51, P52, L55, F60, V63) [Noda et al., 2008]. The interaction between autophagic receptors and Atg8 contributes to specific cargo selection, whereas the AIM anchors the cargo with its

1. Introduction

receptor to lipidated Atg8 [Ichimura et al., 2008, Kirkin et al., 2009a, Noda et al., 2008, Okamoto et al., 2009].

Figure 1.3. The solution structures of the Atg8 homologs show the characteristic β -grasp fold. The structures were taken from the Protein Database. Yeast Atg8 (a): 2KQ7 [Schwarten et al., 2010]. Mammalian LC3 (b): 1V49 [Kouno et al., 2005]. Mammalian GABARAP (c): 1KOT [Stangler et al., 2002]. All tertiary structures are placed in a similar orientation to display the common β -grasp fold with its β -strands (yellow) to the back and its characteristic α -helix (purple) to the front.

1.4.3. Substrate recognition and the Atg8 interacting motif

In autophagy, specific adaptor proteins link selective autophagy cargo to lipidated Atg8 family members and thus to the autophagy machinery. In yeast, such adaptors additionally bind Atg11 for both selective autophagy and the cytoplasm-to-vacuole targeting (CVT) pathway [Yorimitsu and Klionsky, 2005]. The CVT pathway is closely related to autophagy but serves as non-conventional targeting of Ams1 (α -mannosidase 1) and Ape1 (aminopeptidase 1) to the vacuole [Baba et al., 1997, Scott et al., 1997, Scott et al., 2001]. Atg19 and Atg34 mediate the incorporation of oligomerized structures of Ams1 and Ape1 in CVT vesicles [Watanabe et al., 2010]. Under both nutrient-rich and starvation conditions, Atg19 mediates the association of the CVT complex with the PAS via interaction with Atg8 and Atg11 [Hutchins and Klionsky, 2001, Shintani et al., 2002, Chang and Huang, 2007]. Under starvation conditions, Atg19 binding to Ams1 is no longer possible, which is then accomplished by the cargo receptor Atg34 [Watanabe et al., 2010, Suzuki et al., 2010]. The first Atg8 interacting motif (AIM) was described in the protein Atg19, which is the substrate recognition factor of the yeast CVT [Scott et al., 2001, Kim et al., 2001b]. The Atg19/Atg8 interaction could be attributed to a WEEL motif in Atg19. The Atg19 AIM adopts an extended β -conformation and an intermolecular parallel β -sheet with β 2 of Atg8 (figure 1.4(a)) [Watanabe et al., 2010]. A similar site was found in Atg34 as an WEEI motif [Watanabe et al., 2010]. Atg11 binds cargo-receptors in an AIM-independent manner, implying that Atg8 and Atg11 use distinct binding sites in cargo receptors Atg19 and Atg34 [Okamoto et al., 2009].

1. Introduction

Figure 1.4. Solution structures of AIM (LIR in mammals) binding to different Atg8 homologs show a common binding site. The AIM (LIR) binding to a Atg8 homolog is structurally comparable to SIM binding to SUMO. It involves the same structural element with respect to the β -grasp fold, as can be seen from published structural data: Shown here are solution structures representing the interaction between Atg8/Atg19 (a, PDB 2ZPN), LC3/p62 (b, PDB 2K6Q), LC3B/OPTN (c, PDB 2LUE) and GABARAP1/NBR1 (d, PDB 2L8J). The respective structures are aligned to each other with respect to the ubiquitin-like structural core in a similar orientation with the β -strands to the back (yellow) and the characteristic α -helix to the front. The AIM approaches that fold at a cleft between that helix and the β -strands from a bottom right direction.

The Atg8 interaction of Atg19 is enhanced by concomitant binding to Atg11. There are other proteins bearing AIM. Atg32 is an outer-membrane, mitochondria-anchored receptor protein and bears an AIM for direct Atg8 binding [Kanki and Klionsky, 2008, Kanki et al., 2009, Okamoto et al., 2009, Aoki et al., 2011]. In mammals, a similar function is ascribed to Nix (mammalian Nip3-like protein, also known as BNIP3-like, BNIP3L) [Novak et al., 2010, Schwarten et al., 2009]. The pexophagy receptor Atg36 is shown to bind to Atg8 and the peroxisome via Pex3 [Motley et al., 2012, Farre et al., 2013]. Motley *et al.* suggested eight putative AIMs in Atg36 from sequence similarities to other AIMs, however the functional AIM could not be detected so far. A FDDI motif is better conserved than the other AIM candidates and thus might be functionally most important [Motley et al., 2012].

Other autophagic receptors responsible for the recognition of specific cargo have been described in mammals, including p62 [Bjørkøy et al., 2005, Komatsu et al., 2007, Pankiv et al., 2007, Ichimura et al., 2008] and NBR1 in mammals [Kirkin et al., 2009a, Waters et al., 2009]. p62 interacts with ubiquitinated proteins via its C-terminal UBA domain and oligomerizes with other “loaded” p62 via its N-terminal PB1 domain [Wilson et al., 2003, Moscat et al., 2007, Seibenhener et al., 2007, Saio et al., 2009, Nakamura et al., 2010, Isogai et al., 2011]. Docking to nucleating autophagosomes is mediated by the LC3 interacting motif (LIR in mammals, AIM in yeast) [Pankiv et al., 2007, Ichimura et al., 2008]. NDP52 was found as a receptor for ubiquitin-coated *Salmonella enterica serovar Typhimurium* [von Muhlinen et al., 2010, Thurston et al., 2009]. It has a carboxy-terminal zinc finger for ubiquitin binding and an LC3 interacting motif, char-

1. Introduction

acteristics NDP52 shares with p62 and NRB1 [von Muhlinen et al., 2012]. Optineurin (OPTN) is an adaptor protein in the pathogen-induced autophagy pathway. OPTN has been shown to be an autophagy adaptor for ubiquitin-coated *Salmonella enterica* [Perrin et al., 2004, Wild et al., 2011]. It interacts with LC3/GABARAP via a LIR/AIM motif (figure 1.4(c)). Interestingly, Ser-170 within this LIR is phosphorylated by TBK1, making it more acidic and thus increasing its affinity for LC3/GABARAP [Kirkin et al., 2009a, Novak et al., 2010, Behrends et al., 2010]. A consensus pattern for AIM was evolved with experimental data (table 1.4, figure 1.5) [Alemu et al., 2012].

1.5. Comparison between Ubiquitin, SUMO and Atg8 interaction

The tightly packed globular $\beta\beta\alpha\beta\beta$ tertiary structure is a common characteristic for ubiquitin, SUMO and Atg8, despite their low degree of sequence similarity to each other [Vijay-Kumar et al., 1987, Bayer et al., 1998, Schwarten et al., 2010, Kumeta et al., 2010, Ganoth et al., 2013]. The differences in individual conjugation machineries are as follows: Whereas the basic principles of conjugation are the same with Ubls, the number of known representatives of each enzyme class E1, E2 and E3 varies. Ubiquitin employs numerous E2 enzymes and a large number of E3 ligases as a means of substrate specificity, SUMO has far less of each. Atg8 only involves one E1, E2 and E3 each. Substrate specificity comes from the cargo receptor. Ubiquitin, SUMO and Atg8 also differ in modifier recognition: Ubiquitin employs already pre-folded structural elements. Protein binding to SUMO and Atg8, on the contrary, proceed via small interaction motifs (SIM and AIM, respectively) forming β -strands upon Ubl binding (figures 1.2(a), 1.4(a)). These short binding motifs lie in structurally well solvent accessible, and therefore likely unstructured protein regions. These protein regions serve as a coupler between globular segments or lie close to sequence ending regions. In general, these sequence regions are not critical to function and show more sequence variation due to less evolutionary pressure. Functional short motifs of 3 to 10 amino acids in length in those protein segments show a distinct pattern of amino acid conservation. Multi-sequence alignment tools have difficulties in dealing with short conserved patches in otherwise more variant protein regions, as these tools are developed and trained on well-defined globular regions of more than 100 amino acids in length. A protein sequence database screen with a consensus motif pattern therefore gives a large number of potential motifs. An evaluation and distinction in true functional and incorrect occurrences due to the low information content of short linear motifs is a difficult computational problem.

1.6. Bioinformatics

Proteins usually fold natively into multiple sub-folding units, so called domains, rather than in one monolithic fold. These domains are able to act as intermolecular binding sites. A closer look into the three-dimensional structures and sequences of proteins shows: Hydrophobic amino acids are enriched within globular structures. Hydrophilic residues are found at sites of solvent contact — either on the outside of globular domains, or in unstructured linker regions.

The structure/function approach associates domains with particular functions such as

1. Introduction

enzymatic activity or ligand recognition. This approach describes protein evolution as a number of single events with effects on domains. Autonomously folding domains evolve separately, as sequence changes in domains do not disturb the overall protein integrity. The comparative sequence analysis approach on proteomes from distinct species allows to derive functional information from already characterized sequences. Sequence homology uses the derived information as an anchor towards a transfer to novel sequences. In terms of evolution, homologs can be divided into orthologs and paralogs. Orthologous genes evolved from a single gene in the last common ancestor, paralogs arose from gene duplication [Ohno, 1970, Fitch, 1970]. Because inheritance represents the evolutionary relationship between orthologous genes, inherited functionality is therefore highly similar between those genes [Koonin, 2005, Schreiber and Sonnhammer, 2013].

Globular domains usually comprise more than 30 amino acids. Their information content is larger than for smaller protein segments. This allows distinct classification and storage in databases like Pfam [Bateman et al., 2004, Finn et al., 2014]. Protein regions shorter than about 20 amino acids show no natively folding substructure, as the internal stabilization is not sufficient. These regions are referred to as “motifs” or short linear motifs. Upon binding to a suitable binding partner, some of these motifs can adopt a tertiary structure. It often remains unclear, whether the folding or the binding step preceded. By contrast, short sequence modules such as motifs functioning independently from tertiary structure have been so far neglected.

The *Saccharomyces cerevisiae* genome has been completely sequenced [Goffeau et al., 1996]. The *Saccharomyces* Genome database (SGD)¹ stores more than 5,000 verified open reading frames (ORFs) as a center for different sequence data mining approaches [SGD, 2013]. That access to protein structures as well as sequence data sharpens the view on protein biology, as it allows both structure and sequence comparisons in combination with results from functional studies.

1.6.1. Short linear motifs

Traditionally, protein-protein interaction was believed to be restricted to large globular protein structures. Interaction between these distinct three-dimensional folded segments was thought to be the only way to fulfill a vast number of biological functions. In the last decades, scientific interest gets more and more focussed on highly flexible protein regions, especially highly conserved, but short sequence stretches within [Tompa et al., 2009, Gould et al., 2010]. These short linear motifs (SLiMs) are most abundant in

¹data from October 16th, 2013, checked on October 17, 2013

natively disordered proteins, but are also found in solvent accessible parts of globular domains, such as exposed loops [Davey et al., 2012, Fuxreiter et al., 2007]. The majority of SLiMs catalogued so far, are between 3 and 10 amino acids in length and in most cases with one or more highly variable residues [Neduva and Russell, 2005, Fuxreiter et al., 2007, Diella et al., 2008]. Their information content is therefore too poor to be statistically significant in protein sequence searches. True-positive SLiM prediction from sequence and alignment data is difficult to distinguish from randomly occurring false-positive motif candidates, as they occur in unstructured regions with a high degree of amino acid variation. A well-curated database for storing data on SLiMs is the eukaryotic linear motif resource (ELM), a computational resource developed by the European Molecular Biology Laboratory (EMBL). The ELM datasets are useful for bioinformatical characterizations and predictions for established and new short linear motifs. ELM was developed on the basis of the PROSITE data [Bairoch, 1991].

2.8. Media

2.8.1. Growth media for yeast

Media used for routine growth of *Saccharomyces cerevisiae* were “Yeast Peptone Dextrose” medium (YPD) medium, “Yeast Peptone Adenine Dextrose” (YPAD) medium, “Yeast Peptone Glycerol” (YPG) medium and “Yeast synthetic drop-out” (SD) medium.

Yeast complete medium “Yeast Peptone Dextrose” (YPD)

- 1 % yeast extract
- 2 % peptone
- 2 % glucose (dextrose)

Yeast complete medium “Yeast Peptone Adenine Dextrose” (YPAD)

- 1 % yeast extract
- 2 % peptone
- 0.004 % adenine hemisulfate
- 2 % glucose (dextrose)

Yeast complete medium “Yeast Peptone Glycerol” (YPG)

- 1 % yeast extract
- 2 % peptone
- 2 % glycerol

1. Introduction

Yeast synthetic drop-out medium (SD) (complete)

6.7 $\frac{g}{L}$ yeast nitrogen base without amino acids	40 $\frac{mg}{L}$ lysine
20 $\frac{mg}{L}$ adenine	10 $\frac{mg}{L}$ methionine
20 $\frac{mg}{L}$ arginine	60 $\frac{mg}{L}$ phenylalanine
10 $\frac{mg}{L}$ histidine	50 $\frac{mg}{L}$ threonine
60 $\frac{mg}{L}$ isoleucine	40 $\frac{mg}{L}$ tryptophan
60 $\frac{mg}{L}$ leucine	2 % glucose

As stock solution for routine use were held:

50 % (w/v) glucose
250× uracil
100× histidine
100× leucine
250× tryptophan
500× uracil

Solid growth media

For routine growth of *Saccharomyces cerevisiae* on agar plates, the respective medium is supplemented with 2 % agar.

2.8.2. Growth media for bacteria

Lysogeny Broth (LB) medium

0.5 % Yeast extract
1 % tryptone
1 % sodium chloride

LB + Kanamycin medium

0.5 % yeast extract
1 % tryptone
1 % sodium chloride
50 $\frac{\mu g}{mL}$ kanamycin, 50 $\frac{mg}{mL}$

LB + Ampicillin medium

0.5 % yeast extract
1 % tryptone
1 % sodium chloride
100 $\frac{\mu g}{mL}$ ampicillin, 100 $\frac{mg}{mL}$

SOC medium

0.5 % yeast extract
2 % tryptone
10 mM sodium chloride
2.5 mM potassium chloride
10 mM manganese(II) chloride
10 mM manganese(II) sulfate
20 mM glucose

2.9. Antibiotics

The following antibiotics were used when appropriate:

100 $\frac{mg}{mL}$ Ampicillin (1000 \times stock), used at 100 $\frac{\mu g}{mL}$
50 $\frac{mg}{mL}$ Kanamycin (1000 \times stock), used at 50 $\frac{\mu g}{mL}$

2.10. Protocol

Unless stated otherwise, *Saccharomyces cerevisiae* strains were grown at 30°C, *Escherichia coli* strains at 37°C.

3. Methods

3.1. Bioinformatical Methods

Bioinformatical analyses on *Saccharomyces cerevisiae* proteins were carried out using different tools provided by other groups in the internet (see table 3.1, 3.2 and 3.3). Data mining techniques and output data analyses were performed using shell and perl scripts generated and maintained by the author of this thesis.

3.1.1. Protein disorder prediction

Intrinsically unstructured or disordered proteins (IDPs or IUPs) are often referred to as to be natively unfolded and have a broad occurrence in living organisms. Though lacking specific three-dimensional structures — and instead, processing a large number of conformations under physiological conditions in the absence of a proper interaction partner — IUPs are involved in key biological processes such as cell cycle control, regulation, recognition, and signaling [Dunker et al., 2001]. These proteins are able to interact with and bind to a wide range of ligands, including partners such as proteins, membranes, and nucleic acids. Protein/protein interactions involve a combination of coupled binding and “folding-upon-binding” [Espinoza-Fonseca, 2009, Wright and Dyson, 2009]. Intrinsically unstructured regions have also been found to be important loci for alternative splicing [Romero et al., 2006] and for enzyme driven posttranslational modifications such as phosphorylation, methylation, or acetylation [Xie et al., 2007a, Gsponer et al., 2008]. While the opposite state of a protein being structured is rather simple to determine, the definition of being “disordered” or “unstructured” is still under discussion: A protein is “disordered” unless any structure is determined using methods such as X-ray crystallography, nuclear magnetic resonance (NMR), circular dichroism (CD), small-angle X-ray scattering. But absence of structural information is no good proof for an IUP. Therefore, there are different approaches to predict (and not verify) IUPs. Globular regions within *Saccharomyces cerevisiae* protein regions were predicted using locally installed versions of GlobPlot [Linding et al., 2003b] and IUPred [Dosztányi et al., 2005a, Dosztányi et al., 2005b]. Disorder prediction was performed using tools

3. Methods

such as DisEMBL [Linding et al., 2003a], RONN [Yang et al., 2005], FoldUnfold [Garbuzynskiy et al., 2004], FoldIndex [Prilusky et al., 2005] and IUPred [Dosztányi et al., 2005a, Dosztányi et al., 2005b]. The latter features algorithms for both long-range and a short-range disorder prediction as well as one for globularity. Protein regions predicted to have no structural characteristic were referred to as unstructured. All tools were used according to the respective developers' manuals.

Table 3.1. Bioinformatical web based methods used in this study for the globularity and disorder prediction of proteins.

FoldUnfold	http://www.bioinfo.protres.ru/ogu/	[Galzitskaya et al., 2006]

3.1.1.1. The GlobPlot method

IUPs generally have a biased amino acid composition, leading to the concept that secondary disorder prediction is based on propensities of each amino acid to occur in a distinct structural sequence context [Miyazawa and Jernigan, 1985, Sippl, 1990, Dunker et al., 2001, Linding et al., 2003b]. The idea behind IUPred is the hypothesis that the tendency for disorder can be described as

$$P = RC - SS$$

with the propensities for a given amino acid of being located rather in a 'random coil' (RC) or in any kind of 'secondary structured' (SS) region. These parameters were trained on protein data. These data sets comprised sequences of test bed proteins with determined secondary and random coil structure by Chou *et al.* [Chou and Fasman, 1974, Chou and Fasman, 1978], complemented by parameters [Deléage and Roux, 1987] and refined using data sets from the 'structural classification of proteins' (SCOP) database [Lo Conte et al., 2002a]. The frequencies RC and SS were calculated for each amino acid and published as Russel/Linding parameters. Additionally, Linding *et al.* developed a propensity scheme based on 'missing' or unresolved coordinates in proteins from the

3. Methods

protein data bank (PDB) [Westbrook et al., 2003]. Starting with the disorder propensity $P(a_i)$ of the i th amino acid a in a peptide of length L , a sum function Ω is introduced.

$$\Omega(a_i) = \sum_{j=1}^{i-1} \Omega(a_j) + \ln(i+1) \cdot P(a_i) \text{ with } i = 1, 2, \dots, L$$

The next mathematic steps towards the “Russel-Linding algorithm” comprise low-pass Savitzky-Golay filter smoothing [Press and Teukolsky, 2002] over Ω and estimation of the first order derivative of the plot using the TISEAN 2.1 “Nonlinear Time Series Analysis” package¹ [Hegger et al., 1999]. The disordered and globular sequence position are selected from regions where the derivative shows positive or negative values, respectively, over a minimum length.

Whereas the globular domain (GlobDoms) prediction was benchmarked against data from the SMART server², the lack of a unique disorder definition led to different approaches for disorder prediction algorithms for GlobPlot, including:

- The **Russel/Linding** algorithm as stated above.
- **B-Factors**. These isotropic temperature factors were considered for the C_α atoms in the polypeptide chains [Wampler, 1997, Parthasarathy and Murthy, 1999, Parthasarathy and Murthy, 2000]. When benchmarking with the SCOP database³ [Lo Conte et al., 2000, Lo Conte et al., 2002b], two different sets of B-factors were introduced as “2.0 standard deviation” and a more stringent variant “3.5 standard deviation”.
- **REMARK465**. This algorithm is based on missing residues from electron density or NMR data of solution structures in the Protein Database⁴ as stated above [Westbrook et al., 2003].

3.1.1.2. The DisEMBL method

The DisEMBL method [Linding et al., 2003a] is based on neural networks to allow the prediction of three different types of disorder:

- **loops/coils** as defined by the Dictionary of Secondary Structure of Proteins (DSSP) [Kabsch and Sander, 1983]. Loops are allowed to be part of structured protein regions (coils). The loops/coils algorithm is therefore not a unique requirement for disorder.

¹<http://www.mpipks-dresden.mpg.de/~tisean/>

²<http://smart.embl.de>

³<http://scop.mrc-lmb.cam.ac.uk/scop/>

⁴<http://www.pdb.org>

3. Methods

- **Hotloops** are loops with an increased degree in mobility. This characteristic is derived from the C_α temperature factors (B-factors) approach.
- **REM465**. This disorder definition is based on missing atom coordinates in X-ray solution structures, such as stored in the Protein Database.

3.1.1.3. The IUPred method

This method claims to take the physical explanation for the occurrence for disordered/intrinsically unfolded and ordered/globular protein regions into account. The basic idea is that in globular proteins, amino acids are able to overcome the loss of entropy upon folding by the gain of stabilizing inter-residue interaction energy [Garbuzynskiy et al., 2004]. On the contrary, IUPs are less capable to form sufficient inter-residue interactions with their spatial neighbours. Therefore, it is possible to discriminate between the two borderline states, globular and intrinsically unfolded, by estimating the potential of a polypeptide to form stabilizing contacts [Thomas and Dill, 1996]. Dosztanyi *et al.* showed that the sum of interaction energies is proportional to a quadratic expression in the amino acid composition [Dosztanyi et al., 2005b]. Additionally, the contribution to “globular” or “disorder” of a distinct amino acid depends not only on its chemical but also on its physical properties with respect to its potential interaction partner [Dosztanyi et al., 2005b].

The IUPred algorithm estimates the inter-residue energy between each pair of amino acids based on their C_β position [Dosztanyi et al., 2005a, Dosztanyi et al., 2005b]. The “heart of the method” is a 20×20 energy predictor matrix \underline{P} , whose elements P_{ij} had been trained on known globular structures. This position-specific method gives protein “likelihood of disorder” as probabilistic values in the range of 0 to 1. These values determine the borderline states, most residues correspond to values in between, complicating the determination of a complete sequence. The IUPred programme comes along with three different algorithms, “long (disorder)”, “short (disorder)” and “structured (regions)”, depending on the basic assumptions prior to parametrization.

3.1.1.4. The RONN method

This method is an evolution of a prediction method using a function neural network [Thomson and Esnouf, 2004] and is called “regional order neural network” (RONN) [Yang et al., 2005]. The Protein Data Bank and Molecular Structure Database (MSD) [Boutselakis et al., 2003] were taken as source for protein data. Trained on protein data sets comprising sequences with either mostly globular or mostly disordered or a mixture

3. Methods

of both folding states, multiple sequence alignments for each data set were generated. The observed differences in alignment scores are taken as a basis for the bio-based function neural network (BBFNN) method [Thomson et al., 2003, Yang and Thomson, 2005]. A sliding window technique gives ungapped sub-alignments training the BBFNN method to derive a receiver operator characteristic (ROC) for threshold determination. Query sequences are then evaluated against this threshold.

3.1.1.5. The FoldIndex method

This method was designed by Prilusky *et al.* and is based on the algorithm described by Uversky *et al.* [Uversky et al., 2000, Prilusky et al., 2005]. A formula for the net charge $|\langle R \rangle|$ of a given protein by its mean hydrophobicity $\langle H \rangle$ was introduced as

$$|\langle R \rangle| = 2.785\langle H \rangle - 1.151$$

with $\langle H \rangle$ calculated for each amino acid using the Kyte/Doolittle approximation and rescaled to values between 0 and 1 [Kyte and Doolittle, 1982]. “Natively unfolded” conformations are defined to have low mean hydrophobicity but a high net charge. Following this concept, interaction of natively unfolded protein regions with a binding partner affects $|\langle R \rangle|$ or $\langle H \rangle$ and therefore its folding state. The Fold Index[©] I_F^{KD} is then calculated as

$$I_F^{KD} = 2.785\langle H \rangle - |\langle R \rangle| - 1.151$$

and trained on experimental data from the Protein Database.

3.1.1.6. The FoldUnfold method

A similar approach is FoldUnfold [Galzitskaya et al., 2006, Mamonova et al., 2010]. Globular structures from solution structures were taken as basis for the calculation of mean packing density. An average number of neighbouring residues in an 8 Å range for each amino acid was taken into account with additional use of a sliding window average technique. This method was trained on both long globular and long disordered protein segments to derive an ROC for the threshold determination [Galzitskaya et al., 2006].

3.1.2. Multiple sequence alignments

In terms of evolution, biological functionality of proteins is preserved within a phylogenetic family of species. Such biologically relevant protein segments are less residue

3. Methods

variant than others and can be detected by comparative sequence analysis. The detection of highly conserved subregions within sequences is a central issue to computational biology [Lander et al., 1991, Karp, 1993].

3.1.2.1. Multiple sequence alignment construction and substitution matrices

Sequence alignments allow a comparison of closely related sequences, sharing functional or sequential homology. For a biologically realistic alignment, input sequences are filled up with gap characters to give a rectangular array of rows with different levels of residue variation with the help of a substitution matrix. These matrices describe the variation rate over evolution for a specific amino acid. Matrix values are calculated from manually curated collections of sequences with known phylogenetic background. Dayhoff *et al.* developed the point accepted mutation (PAM) substitution matrix from alignments of protein sequences which share at least 85% sequence identity [Dayhoff et al., 1978]. Substitution matrices, in general, comprise not only residue-against-residue scores, but also scores for the possibility to get ‘lost’ or to get ‘replaced’ by a gap character. Depending on the substitution rate and divergence time, different matrix values were calculated, defining several PAM matrices based on different sequence variations between PAM1 and PAM250. As PAM matrices fail for the construction of alignments between evolutionarily more divergent sequences, Henikoff and Henikoff derived their block substitution matrix (BLOSUM) series from blocks of locally aligned sequences within an overall alignment of less identical sequences, such as the BLOSUM62 matrix which is based on alignment segments of at least 62% sequence identity [Henikoff and Henikoff, 1992]. The overall similarity between all input sequences may be less. The best-fit alignment of sequences is the one with the maximum sum-of-pairs score (SP score) [Bacon

3. Methods

and Anderson, 1986, Gotoh, 1986, Murata et al., 1985, Altschul et al., 1989]. Alignment construction with more than two input sequences is a complex problem which is computational (too) expensive. First improvements in computational performance were achieved using techniques based on the Needleman-Wunsch algorithm for global alignments or the Smith-Waterman algorithm for local alignments [Needleman and Wunsch, 1970, Smith and Waterman, 1981]. Altschul *et al.* evolved dynamic programming algorithms [Sankoff, 1975] based on the Carrillo-Lipman algorithm for less computational cost [Carrillo and Lipman, 1988, Altschul et al., 1989, Lipman et al., 1989].

3.1.2.2. Progressive alignment tools: MUSCLE

MUSCLE, multiple sequence comparison by log-expectation, was developed by Edgar *et al.* as a construction tool for multiple sequence alignments (MSA) with progressive refinement [Hogeweg and Hesper, 1984, Feng and Doolittle, 1987]. In a first step, a distant matrix is calculated from input sequences using either k -mer counting for unaligned sequences [Edgar, 2004c] or the Kimura approach for aligned sequences [Kimura and Takahata, 1983]. Distant matrix clustering by the UPGMA (unweighted pair group method with arithmetic mean) [Prelić et al., 2006] hierarchical clustering method gives an initial phylogenetic tree [Sneath and Sokal, 1973, Sneath, 1977]. Sequences are transformed into profiles which are pair-wisely aligned following the tree in ‘root’ direction. Refinement via alternate tree and alignment construction with internal improvement evaluation gives a best-fit solution for a biologically relevant MSA.

3.1.2.3. Progressive alignment tools: MAFFT

Katoh *et al.* developed MAFFT (multiple sequence alignment based on fast Fourier Transform) as another MSA software similar to Edgar’s MUSCLE [Katoh et al., 2002]. MAFFT combines the construction of a rough initial MSA by the progressive method [Feng and Doolittle, 1987, Thompson et al., 1994, Katoh et al., 2002] with an iterative refinement method [Berger and Munson, 1991, Gotoh, 1993]. From the initial MSA an initial distant matrix is derived [Katoh et al., 2002] and a guide tree is constructed using an modified UPGMA method [Prelić et al., 2006]. Following that guide tree, the input sequences are aligned progressively [Feng and Doolittle, 1987, Thompson et al., 1994], which gives enough information for a new distant matrix [Edgar, 2004b, Katoh et al., 2002, Tateno et al., 1997]. The final MSA is obtained after alternate tree construction and immediate MSA refinement using an iterative method optimizing the weighted sum-of-pairs score (WSP) [Berger and Munson, 1991, Gotoh, 1993, Gotoh, 1995], an approx-

3. Methods

imate group-to-group alignment algorithm [Kato et al., 2002] and the tree-dependent restricted partitioning technique [Plyusnin and Holm, 2012].

3.1.2.4. Dialign-TX

The assessment of alignment quality is a crucial step in MSA construction. Further improvements in alignment accuracy came with the development of pair-hidden Markov models comprising genetic algorithms (HMM) [Notredame and Higgins, 1996], simulated annealing [Kim et al., 1994], profile HMM [Krogh, 1994, Eddy, 1995] and multiple segment-to-segment comparisons [Morgenstern, 1996]. These hierarchical methods are not error-prone in early interim steps when initial alignments are constructed and refined stepwisely. Consistency-based schemes such as Dialign act differently. Whereas other methods sum up substitution matrix scores and gap penalties, the Dialign approach employs P-values [Morgenstern et al., 1998]. Only those sequence regions are aligned that share statistically relevant similarities. In this study, a more elaborated version, Dialign-TX, was used [Subramanian et al., 2005, Subramanian and Kaufmann, 2008]. A combination of segment-based and progressive alignment algorithms constructs pairwise sequence alignments for all possible combinations for a guide tree. The pairwise sub-alignments are taken to build the overall alignment using anchor points [Morgenstern et al., 2006] and a vortex-cover algorithm [Clarkson, 1983].

3.1.2.5. ProbCons

HMM represent a further approach to MSA generation via combination of progressive methods with probabilistic consistency [Rabiner, 1989, Baldi et al., 1994, Krogh, 1994, Hughey and Krogh, 1996]. Probabilistic calculations achieve a stronger conservation signal and may therefore give a higher accuracy compared to other methods. Probabilistic consistency is provided by ProbCons with its pair-hidden Markov model-based progressive alignment algorithm. In a first step, posterior-probability matrices are calculated from all possible pairs of input sequences to construct initial pairwise alignments. Dynamic programming allows calculation of the expected accuracies for all aligned pairs. A probabilistic consistency transformation re-estimates those quality scores. Hierarchical clustering constructs a guide tree, starting with progressive methods. Further iterative refinement gives the optimal final alignment.

3.1.3. Computing sequence conservation from multiple alignments

A multiple sequence alignment comprises more or less phylogenetically related proteins to highlight sequence similarities as columns with higher degree of variation compared to others. Two different approaches have been tested in this study.

3.1.3.1. Computing sequence conservation from multiple alignments

The substitution matrix approach. Substitution matrices are mathematically derived from alignments of related sequences. They are constructed to display the evolutionary background as a basis for the residue variation within alignment columns. Therefore, substitution matrices such as BLOSUM [Henikoff and Henikoff, 1991, Henikoff and Henikoff, 1992] or PAM [Dayhoff et al., 1978] substitution matrices could be tested for alignment evaluation. Matrix values are regarded as amino acid/amino acid substitution scores. All alignment column elements are considered, whereas there are two approaches used in this study: First, all elements are regarded equal. Each residue-against-residue substitution is scored once and summed up to give the substitution score. Second, one sequence is taken as basis, in this case the *Saccharomyces cerevisiae* sequence. All possible substitutions are scored according to ‘replacements’ of the specific *Saccharomyces cerevisiae* amino acid. The pairwise substitution scores among the other sequences are ignored.

The information theoretical SeqLogo approach. This web-based tool graphically shows the information content of input multiple sequence alignments. The information theory behind is based on the works of Shannon *et al.* [Shannon, 1948, Schneider et al., 1986, Schneider and Stephens, 1990].

3.1.3.2. Information theory as mathematical background of the SeqLogo approach

Information theory based on the works of Shannon *et al.* and Pierce *et al.* give a mathematical basis for the description and evaluation of multiple sequence alignments at large scale [Shannon, 1948, Pierce et al., 1980].

For a defined ensemble with 4 nucleotides or 20 amino acids, respectively, the uncertainty H at an alignment position l is determined as $H(l) = -\sum_{b=a}^t f(b,l) \cdot \log_2 f(b,l)$ with $f(b,l)$ the frequency of residue b at position l . The total amount of information at position l , $R_{seq}(l)$, is

$$R_{seq}(l) = S_{max} - S_{obs}(l) = \log_2 X - (H(l) - e(n))$$

with S_{max} the maximum uncertainty of the ensemble, $S_{obs}(l)$ the observed uncertainty at position l , X the available number of residues in the ensemble and $e(n)$ as a correction factor for n -sized alignments of few sequences. Such a small-sample correction is approximated as

$$e(n) = \frac{1}{\ln 2} \cdot \frac{X - 1}{2n}$$

For protein and nucleotide sequences the information content for a given position is

$$R_{seq}^{prot}(l) = \log_2 20 - (H(l) - e(n))$$

and

$$R_{seq}^{nucl}(l) = \log_2 4 - (H(l) - e(n)) = 2 - (H(l) - e(n))$$

Schneider *et al.* showed that the information approach is able to distinguish binding sites from the rest of the genome [Schneider et al., 1986] and evolved the graphical SeqLogo application from information theory [Schneider and Stephens, 1990]. SeqLogo was developed by Crooks *et al.* in 2004 as a web-based graphical application [Crooks et al., 2004].

3.1.3.3. The sliding window average technique

The sliding average techniques provides a mathematical calculation to average data points. It performs a series of subset averaging operations. The result is assigned to the subset's center position. The next averaging operation is performed with a subset 'shifted forwards'.

The sliding average technique is applied to determine a motif's 'absolute', 'relative' and 'background' conservation from conservation scores.

3.2. Genetic Techniques

All genetic-biological works comprised the amplification of oligonucleotides in polymerase chain reactions (PCR) on *Saccharomyces cerevisiae* DNA as a template [Kleppe et al., 1971, Saiki et al., 1985]. Multiplication of genetic material was performed in bacterial strains of *Escherichia coli* prior to isolation from that strains. Verification and transformation of those constructs into *Saccharomyces cerevisiae* was performed for further investigations.

3.2.1. Preparation of plasmid DNA from *Escherichia coli*

Small-scale and large-scale bacterial plasmid preparations were performed using the plasmid isolation kits from Qiagen according to the manufacturer's instructions for high-copy number plasmids.

Escherichia coli cells were cultivated in lysogeny broth medium supplemented with the appropriate amount of antibiotic at 37°C for at least 14 hours while shaking at a constant rate of 220 rpm. The Qiagen "QIAprep" miniprep procedure uses the modified alkaline lysis method of Birnboim and Doly [Birnboim and Doly, 1979]. Bacterial cells are lysed in sodium hydroxide/SDS buffer in the presence of RNase A. One-step neutralization and adjustment to high-salt binding conditions of the lysate prepares the adsorption of plasmid DNA on silica membranes. After washing, the DNA is eluted from the membranes under low-salt conditions.

3.2.2. Quantitation of nucleic acids

DNA concentrations and purities of aqueous solutions were determined spectrophotometrically by measuring their absorbance at 260 nm. An absorbance (A_{260}) of 1 corresponds to 50 $\frac{\mu\text{g}}{\mu\text{L}}$ of double-stranded DNA and 40 $\frac{\mu\text{g}}{\mu\text{L}}$ of RNA or single-stranded DNA. The ratio $\frac{A_{260}}{A_{280}}$ corresponds to the sample purity. Ratios between 1.8 and 2.0 are regarded highly pure [Sambrook et al., 1989].

3.2.3. Generation and transformation of competent *Escherichia coli* cells

Chemically competent bacterial *Escherichia coli* cells were transformed according to the respective cell strain's manufacturer's protocol. With slight variations in the protocols, all used strains were processed as follows: Cells were kept on ice after removing from the -80°C storage. After adding 2–5 μL of miniprep isolated plasmid DNA to the cells, the cells were swirled and still kept on ice for 30 minutes. Cell tubes were heat shocked

3. Methods

at 42°C for 45 seconds, kept on ice for 2 minutes and the complete cell material streaked on lysogeny broth media plates supplemented with appropriate antibiotic. The plates were incubated overnight at 37°C.

3.2.4. DNA manipulations

Polymerase chain reaction were performed on BioRad Reaction Cyclers using DNA polymerases “Phusion high fidelity polymerase” from New England Biolabs, Cambridge, UK, and “Taq DNA polymerase” from Invitrogen with their respective reaction mixes. Restriction enzymes were purchased from New England Biolabs, Cambridge, UK. All enzymes and reagents were used according to the manufacturers’ instructions. A common PCR programme set-up is given in table 3.4. A more detailed description of PCR steps is given in section 3.2.8. Denaturation temperature and duration depend on the polymerase used, whereas annealing values depend on primer characteristics. Elongation time is determined by the polymerase used and the desired amplicon size.

Typical reaction mixes contain:

component	final concentration
nuclease free water	-
buffer	1×
dNTP mix, 10mM	200 μ M
forward primer 10mM	0.5 μ M
reverse primer 10mM	0.5 μ M
template DNA	less than 250 ng
DNA polymerase	depending on the manufacturer’s instructions

Table 3.4. Typical program set-up for a Polymerase Chain Reaction (PCR).

Step	Temperature	Duration	Description	Repetitions
1	92-96°C	30 sec to 2 min	initial denaturation	
2	92-96°C	1 sec	denaturation	25-30×
3	52-60°C	15 to 30 sec	annealing	
4	72°C	30 - 60 $\frac{\text{sec}}{1\text{kb}}$	elongation	
5	72°C	10 min	final elongation	

3. Methods

3.2.5. DNA gel electrophoresis

Standard DNA gel electrophoresis was performed in agarose gels after PCR or restriction [Sambrook et al., 1989]. For resolution of DNA fragment sizes between 0.5 and 5 kb 1 % (w/v) agarose in 1× TAE buffer was used. DNA was visualized by adding ethidium bromide (UV light) or Sybr[®] Safe from Invitrogen (blue light) to the agarose gel, both according to the manufacturer’s instructions. For gel extraction, the respective light sensitive band was cut out from the gel and the DNA was purified using the Qiagen Gel extraction kit.

1× TAE buffer	6× DNA loading buffer
0.04 M Tris-HCl, pH 8.0	0.25 % (w/v) bromophenol blue
0.114 % acetic acid	0.25 % (w/v) xylene cyanol
1 mM EDTA	15 % Ficoll

3.2.6. Generation and transformation of competent *Saccharomyces cerevisiae*

A 50 mL culture was inoculated at an optical density of OD_{600}^{25} of 0.2 from a fresh overnight culture and incubated at 30°C while shaking until OD_{600}^{25} of 0.6 to 0.8. Cells were harvested at 4000 rpm for 5 minutes and washed once with 100 mM aqueous Lithium acetate solution. The cell pellet was resuspended in 500 μ L of 100 mM aqueous Lithium acetate solution and aliquoted in 50 μ L portions. After brief centrifuge spin the supernatant was removed, the pellet resuspended in “transformation mix” solution. The suspension was vortexed thoroughly and incubated at 30°C for 30 minutes. After heat shock at 42°C for 40 minutes, the cells were collected by centrifugation at 4000× g for 2 minutes, removing the supernatant and washing once with 1 mL of sterile water, resuspended in sterile water and plated on selective synthetic drop-out agar plates. Colonies of transformed cells should be isolated after incubation at 30°C for 2 – 4 days.

Transformation mix

240 μ L	50 % (w/v) PEG-3350
36 μ L	1M Lithium acetate, aqueous
5 μ L	single stranded calf thymus DNA, 10 $\frac{\mu$ L}{mL}
0.1 – 10 μ g	plasmid DNA
70 mL	sterile water

3. Methods

3.2.7. Preparation of genomic DNA from *Saccharomyces cerevisiae*

Prior to the preparation step, *Saccharomyces cerevisiae* colonies were purified by dilution plating onto appropriate nutrient medium to obtain isolated colonies. A single colony is then inoculated shaking in liquid medium overnight at 30°C. Genomic DNA preparation is then processed using the Qiagen Puregene “Yeast/Bact. kit” according to the manufacturer’s instructions.

3.2.8. Sanger DNA sequencing

Sequencing of double stranded DNA was done by the dideoxynucleotide method of Sanger using the “BigDye Terminator V.3.1” kit from Becton-Dickinson and the thermocycler ABI-Prism 3100 from Applied Biosystems [Sanger et al., 1977]. 500 ng of plasmid DNA were mixed with ready-to-use sequencing mix and 5 pmol of sequencing primers from table 2.4. PCR were performed according to the sequencer’s instructions (see tables 3.5, 3.6(a)). The procedure begins with an pre-heating step to 96°C for 5 minutes (step 1). The cyclic steps comprise: Denaturation of the nucleic acid chain at 96°C for 30 seconds (step 2), annealing of primers to the target sequence at 50°C for 15 seconds (step 3) and extension of the complementary nucleic acid strand by the polymerase at 60°C for 4 minutes (step 4). A final extension step for 10 minutes ensures all remaining single-stranded DNA strands are fully extended (step 5). The processing of the samples was done after Exo-SAP PCR clean-up (see table 3.6(b)) in the central sequencing laboratory of the Cologne Center for Genomics⁵ (CCG).

Table 3.5. Sanger sequencing PCR protocol using the “BigDye Terminator V.3.1” kit from Becton-Dickinson.

Step	Temperature	Duration	Repetitions
1	96°C	5 min	
2	96°C	10 sec	
3	55°C	5 sec	32×
4	60°C	4 min	
5	60°C	10 min	

3.2.9. The PCR epitope tagging technique

As the *Saccharomyces cerevisiae* genome is fully sequenced [Goffeau et al., 1996], PCR-techniques have come up which allow gene-targeting for a easy-to-proceed functional

⁵Cologne Center for Genomics, Weyertal 115b, 50931 Cologne, Germany.

3. Methods

Table 3.6. BigDye[®] Terminator reaction mix composition (a) and Exo/SAP clean-up protocol (b).

(a)		(b)	
	Volume		Volume
BigDye [®] Terminator v1.1/v3.1	0.25 μL	PCR product	7.0 μL
5 \times BigDye sequencing buffer	2.25 μL	ExoI (20 $\frac{U}{\mu\text{L}}$)	0.15 μL
Primer, 10 mM	0.25 μL	SAP (1 $\frac{U}{\mu\text{L}}$)	0.9 μL
PCR template	2–10 ng per 100 bp	H ₂ O	1.95 μL
H ₂ O	1.95 μL		

ExoI: Exonuclease I, 15000 U from Neo Lab. SAP: Shrimps alkaline phosphatase, 500 U from Promega.

analysis of genes [Baudin et al., 1993, Wach et al., 1994]. With the PCR epitope tagging (PET) technique gene targeting for deletion, replacement or insertion of heterogenous DNA at a discrete locus on the genome is feasible [Knop et al., 1999, Longtine et al., 1998, Janke et al., 2004].

In the first step of the protocol described, the desired module is PCR amplified using S2- and S3-primers from table 2.4. These primers were designed to allow cassette amplification from the template plasmid. That cassettes comprise a selectable and an epitope tag. The cassette is flanked by homologous sequences with the gene of interest (GOI) in the target DNA (see table 2.4). Upon transformation into *Saccharomyces cerevisiae* strain JD47–13C after the Lithium acetate method (section 3.2.6), homologous recombination of the PCR fragment into the gene locus leads to in-frame fusion of the GOI and epitope tag [Schiestl and Gietz, 1989].

3.2.10. The site-directed mutagenesis technique

Site-directed mutagenesis of plasmid DNS was conducted using the “QuikChange[®] Lightning Site-Directed Mutagenesis Kit” from Stratgene, UK, following the manufacturer’s instructions on primer design, reaction mix composition, reaction cycling conditions and reaction mix clean-up after cycling. Direct usage of the reaction mix for transformation into bacterial XL10-Gold[®] super-competent cells gave the desired transformants on lysogeny broth medium supplemented with appropriate antibiotic. Plasmids were isolated from transformants and digested with suitable enzymes to give a unique restriction pattern of bands on a agarose gel. Sanger sequencing confirmed the plasmid sequence.

3.2.11. The Gateway™ cloning technique

Some of the plasmid construction works were performed using the Gateway™ cloning technique. This technique is based on the site-specific recombinase system of bacteriophage lambda (λ). It facilitates the integration of λ genome into the *Escherichia coli* chromosome and the switch between lytic and lysogenic pathways [Ptashne, 1992]. Lambda-based recombination involves the DNA recombination sequences and proteins that mediate the recombination reaction. Recombination only occurs between the *att* sites, specific attachment sites on interacting DNA molecules. DNA segments flanking the *att* sites are interchanged in a way that the *att* sites are converted to hybrid sequences from parental vectors during the recombination step. The *att* sites have been engineered by the manufacturer to ensure specificity of the recombination reactions to maintain sequence orientation, to minimize secondary structure formations and to establish an incompatible sets of *att* site pairs: *attB1/attP1*, *attB2/attP2*, *attP1/attL1*, *attP2/attL2*. The actual cross-over reaction itself is catalyzed by a mixture of enzymes that bind to specific *att* sequences [Stark et al., 1989, Landy, 1989]: The “BP” reaction is mediated by bacteriophage λ integrase (Int) and *Escherichia coli* integration host factor (IHF) proteins. Reaction only occurs between bacterial *attB* and phage *attP* sites to specifically give the *attL* sites. These sites can be recombined in a second reaction to give the corresponding *attR* sites in an “LR” reaction. In this step, bacteriophage λ Int and excisionase (Xis) proteins together with *Escherichia coli* IHF are the mediators. The manufacturer provides prepared master mixes with the respective clonase enzyme/protein combination for both BP- and LR-reaction.

The Gateway™ cloning protocol

The first step for using this technique is the PCR amplification of the desired DNA fragment together with appropriate *attB* sites. The primers were designed according to the manufacturer’s instructions (in 5′ → 3′ direction):

attB1 forward oligo: GGGG ACAAGTTTGTACAAAAAAGCAGGCT TC X⁶

attB2 reverse oligo: GGGG ACCACTTTGTACAAGAAAGCTGGGT C X⁶

The manufacturer provides a number of entry vectors. In this study, pDONR™221 was exclusively used for BP reactions. Its features are: a chloramphenicol resistance gene located between the *attP* sites for counter-selection, a *ccdB* gene located between the

⁶18–25 gene-specific nucleotides at the 3′ end.

3. Methods

two *attP* sites for negative selection, kanamycin resistance for selection in *Escherichia coli* and pUC origin for replication and maintenance of the plasmid in *Escherichia coli*. The BP reaction was set up as described in table 3.7 and run overnight at 25°C.

Table 3.7. The Gateway™ BP reaction mix used in this study.

Component	Volume
PCR with flanking <i>attB</i> sites	1.0 – 7.0 μL
pDONR™ 221 (150 $\frac{\text{ng}}{\mu\text{L}}$)	1.0 μL
BP clonase	0.25 μL
TE buffer	to 8.25 μL

BP clonase, Sigma-Aldrich

Transformation of the unpurified reaction solution into *Escherichia coli* strain XL1-blue gave the desired transformants on lysogeny broth media plates supplemented with kanamycin after incubation overnight at 37°C. The manufacturer offers a variety of destination vectors. In this study, pACT2™ with ampicillin selectable marker was used as destination vector together with the plasmid from the previous BP reaction. The LR reaction was set up as described in table 3.8 and run overnight at 25°C.

Table 3.8. The Gateway™ LR reaction mix used in this study.

Component	Volume
entry clone from previous BP reaction with <i>attP</i> sites	1.0 – 10.0 μL
destination vector (150 $\frac{\text{ng}}{\mu\text{L}}$)	2.0 μL
LR clonase reaction buffer, 5×	3 μL
LR clonase	0.25 μL
TE buffer	to 15.25 μL

LR clonase, Sigma-Aldrich

Transformation of the unpurified reaction solution into *Escherichia coli* strain XL1-blue gave the desired transformants on lysogeny broth media plates supplemented with ampicillin after incubation overnight at 37°C.

3.2.12. Preparation of crude extracts from *Saccharomyces cerevisiae*

Cells were routinely harvested from liquid cultures by centrifugation at 4000 rpm and washed once with water. Depending on further purpose, one of the following methods for protein extraction was used:

3. Methods

Boiling For direct use in denaturing polyacrylamide gel electrophoresis (PAGE), cell pellets were simply resuspended in SDS-PAGE sample buffer and lysed by incubating at 100°C for 5 minutes. Unless stated otherwise insoluble cell debris was spun down and the supernatant was used for PAGE. Routinely, crude extracts from 0.5 to 1 OD₆₀₀²⁵ units per sample were loaded onto the gel.

Glass bead extraction (I) The following steps were all carried out at 4°C. After harvesting, cells were resuspended in lysis buffer including a protease inhibitor cocktail (complete protease inhibitors, Roche Diagnostics, Mannheim, Germany) and acid washed glass beads (Ø 0.45 mm) were added approximately in a 1:1 ratio. The sample was vortexed for 5 minutes at 4°C and then centrifuged at 16000×g for 10 minutes, the supernatant transferred to fresh tubes and used as crude extracts.

1× Lysis buffer

50 mM HEPES, pH 7.5
150 mM sodium chloride
1 % (v/v) triton-X-100
5 mM EDTA

Sample buffer

62.5 mM Tris
2% SDS
10% glycerol
0.002% bromophenol blue
adjust to pH 6.8

3.2.13. Preparation of crude extracts from *Escherichia coli*

Glass bead extraction (II) Cells were routinely harvested from liquid cultures by centrifugation at 10,000 rpm and washed once with water. The next steps were all carried out at 4°C. After harvesting, cells were resuspended in lysis buffer including a protease inhibitor cocktail (complete protease inhibitors, Roche Diagnostics, Mannheim, Germany) and acid washed glass beads (Ø 0.10 – 0.11 mm) were added approximately in a 1:1 ratio. The sample was vortexed for 5 minutes at 4°C and then centrifuged at 16000× g for 10 minutes, the supernatant transferred to fresh tubes and used as crude extracts.

3.2.14. SDS polyacrylamide gel electrophoresis

For protein separation, one-dimensional polyacrylamide gel electrophoresis (PAGE) under denaturing conditions was applied [Laemmli et al., 1970]. Gel compositions are given in tables 3.9 and 3.10. Usually, a acrylamide content of 10% was used. Samples were loaded after boiling in Laemmli loading buffer (LLB) for 5 minutes. Gel runs were

3. Methods

performed in Laemmli running buffer (LRB). Applied current and running time was applied according to gel size and expected sample masses to be resolved.

Reagents for SDS-PAGE

3. Methods

3.2.15. Western blot analysis

After SDS gel electrophoresis proteins were transferred to a polyvinylidene fluoride (PVDF) membrane from Millipore by semi-dry blotting at 240 mA for 1 – 3 hours depending on the size of proteins detected. After transferring, the proteins were fixed to the membrane by boiling in water for 30 minutes. The membrane was incubated in blocking solution (3 % (w/v) dry milk powder in PBST) for 45 minutes, followed by one hour incubation with primary antibody diluted in blocking solution. After two washing steps in PBST and SAIS for 5 minutes and another blocking for 10 minutes, the membrane was incubated with the secondary peroxidase coupled antibody. After several washing steps with PBST and SAIS, the membrane was washed in a final step with PBS and incubated in 'lumilight plus western blotting reagent' from Roche. X-ray films from Fuji were exposed for documentation.

1 M sodium chloride
10 mM disodium hydrogenphosphate
0.5 % (w/v) tween-20

3.2.16. The Yeast Two-Hybrid assay

Protein-protein interactions (PPI) were detected *in vitro* using the yeast two-hybrid technique (Y2H) [Fields and Song, 1989, Chien et al., 1991]. Physical interaction between two proteins is detected linking interaction to an observable phenotype. The Gal4 transcription factor is divided into a activating (AD) and a binding (BD) domain and is only functional when those two domains are placed in close proximity. Fusing proteins either to AD and BD, transcription only occurs when interaction between the distinct proteins serves as linker for AD/BD interaction which then enables transcription of the reporter HIS and ADE genes and the observable phenotype. That transcriptional assay utilizes a genetically modified yeast strain like AH109 or PJD69-4A, in which the biosynthesis of

3. Methods

certain nutrients is lacking. In these strains, three reporter genes ADE2, HIS3 and MEL1 (or lacZ) under the control of distinct GAL4 upstream activating sequences (UAS) and TATA boxes are used. Genes, encoding the SUMO-interacting candidate proteins from the bioinformatical prediction screen, were HA-tagged and fused to the Gal4-activating domain, while SMT3 variants SMT3, SMT3 Δ 97, SMT3 Δ 97x3, SMT3 Δ 97x4, were fused to the Gal4-binding domain. Both Gal4 activating and Gal4 binding plasmids were simultaneously transformed into PJ69–4A and AH109, respectively, transformants selected on YP(A)D⁷ plates lacking leucine and tryptophane. After replica streaking onto SD-LW plates, equal aqueous solutions from cell dilutions corresponding to 10 OD₆₀₀²⁵ were spotted onto synthetic drop-out media plates additionally lacking histidine, histidine and variant amounts of 3-amino-1,2,4-*H*-triazole (3-AT), and adenine, respectively [Fields, 1993, Joung et al., 2000, Fields, 1993]. Colony growth on these selective media plates is regarded as a measure of interaction between Gal4 activating and Gal4 binding domain and, therefore, between fused assumed interactors.

3.2.17. The GST-Pulldown assay

To verify the results from the yeast two-hybrid assays, GST pulldown assays were performed with new designed constructs as described in Kristina Uzunova’s PhD thesis [Uzunova, 2006]. *Escherichia coli* strain BL21(DH3) was transformed with plasmids, expressing either GST or GST-SUMO. Proteins as a putative interaction partner were genetically 6 \times histidine tagged using the protocol developed by Knop *et al.* [Knop et al., 1999, Janke et al., 2004]. Protein expression was induced for 4 – 5 hours at 37°C upon isopropyl-1-thio- β -D-galactopyranoside (IPTG) addition. Cells corresponding to an optical density of 10 OD₆₀₀²⁵ were harvested by centrifugation at 14000 rpm for 5 minutes and resuspended in 450 μ L extraction buffer. Mechanical rupture after the glass bead lysis protocol and removal of cell debris by centrifugation at 14000 rpm at 4°C for 10 minutes gave the GST- and GST-SUMO crude extracts. Epitope tagged proteins were obtained upon culturing respective yeast strains in YPD liquid media at 30°C for 3 hours. With an OD₆₀₀²⁵ of 0.6 – 0.8, cells corresponding to an OD₆₀₀²⁵ of 10 were harvested by centrifugation at 4000 rpm for 5 minutes, mechanically ruptured after the glass bead protocol (section 3.2.13). 80 μ L of a 1:1 slurry of glutathion-sepharose CL-4B resin (Amersham Pharmacia Biotech, Piscataway, NJ, USA) was inverted with an equal amount of extraction buffer for 1 hour at 4°C, washed three times with 100 μ L extraction buffer. Then 100 μ L of GST containing crude extract were applied to the beads,

⁷AH109 is a adenine deficient yeast strain. Addition of adenine to growth media is recommended.

3. Methods

inverting the tubes for 2 – 4 hours at 4°C. After centrifugation for 3 seconds at 800 rpm at 4°C and washing once with 100 μ L extraction buffer, 100 – 200 μ L of the yeast crude extracts were applied to the Sepharose beads inverting the tubes for 2 – 4 hours at 4°C. The beads were washed at least once with extraction buffer and resuspended in sample buffer and incubated at 100°C for 5 minutes.

extraction buffer

150 mM sodium acetate
2% SDS
10% glycerol
0.002% bromophenol blue
adjust to pH 6.8

3.2.18. Two-step gene replacement

Replacement of a wild-type gene with a mutant allele at the endogenous locus was performed as using the two-step gene replacement technique [Widlund and Davis, 2005]. The mutant variant was PCR amplified and ligated into the shuttle vector pRS306 bearing an URA3 marker. Transformation into *Escherichia coli* strain DH5 α onto synthetic drop-out plate medium supplemented with the respective antibiotic and 5-bromo-4-chloro-3-indolyl- β -D-galactopyranoside (X-Gal) allowed blue/white screening for increased transformation efficiency. Plasmids were isolated as colorless transformants and digested with suitable enzymes to give a unique restriction pattern of bands on an agarose gel. Sanger sequencing confirmed the correct sequence of that integratable plasmid. Its linearization with a uniquely cutting restriction enzyme BamHI leads to homologous recombination to the endogenous gene locus as a tandem array of wild-type and mutant allele flanking the URA3 selectable marker. Selection/counter-selection on YPD plate medium supplemented with 0.1% 5-fluoro-orotic acid (FoA) leads to reduction of that URA3 marker and flanking sequence repeats by mitotic recombination to give the mutant variant of the wild-type gene of interest. After purification of the mutant yeast strain by dilution streaking from single colonies onto YP/Glycerol plates and replica plating onto SD/FoA medium, the mutant yeast strain was verified by both PCR amplification using primers from table 2.4, restriction at the site of mutagenesis and sequencing of the amplicon.

4. Results

Short linear motifs (SLiMs) in general, or SUMO interacting motifs (SIMs) in specific terms, are hard to handle with bioinformatical methods (section 1.6). These methods are originally designed and trained on longer protein domains. Short motifs can be seen as special types of domains.

The following paragraphs describe the bioinformatical analysis of established SIMs and their flanking regions, with the aim to derive characteristics that can be used to discriminate functional SIMs from spurious SIM-like sequences. Subsequently, these characteristics are used in a proteome-wide screen for novel SIMs in the budding yeast *Saccharomyces cerevisiae*. In section 4.5, the same set of criteria is used for the detection of another short motif with SIM-like characteristics: the AIM motif that mediates binding to Atg8 (section 1.4.3).

4.1. General aspects for a bioinformatical prediction of SUMO interacting motifs

Protein sequence data was obtained from mining sources such as the Broad Institute of the Massachusetts Institute of Technology (MIT) and the Harvard University and the U.S. Department of Energy Joint Genome Institute (DOE JGI, or JGI). Retrieved data was processed for further use as database for bioinformatical applications. Unless stated otherwise, all applications used in this study were programmed by the author of this study.

4.1.1. SUMO interacting motifs belong to one of the three consensus patterns

SIM sequences belong to one of the three consensus patterns SIMa, SIMb and SIMr [Uzunova et al., 2007]. These three SIM consensus patterns form the basis for the discovery of novel SIM instances. A consensus search within a *Saccharomyces cerevisiae* sequence database yields a large number of retrieved motifs (table 4.2). Variations in the search pattern change the number of retrieved motifs. The exact definition of a sequence

4. Results

pattern is important for the performance of a pattern-based database search. Too restrictive consensus patterns exclude biologically relevant motifs. With less stringent patterns, too many false-positive motif candidates are retrieved. For both borderline cases, the number of SIM-like protein sequences is much higher than the number believed to be relevant.

Table 4.1. SIM sequence characteristics as criterion in a bioinformatical prediction approach.

SIMa	Four hydrophobic residues, usually isoleucine, leucine, valine or methionine, but with a more variant third position compared to the others. At least two “acidic” termed amino acids such as aspartic acid or glutamatic acid follow that stretch. A possible consensus pattern is [ILVM] [ILVM] . [ILVM] [SDE] [SDE].
SIMb	Only few motif sequences are known for this consensus type. The consensus pattern is the most stringent one with a core comprising the amino acids valine, isoleucine, aspartic acid, leucine and threonine with more residue variability at the third position. A consensus pattern can be described as [PVILMT] [ILVM] DLT.
SIMr	This consensus pattern has only been observed in RanBP2, Elg1 and recently shown in Rad18 [Pichler et al., 2002, Hecker et al., 2006, Parnas et al., 2010, Parker and Ulrich, 2012]. The SIMr consensus pattern has close similarity to the one for SIMa, but in a reverse orientation. A possible consensus pattern is [DES] [DES] [ILVM] . [ILVM] [ILVM].

Table 4.2. Consensus patterns for SIMa, SIMb and SIMr for pattern-based *Saccharomyces cerevisiae* protein sequence screens.

consensus type	consensus pattern	number of sequence strings	number of different proteins
SIMa	[ILVM] [ILVM] . [ILVM] [SDE] [SDE]	1,555	1,264
	[PILVM] [ILVM] . [ILVM] [SDE] [SDE]	1,912	1,495
	[PILVM] [ILVM] . [ILVM] [SDE] [SDE] [SDE]	387	361
SIMb	[PVILMT] [ILVM] DLT	36	36
SIMr	[DES] [DES] [ILVM] . [ILVM] [ILVM]	8,502	1,159
	[DES] [DES] [ILVM] . [ILVM] [PILVM]	1,760	1,387
	[DES] [DES] [DES] [ILVM] . [ILVMF] [ILVMF]	524	470

4.1.2. Four criteria for evaluation of database screen results for new SUMO interacting motifs

The number of motif candidates retrieved by the consensus pattern search is much higher than the expected number of biologically relevant SIM instances. There are more criteria to be defined as a measure for relevance from such a search. Multiple sequence alignments (MSA) of established SUMO interacting proteins show additional criteria (table 4.3):

Table 4.3. Four criteria for a reliable detection of relevant SUMO interacting motifs.

consensus adherence	Established SUMO-interacting motifs can be classified to one of the three consensus types SIMa, SIMb and SIMr (table 4.1). As such, any new SIM is expected to fulfill one of those consensus criteria.
absolute conservation	Functional motifs are under evolutionary constraints. Any variation in motif sequence only occurs in tight limits and in accordance with its interaction partner. Therefore, new SIMs are also expected to be conserved, at least over moderate evolutionary distances.
relative conservation	By contrast to functional SIMs, the flanking regions are typically not constrained. Therefore, new SIMs are expected to be better conserved than their flanking regions.
structural context	Additionally, SIMs occur outside globular structures. A possible explanation may be that SIMs have to be in flexible protein regions. Therefore, new SIMs are expected to reside in regions that are predicted to be unstructured, or at least not predicted to be globular.

4.1.3. Comparison of different disorder prediction tools for a bioinformatical SIM detection procedure

There are several tools for predicting unfolded ('disorder') regions in proteins, usually with different concepts of what constitutes an unfolded region. To investigate which of these tools is suited for enriching functional motifs, a number of web-based prediction tools was tested such as DisEMBL, GlobPlot, IUPred, FoldUnfold, FoldIndex and RONN (section 3.1.1) [Linding et al., 2003a, Linding et al., 2003b, Yang et al., 2005, Garbuzynskiy et al., 2004, Prilusky et al., 2005]. The test bed of proteins comprised the sequences of the human proteins Daxx and Prrg3 and *Saccharomyces cerevisiae* protein Wss1 [Biggins et al., 2001, Hitt and Wolf, 2004, Lin et al., 2006]. They contain motifs of different

4. Results

classes (table 4.4). A disorder prediction method is considered as suitable if it places short functional motifs in disordered context while predicting folded domains as non-disordered. Globularity prediction methods are used as an additional measure where the prediction of non-globularity is interpreted as being potentially unstructured.

Table 4.4. Motifs in Daxx, Prrg3 and Wss1 proteins for a performance test of bioinformatical disorder and globularity prediction tools. A bioinformatical evaluation of protein sequences whether a distinct protein region is unfolded is a crucial step towards a reliable SIM detection. These proteins and motifs serve as test bed for several prediction tools.

protein	coordinates	motif	description	reference(s)
Daxx	7–15 733–740	IIVLDD IIVLSDS	SIMa	[Lin et al., 2006]
Prrg3	79–101 191–194 216–219	AMYVVVPLLGV- ALLIVIALFIIW PPSY PPKY	helical domain PY box PY box	[Kulman et al., 2001]
Wss1	209–219 247–251 265–269	RELAFAAER VVILDD VIDLT	VIM SIMa SIMb	[Hitt and Wolf, 2004] [Biggins et al., 2001]

IUPred was used with parameters favoring the detection of short (IUPred ‘short’) and longer unstructured regions (IUPred ‘long’). These algorithms and DisEMBL with its parameters for ‘LOOPS’ and ‘HOTLOOPS’ gave the best results. RONN, FoldIndex and FoldUnfold predicted longer disordered regions. The criterion of a SIM’s structural context is less suitable for short motifs with these methods. GlobPlot shows good results for the globularity prediction for the test motifs. This first overview addressed a range of different motifs, not all of which are guaranteed to reside within unstructured regions. The different test motifs are not all located in unstructured regions.

Therefore, a second round of evaluation was performed. The new test bed comprised the SIPs Daxx, RNF4, Fir1, Uba2, Slx5, Nis1, Siz1 and Uls1 (table 1.1) [Johnson and Gupta, 2001, Pichler et al., 2002, Hannich et al., 2005, Li et al., 2007b, Uzunova et al., 2007, Sun et al., 2007]. The tested tools were as before.

FoldUnfold predicts the SIM hydrophobic part as folded. Therefore, this approach is not helpful for this study. FoldIndex gives slightly better results in this test. It yields larger segments of disorder covering the established SIMs. GlobPlot ‘B-factors 2.0 std. dev.’ and DisEMBL ‘LOOPS’ tend to give nearly identical results. The performances of the IUPred disorder tool are better with SIMs compared to the results from the previous test with shorter motifs only. The IUPred disorder server with both its ‘IUPred short’ and ‘IUPred long’ algorithms give again good results. Best disorder prediction results are

4. Results

obtained with a combination of these three methods, GlobPlot ‘B-factors 2.0 std. dev.’, IUPred ‘short’ and ‘long’. Both disorder and globular prediction were taken into account for a more suitable bioinformatical approach. SIM candidates located in unstructured regions — or at least outside globular regions — are considered as more likely to be functional.

4.2. Generation of multiple sequence alignments

4.2.1. Two phylogenetic ranges of species for the identification of orthologs

Orthology inference of *Saccharomyces cerevisiae* proteins was performed with the ‘Inparanoid’ approach [Remm et al., 2001, O’Brien et al., 2005, Berglund et al., 2008, Ostlund et al., 2010]. It allows the identification of one-to-one and one-to-many orthology and can also deal with many-to-many situations by including inparalogs into the cluster sets. The Inparanoid program was applied to all 5885 *Saccharomyces cerevisiae* protein sequences in the genome-wide collection. In order to address SIM candidates which are conserved over different evolutionary distances, two phylogenetic ranges were defined starting from *Saccharomyces cerevisiae*: A set of 12 species comprising the ‘Saccharomycetales’ orthologous sequences and a ‘Saccharomycetaceae’ set of additional 12 species (table 4.5). All *Saccharomyces cerevisiae* protein sequences were aligned with their orthologs to construct the two MSA sets. The performances of different MSA generation tools were tested.

Table 4.5. Two sets of MSA for a characterisation of SIM conservation.

‘Saccharomycetaceae’	
‘Saccharomycetales’	
<i>Saccharomyces cerevisiae</i>	<i>Tetrapisispora phaffii</i>
<i>Saccharomyces bayanus</i>	<i>Torulaspota delbrueckii</i>
<i>Saccharomyces mikatae</i>	<i>Kluyveromyces africanus</i>
<i>Saccharomyces castellii</i>	<i>Saccharomyces arboricola</i>
<i>Vanderwaltozyma polyspora</i>	<i>Eremothecium cymbalariae</i>
<i>Candida glabrata</i>	<i>Naumovozya dairenensis</i>
<i>Zygosaccharomyces rouxii</i>	<i>Debaryomyces hansenii</i>
<i>Saccharomyces kluyveri</i>	<i>Pichia guilliermondii</i>
<i>Kluyveromyces thermotolerans</i>	<i>Candida lusitaniae</i>
<i>Kluyveromyces waltii</i>	<i>Candida albicans</i>
<i>Kluyveromyces lactis</i>	<i>Candida dubliniensis</i>
<i>Ashbya gossypii</i>	<i>Lodderomyces elongisporus</i>

4.2.2. Choice of a suitable multiple sequence alignment tool

For assessing the conservation of SIM candidates, a proteome-wide set of aligned orthologs is required. Since SIMs typically reside within unstructured and poorly conserved sequence regions, the task of generating a meaningful multiple alignment is not trivial.

A number of different multiple alignment programmes are available and were tested for their ability to correctly align established SIM instances. ProbCons, Dialign-TX, MAFFT L-INS-I and MUSCLE were used (section 3.1.2) [Edgar, 2004b, Edgar, 2004c, Katoh et al., 2002, Subramanian and Kaufmann, 2008, Do et al., 2005]. ProbCons and MAFFT performed best, followed by MUSCLE and DIALIGN-TX. However, construction time increased in the order MUSCLE < MAFFT < DIALIGN-TX \approx ProbCons. MAFFT L-INS-I gives the most accurate local alignments on SUMO interacting motifs among the test set alignment methods.

4.3. Conservation criteria from multiple sequence alignments

4.3.1. A suitable metric for assessing residue conservation

MSAs can be used to measure sequence conservation. Two approaches were used to read-out that MSA conservation content:

The substitution matrix approach. Substitution matrices give a mathematical background for the evaluation of conservation within alignment columns (sections 3.1.2.1, 3.1.3). Alignment algorithms use these matrices for the maximization of sequence similarity. In this study, BLOSUM45 and BLOSUM62 matrices are used for the assessment of sequence conservation from MSA data (section 3.1.2.1).

The information theoretical SeqLogo approach. The second approach is based on information theory and thus disregards similarity between the different amino acids (section 3.1.3.2) [Shannon, 1948, Schneider et al., 1986, Schneider and Stephens, 1990]. The information content of an alignment column is used as a conservation measure. This conservation metric is identical to that used by the popular SeqLogo approach for generating graphical alignment representations [Crooks et al., 2004].

There are two ways to describe conservation levels within aligned columns: An ‘all-against-all scoring approach’ (‘N:N’) treats all observed amino acids equally, whereas the ‘one-against-all scoring approach’ (‘1:N’) sets the *Saccharomyces cerevisiae* amino

4. Results

acid as a reference. The 1:N scoring method measures the local similarity of the *Saccharomyces cerevisiae* sequence to all other sequences of the alignment, while the N:N scoring measures the overall conservation within an alignment column.

MSA data generated by MAFFT L-INS-I were used as a basis for bioinformatical procedures. Substitution and SeqLogo approach were used for 1:N and N:N conservation assessments.

In a first step, conservation assessment was performed for the established SIMs in Slx5 and Siz1 in a preliminary test (sections 3.1.2.1, 3.1.3.2 and table 4.6). High scores indicate high information content or high inter-residue similarity, respectively. The overall scores for SIMa in Slx5 and Siz1 are higher than for their flanking regions (not shown).

Table 4.6. The level of SIMa conservation can be calculated with substitution matrix and SeqLogo approaches. Conservation levels are derived from Saccharomycetales MSA. Both ‘one-against-all’ (1:N) and ‘all-against-all’ (N:N) approaches were performed.

Protein	SIMa	BLOSUM45		BLOSUM62		SeqLogo	
		1:N	N:N	1:N	N:N	1:N	N:N
Slx5	V	43	168	35	134	1.558	2.492
	I	68	490	55	401	3.516	3.750
	L	16	-12	6	-57	0.989	2.260
	I	67	475	554	386	3.516	3.750
	D	45	304	41	278	1.085	2.894
	S	53	370	53	371	3.516	3.750
Siz1	I	52	417	47	366	1.340	3.351
	I	70	525	56	420	4.322	4.322
	N	14	235	13	213	0.386	2.896
	L	70	525	56	420	4.322	4.322
	D	93	665	80	574	3.704	3.969
	S	56	420	56	420	4.322	4.322

For a better comparison of conservation features of different established SIMs, another preliminary test was performed. The aim was to decide, whether the substitution or the SeqLogo approach is suited best to assess the conservation criteria. These criteria are to be used for a refined bioinformatical sequence screen.

The conservation scores from ‘Saccharomycetales’ MSA data for Siz1 were compared to the Siz1 domain architecture. The domain architecture of Siz1 (YDR409W) with its established SIMa was retrieved from the Pfam database [Sonnhammer et al., 1997,

4. Results

Bateman et al., 2000, Finn et al., 2010, Finn et al., 2014]: Siz1 has an SAP domain (34–68) in close proximity to the N-terminus, followed by a PINIT domain (170–312), a MIZ zinc finger (357–406) and a SIMa (IINLDS, 482–488) [Johnson and Gupta, 2001, Pichler et al., 2002, Shuai and Liu, 2005, Reindle et al., 2006, Takahashi and Kikuchi, 2005, Uzunova et al., 2007, Yunus and Lima, 2009]. This three-dimensional domain architecture can be directly mapped to the MSA (figure 4.1).

Figure 4.1. Siz1: MSA is a representation of the three-dimensional domain architecture of a protein. MAFFT L-INS-I MSA of *Saccharomyces cerevisiae* Siz1 with homologs within close phylogenetic range, here termed the ‘Saccharomycetales’. Siz1 has an SAP domain (34–68) in close proximity to the N-terminus, followed by a PINIT domain (170–312), a MIZ zinc finger (357–406) and a SIMa (IINLDS, 482–488) [Johnson and Gupta, 2001, Pichler et al., 2002, Shuai and Liu, 2005, Reindle et al., 2006, Takahashi and Kikuchi, 2005, Uzunova et al., 2007, Yunus and Lima, 2009]. Violet boxes indicate conserved domains, whereas the orange box indicates the SIMa.

As shown in figure 4.1, globular protein domains and motifs usually correspond to regions with high sequence conservation. Furthermore, information theoretical approaches can mathematically address alignment files for conservation assessments (sections 3.1.2.1, 3.1.3.2, table 4.6). GnuPlot plots of the conservation scores against the *Saccharomyces*

4. Results

cerevisiae protein sequence coordinates serve as a graphical representation for protein conservation (figure 4.2). The information theoretical SeqLogo approach gives scores in a narrow range between 0 and ~ 4.22 (section 3.1.3.2).

Figure 4.2. Gnuplot graphical representation of conservation scores from SIZ1 ‘Saccharomycetales’ MSA. The calculated conservation values are plotted against the *Saccharomyces cerevisiae* sequence coordinates. The scores are calculated with the substitution matrix approach (a,d: BLOSUM45; b,e: BLOSUM62) and with the information theoretical SeqLogo approach (c,f). **Violet** boxes indicate conserved domains as of a SAP domain (34–68), a PINIT domain (170–312) and a MIZ zinc finger (357–406). **Orange** box and arrow indicate the SIMa (482–488). It is shown highly conserved, whereas the level of background conservation is not.

4.3.2. Smoothing of information raw data as conservation measures

The overall conservation score of the SIM should be higher than it is for their flanking regions. The terms ‘absolute conservation’ and ‘relative conservation’ are measured with a sliding average technique on conservation scores. A sliding window with the same size as the motif returns the ‘absolute conservation’ of the motif (w_1), whereas a sliding window of much larger size gives the ‘background conservation’ (w_2). The difference between these sliding average values determines the ‘relative’ conservation (section 3.1.3.3):

4. Results

$w1$: Absolute conservation of a putative motif.

$w1 - w2$: Relative conservation of a putative motif over its flanking regions.

$w2$: Background conservation of the putative motif.

Different sets of sliding average window sizes have been tested for characterisation and detection of established SIMa within the genome-wide protein sequence collection: Window sizes between 5 and 11 for absolute conservation were combined in a permutative way with sliding window sizes 25, 35, 51, 67 and 99 for the level of background conservation (table 4.7). These pairs of different window sizes define sets of three thresholds ($t1$, $t2$ and $t3$) for minimum absolute conservation, maximum background conservation and minimum relative conservation. These mathematical thresholds are specific for each $[w1, w2]$ pair and are defined as $w1(x)$ and $w2(x)$ with x the sequence position:

$$t1 < w1(x) \quad t2 > w2(x) \quad t3 < (w1(x) - w2(x))$$

The large window ($w2$) is carefully chosen to include enough values to determine the motif's background conservation. Conserved flanking regions get a larger impact on the background conservation with larger sliding average windows.

The 1:N SeqLogo information theoretical approach was used for the final prediction procedure. The thresholds $t1$, $t2$ and $t3$ allow to scan a genome-wide protein sequence collection for putatively functional SIM candidates.

Figure 4.3. Conservation thresholds $t1$, $t2$ and $t3$ allow to describe an established SIMa. Gnuplot graphical representation of Siz1 conservation scores with employed sliding average technique. Conservation scores were calculated from ‘Saccharomycetales’ MSA with the information theoretical SeqLogo approach (green). Two different sliding averages $w1=7$ (red) and $w2=51$ (black) were applied. The difference between the plots $w1$ and $w2$ accounts for the relative sequence conservation. Plots for $w1$ and $w2$ show the absolute and background conservation, respectively. Violet boxes indicate conserved domains as of a SAP domain (34–68), a PINIT domain (170–312) and a MIZ zinc finger (357–406). Orange box and arrow indicate the SIMa (482–488). It is shown with high absolute (red) and moderate background conservation (black).

4. Results

Table 4.7. The sliding average technique with different window sizes (w_1, w_2) determines a distinct conservation threshold triplet (t_1, t_2, t_3) for established SIMa. Absolute conservation refers to t_1 as a minimum information given by sliding average w_1 , whereas the background conservation is described by sliding average w_2 . Threshold t_2 gives a maximum background limitation. The relative conservation of the motif is determined by the difference $w_1 - w_2$ of these sliding averages. Threshold t_3 gives a minimum amount for that.

protein	parameter	w1=5									w1=7									w1=9

4.4. The bioinformatical SIM detection approach

The three SIM types have different requirements for a bioinformatical SIM detection procedure. The bioinformatical procedures are performed for each SIM type independently, whereas the basic assumptions for the approaches are the same.

4.4.1. Basic steps of the bioinformatical approach

The bioinformatical approach for a SIM detection within databases comprises the following steps:

- Established SIMs are used for SIM consensus profile construction.
- Conservation data is directly calculated from ‘Saccharomycetales’ and ‘Saccharomycetaceae’ MSA. Suitable thresholds (t_1 , t_2 and t_3) for the individual SIM types were chosen so that established SIMs pass them while spurious sequences do not.
- The structural contexts of established SIMs are tested with different bioinformatical tools. Such a bioinformatical tool is defined suitable when it predicts an established SIM in a non-disordered protein region.

The results from profile and consensus pattern searches are combined with conservation data and data for the structural context. The overall score is trained on established motifs. A scoring method gives lists of SIMs, in which functional motifs are enriched. The selection of SIM candidates for experimental validation is based on these overall scores together with the believed biological relevance for the respective motif.

4.4.2. SIMa

4.4.2.1. Consensus pattern and profile from established SIMa for a bioinformatical SIMa screen

Conservation criteria were optimized on established SIMa sequences in Fir1, Slx5, Slx8, Uls1, Siz1, Uba2 and Wss1 in the last section. These SIM sequences are used to derive both a SIM consensus pattern and a consensus profile from their ‘Saccharomycetales’ MSA was derived (figure 4.4).

For the SIMa consensus pattern, isoleucine, leucine, methionine and valine were accepted for the hydrophobic portion, while aspartate, glutamate and serine were accepted for the acid stretch. Searching a *Saccharomyces cerevisiae* protein sequence collection with a

4. Results

Figure 4.4. Schematic derivation of a consensus pattern (left) and a sequence profile (right) from established SIMa.

SIMa consensus pattern $[ILVM][ILVM].[ILVM][SDE][SDE]$ returned 1955 consensus-like short sequence strings in 1264 different protein sequences, among them all established SIMa instances. (table 4.2). A preliminary profile screen of a corresponding SIMa sequence profile against a sequence collection of established SIPs gave a maximum sensitivity of $C = 4.0$ to return the established SIMs from a genome-wide sequence collection (table 4.8). Results from both the consensus pattern and the consensus profile search were taken as queries for conservation and disorder prediction data collections.

Table 4.8. Profile scores from a SIMa profile-based protein database screen returns established SIMa.

Slx8	VLQISDDD	4.481
Nis1	IIIPDSQD	3.815

4. Results

4.4.2.2. Conservation scores to discriminate between SIM-like sequences

The thresholds determine the borderline SeqLogo scores for a conservation threshold-based SIMa screen. Conservation thresholds were selected as $t1 = 1.16$, $t2 = 1.08$, $t3 = 0.37$ for ‘Saccharomycetales’ MSA. These thresholds were applied in the bioinformatical approach. Most established SIMs meet this conservation conditions and can be therefore selected from random motifs (table 4.7). Thresholds for Saccharomycetaceae MSA were not selected as an exclusive measure. Scores for absolute, relative and background conservation from the ‘Saccharomycetaceae’ MSA served as an additional measure for the quality of a putative SIM instance. Profile-based sequence scans for established and unknown SIMs were combined with a conservation threshold approach. This approach combines cut-off sensitivity from the profile-based screen and conservation thresholds. It is therefore more restrictive than the single approaches. After preliminary tests with different profile scan sensitivities and two sets of conservation thresholds, the effects of pattern-based, profile-based and conservation threshold-based search methods were investigated (table 4.9). For the final SIMa detection approach, a sensitivity of $C = 3.2$ was used for the profile-based screen in combination with a relaxed set of conservation thresholds $t1 = 1.0$, $t2 = 1.6$, $t3 = 0.2$.

Table 4.9. Effects of different combinations of sequence and conservation restrictions on the results of a genome-wide sequence search. Consensus pattern-based and profile-based search methods with and without use of conservation thresholds in a *Saccharomyces cerevisiae* protein sequence collection. [ILVM] [ILVM] . [ILVM] [SDE] [SDE] was used as a SIMa pattern.

4. Results

4.4.2.3. GlobPlot and IUPred disorder/globularity prediction

Disorder and globularity prediction assessments were performed for all *Saccharomyces cerevisiae* protein sequences. The use of a sliding average window was helpful using a small window size of 7 residues to gain the local disorder and globularity, respectively, of a putative motif. A sliding average of 51 residues was used to additionally indicate whether a putative SIM could lie in a disordered region and as an indicator for its distance to that disordered region. The sliding average approach is analogous to the method used to assess local conservation. A ‘disorder score’ was introduced as a mathematical combination of disorder assessments and their sliding averages. The results showed that established SIMs — except for Wss1 — were predicted as non-globular by both globularity predictors, GlobPlot and IUPred. The disorder prediction performed well.

4.4.2.4. Combination of sequence consensus, conservation thresholds and disorder/globularity prediction data

The previous paragraphs demonstrate that it is possible to define thresholds for consensus adherence, absolute and relative conservation, and disorder prediction, which are passed by most established SIMs but not by random sequences. Based on this finding, a universal screen for new SUMO interacting proteins was devised, which encompasses the following steps:

- 1) A profile scan with a reduced sensitivity of $C = 3.2$ as cut-off value was started. This cut-off value allows significant reduction of putative sequence positions (table 4.9). The returned profile scores were taken as a similarity measure to a SIMa consensus pattern.
- 2) Permissive thresholds for absolute, relative and background conservation were established both to a narrow (‘Saccharomycetales’) and wider phylogenetic range (‘Saccharomycetaceae’) (table 4.9). A scoring technique for the returned sequence positions was also applied to the obtained conservation scores w_1 , w_2 , w_3 to result in a combined conservation score.
- 3) Disorder and globularity assignment data from GlobPlot and IUPred were combined with the results from the profile-based database screen.

Inclusion of disorder assessments into the SIM detection approach was even more restrictive. Therefore, conservation thresholds were reduced from $[t_1 = 1.16, t_2 = 1.08, t_3 = 0.37]$ to $[t_1 = 1.0, t_2 = 1.6, t_3 = 0.2]$ to give more motif hits. This hit number

4. Results

was further reduced by applying disorder assessment data. The final list contains all motif candidates that fulfill the thresholds for consensus similarity, conservation and disorder (tables 4.10, 4.11). The candidates are ranked by a combined score. Different predictions are shown for the narrow and wider set of MSAs, which differ mainly in their conservation scores.

The top part of the table shows the results of the scoring system applied to established SIMs (Fir1, Uls1, Slx5, Slx8, Siz1). They are predicted by GlobPlot and IUPred as expected: as non-globular and disordered. The combination with profile scores and conservation characteristics serves as a quantification method for a SIM candidate to be relevant. The results of so far unpublished SIMa-like sequences are given in the bottom part of the tables. Those putative motifs are collected by their high overall scores for different reasons:

Rad5 and Rfc1 are overall scored similar to established SIMs like the one in Fir1. Rrb1 shows too high background conservation for the given thresholds, but still good values for profile score, conservation characteristics and disorder assignments. Putative motifs in Dbp10 and Drs1 fail in the profile score cut-off values. The other values are still promising. Rad5 and Rfc1 are involved in the PCNA pathway, which is known to be regulated by SUMOylation [Torres-Ramos et al., 2002, Beckwith et al., 1998, Höge, 2002]. A SUMO interacting motif in Rad5 and Rfc1 may be biologically plausible. Rrb1, Dbp10 and Drs1 are involved in ribosomal biogenesis. SIMs in proteins with this biological background have not been reported yet. Further investigations on these proteins are carried out in this study and are described in later sections in this thesis.

4. Results

Table 4.10. Final results from a genome-wide bioinformatical SIMa screen (part I). The results are compared to established SIMa in Fir1, Uls1, Slx5, Slx8 and Uls1. A profile scan with sensitivity $C = 3.2$ was run on a *Saccharomyces cerevisiae* protein sequence collection and the results were combined with conservation characteristics $t1 = 1.0$, $t2 = 1.6$, $t3 = 0.2$ and GlobPlot globularity/disorder assignments. Additional information on these established and putative SIMs are collected below (table 4.11).

4.4.3. SIMb

4.4.3.1. Consensus pattern and profile from established motifs for a bioinformatical SIMb screen

The SIMb consensus pattern in SeqLogo representation (table 1.2) shows a well defined consensus pattern VIDLT. Alignment data of *Saccharomyces cerevisiae* Wss1 and Uls1 support such a profile close to that consensus pattern. An ‘Saccharomycetales’ MSA of Uls1 (figure 4.5) shows a conserved array of low variant alignment columns. They form the conserved SIMb in the amino terminus region of the MSA.

Figure 4.5. SIMs are highly conserved and lie in more variant MSA regions. Extract from a multiple sequence alignment of *Saccharomyces cerevisiae* Uls1 (YOR191W) and orthologous sequences. The Uls1 SIMb near the protein’s amino terminus outshines an area of low residue variation by its high conservation, highlighted by the graphic tool “belvu”.

A preliminary SIMb profile and consensus pattern scan in the genome-wide *Saccharomyces cerevisiae* protein sequence collection with and without conservation thresholds $t1$, $t2$, $t3$ was run to fine-tune scan sensitivity and thresholds to use (tables 4.13, 4.12). These tests were set up in the same way as for the SIMa threshold determination. SIMb conservation characteristics are again presented by sliding window averages $w1 = 7$ and $w2 = 51$. Thresholds for this small test set were determined as $t1 = 1.75$, $t2 = 1.55$ and $t3 = 1.0$ (table 4.12). With these values, sequence collection scans with thresholds only or with additional use of either consensus pattern [PTVILM] [ILMV] DLT or a SIMb profile were performed (table 4.13). The results were combined with globularity and disorder assignments (table 4.14, 4.15).

4. Results

Table 4.12. The sliding average technique with different window sizes (w_1, w_2) determines a distinct conservation threshold triplet (t_1, t_2, t_3) for SIMb. Different sliding average window sizes for a shorter consensus sequences for SIMb compared to SIMa were tested on established SIMb in Uls1 and Wss1. Conservation data is based on ‘Saccharomyces cerevisiae’ MSA. Different combinations of sliding averages of 3, 5 and 7 residues and sliding averages for background conservation of 25, 35, 51, 67 and 99 residues were investigated. Conservation characteristics were recorded as thresholds with respect to the given SIMb. A set of overall thresholds was finally derived as $t_1 = 1.75$, $t_2 = 1.55$, $t_3 = 1.0$.

Table 4.13. Comparison of results from SIMb pattern and profile scans in a *Saccharomyces cerevisiae* protein sequence collection. Several profile scan sensitivity cut-off values ($C = 3.0, C = 3.2$ and $C = 4.0$) were applied. The results are compared with a SIMb consensus pattern search ([PTVILM][ILMV]DLT) with and without conservation thresholds applied ($t_1 = 1.75, t_2 = 1.55$ and $t_3 = 1.0$). The 7 different protein sequences after pattern scan are those of Ctf3, Dxo1, Psd1, Sap1, Ulp1, Uls1 and Wss1.

scan type	t_1	t_2	t_3	matching sequence positions	different protein sequences
-	-	-	-	2,915,898	5,885
	1.75	1.55	1.0	39,629	2,962

	1.75	1.55	1.0	429	124
profile ($C = 4.0$)	-	-	-	3,735	349
	1.75	1.55	1.0	138	32

4.4.3.2. Combination of sequence consensus, conservation thresholds and disorder/globularity prediction data

The combination of conservation scores and disorder/globularity assessments to a ranking of putative SIMb candidates in *Saccharomyces cerevisiae* was applied to data for Wss1, Uls1 and Siz1. Additionally, a profile sensitivity of $C = 4.0$ was used for the *Saccharomyces cerevisiae* protein sequence collection scan. The filtering of the obtained motif matches by using the conservation thresholds ($t = 1.75$, $t_2 = 1.55$ and $t_3 = 1.0$) reduced the number of SIMb candidates to 32. Evaluation of these findings led to a selection of proteins for further investigations (tables 4.14, 4.15): As expected, the established SIMb of Uls1 and Wss1 were found in the screen with high profile scores. They show good absolute and relative conservation. However, GlobPlot gives no disorder or globularity propensities for the given SIMb. IUPred gives low propensities for disorder, but higher ones for globularity. A comparison with other putative SIMb from the collection gave mixed findings for both established SIMb and chosen candidates from a final selection:

Putative motifs in Rfc1, Sap1, Sec27, Slx4 and Tdp1 show similar tendencies in conservation characteristics as Wss1 and Uls1 SIMb. Motifs in Rfc1, Sap1 and Sec27 are similarly close to the SIMb consensus as are Wss1 and Uls1. They are predicted by IUPred to reside in putatively more likely disordered regions. Less confident disorder predictions were obtained for Slx4, Tdp1 and Top1. The Top1 motif shows poor relative conservation.

Rfc1 was already detected in a SIMa screen. Whereas Rfc1 could follow an intermediate consensus pattern, a SIMb-like sequence in Sec27 (LIDL) appears atypical. Functionality of Sec27 SIMb was not expected, but tested along with the other chosen candidates from the final selection.

4. Results

Table 4.14. Final results from a genome-wide bioinformatical SIMb screen (part I). The results are compared to established SIMb in Uls1 and Wss1. A profile-based scan with sensitivity $C = 4.0$ was performed in a *Saccharomyces cerevisiae* protein sequence collection. The results were combined with conservation thresholds $t1 = 1.75$, $t2 = 1.55$, $t3 = 1.0$ and GlobPlot globularity/disorder assignments. Additional information on these established and putative SIMs are collected in table 4.15 below.

4. Results

4.4.4. SIMr

4.4.4.1. Consensus pattern from established SIMr for a bioinformatical SIMr screen

At the beginning of this study, only few SIMr data were known, including a “reverse SIMa” DDVLIV in human protein RanBP2 and two putative SIMr in *Saccharomyces cerevisiae* Elg1 [Song et al., 2004, Parnas et al., 2010]. During this study, a SIMr in Rad18 was published [Parker and Ulrich, 2012]. A *Saccharomyces cerevisiae* protein sequence collection scan was run with a reverse SIMa consensus pattern [SDE] [SDE] [ILVM] . [ILVM] [ILVM]. The results were combined with conservation thresholds from the previous SIMa and SIMb detection scans with and without employing a threshold (table 4.16). SIMa and SIMr consensus patterns show similar effects on a pattern search in a protein sequence collection. The restrictive SIMa thresholds $t1 = 1.16$, $t2 = 1.08$, $t3 = 0.37$ appeared to be too stringent for a SIMr screen with respect to a final collection of putative SUMO interacting proteins. Therefore, the most restrictive thresholds were applied and the results checked manually for biological relevance with SUMO interaction.

Table 4.16. Genome-wide pattern-based sequence scan using three sets of conservation thresholds in synergy with SIM consensus patterns and profiles. *Saccharomyces cerevisiae* protein sequence collection scan was performed with a SIMr consensus pattern [SDE] [SDE] [ILVM] . [ILVM] [ILVM]. The findings are combined with conservation thresholds from both SIMa and SIMb screens.

consensus pattern	$t1$	$t2$	$t3$	matching sequence positions	number of different protein sequences

	1.16	1.08	0.37	200	56
	1.0	1.6	0.2	744	196

4. Results

The SIMr consensus pattern-based screen with [SDE] [SDE] [ILVM] . [ILVM] [ILVM] returns 51 putative SIM sequences within the *Saccharomyces cerevisiae* protein sequence database. Conservation thresholds $t1 = 1.75$, $t2 = 1.55$ and $t3 = 1.0$ were applied. Evaluation of these findings was performed analogous to the previous SIMa and SIMb screens. No profile scoring technique was used, as a suitable SIMr profile needed more data. The ranking of the SIMr pattern search was only conducted from conservation and disorder/globular assignment scores (tables 4.17, 4.18).

Selected for further investigations were a putative SIMr and a SIMa in Ulp2, which can be interpreted as SIMr with preceding serine residues, and a SIMr in Rad18 with its biological context of being involved in SUMO-dependent PCNA regulation. Conservation characteristics, disorder and globular assignments support this selection: Uls1 shows less local conservation ('raw' and 'w1') than the other candidates in the list, whereas its relative conservation ('w1-w2') is comparable. None of the candidates is predicted as being globular. Whereas one putative motif in Ulp2 (no. 2) and the one in Rad18 have less GlobPlot disorder scores, IUPred disorder works better for Ulp2 (no. 2).

4. Results

4. Results

4.4.5. Selection of possible SUMO interacting proteins for validation

The following putative SUMO interacting motifs in *Saccharomyces cerevisiae* were selected from the final selection lists to show that the approach outlined above is able to enrich SIMs from a collection of protein sequences (table 4.19).

The selection is based on data from profile-based scans for new SIMs in a *Saccharomyces cerevisiae* protein sequence collection. The results were then combined with conservation data from ‘Saccharomycetales’ MSA and disorder/globular assignment data from GlobPlot and IUPred. Visual inspection of the final results was performed to further narrow the number of putative interacting motifs.

Rad5 is a known DNA helicase and ubiquitin ligase [Torres-Ramos et al., 2002, Parker and Ulrich, 2009, Carlile et al., 2009, Halas et al., 2011]. The proteins Rfc1 and Rad18 are known to be involved in the regulation of the SUMOylated protein PCNA [Bailly et al., 1997, Beckwith et al., 1998, Parker and Ulrich, 2012]. A SUMO interacting motif in those proteins is therefore biologically plausible. The putative SIM in Rad5 would be a SIMa type, in Rfc1 a SIMa/b intermediate and in Rad18 a SIMr type. Their high profile scores show a close sequence similarity to established SIMs. Combined with high values for absolute and relative conservation, these putative SIMs from the bioinformatical screen offer the possibility to investigate its performance on enriching a protein sequence collection. A putative motif sequence LIDL in Sec27 would be similar to a SIMb consensus, but with a glutamate instead of a threonine. The sequence can be described as intermediate between the Uls1 SIMb TIDL and a putative Rfc1 motif VIDLDT. Another group of SIM candidates in the proteins Rrb1, Dbp10 and Drs1 was selected due to their involvement in ribosomal biogenesis. So far, a regulation of this process by SUMO has not been described. Despite higher background (Rrb1) and low consensus pattern similarity (Dbp10, Drs1), SIM validation would open a new field of research for SUMO. In a second phase of this study, additional SIM candidates with lower relative conservation but a high profile score combined with low (Top1), or high (Slx4) absolute conservation were selected. Tdp1 shows good absolute conservation. Slx4 is predicted globular by both IUPred and GlobPlot. A SIM in Slx4 is not expected.

4. Results

Table 4.19. Final selection of putative motifs for experimental validation from the bioinformatical genome-wide SIM screens. The final selection lists are set up for enrichment of SUMO interacting motifs. Further validation experiments on these proteins was performed.

SIM type	protein	sequence motif	comment
SIMa	Rad5	IIDL DN	-
	Rrb1	IIEI DG	higher background conservation
	Dbp10	VIEY SS	low profile score
	Drs1	VPIL DS	low profile score
	Rfc1	VIDL DT	-
SIMb	(Rfc1)	(VIDL DT)	-
	Sap1	LIDLT	-
	Sec27	LIDL	putatively new consensus pattern
	Slx4	IIDL	globular by GlobPlot
	Tdp1	IIDL	low absolute conservation
	Top1	EIDL	low relative conservation
SIMr	Rad18	(DD LQIV)	validated, [Parker and Ulrich, 2012]

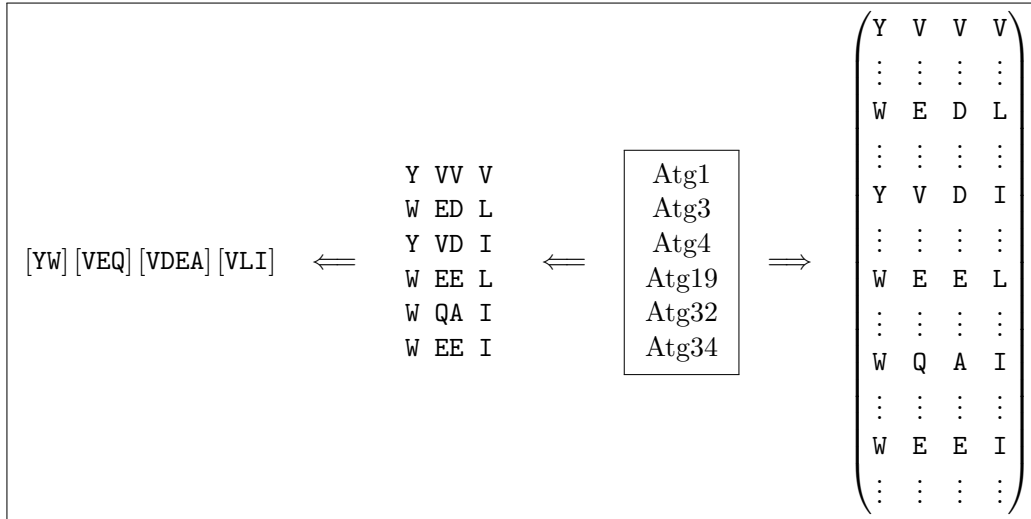

4.5. Application of analogous methods for a genome-wide AIM screen in *Saccharomyces cerevisiae*

The characterized AIMs of the budding yeast autophagy regulators Atg1, Atg3, Atg4, Atg19, Atg32 and Atg34 and their homologs from other yeast species were used to derive an AIM-specific consensus pattern and sequence profile (table 1.4, figure 4.6). The consensus pattern has a low information content due to its short sequence and lack of additional sequences. An AIM consensus pattern is composed of a segment of four residues with sequence constraints at positions one and four. This stretch is usually preceded by acidic residues, neglected in figure 4.6. The two middle positions give a broad variation within the MSA. Therefore, these positions were left open completely in a putative consensus pattern [WYF]..[ILV].

AIM are short linear motifs which adopt a β -strand structure upon binding to Atg8. But they are located in an otherwise more variant protein region. These features are also common with SIM. Therefore, the SIM prediction procedure may be adapted to an AIM prediction method, as well. Conservation data from ‘Saccharomycetales’ MSA were derived either by the substitution matrix approach or the information theoretical SeqLogo approach for established AIM (table 4.20). The information theoretical SeqLogo scores show the expected similarities to the SIM information scores: Conservation scores

4. Results

Figure 4.6. Schematic derivation of a consensus pattern (left) and a sequence profile (right) from established AIM. The profile is represented as composed of a stack of single AIM. The pattern can be described as the overall composition of several sequences at once, whereas a profile is derived from aligned AIM instances and therefore has a much higher information content than its respective sequence pattern.

based on BLOSUM matrices are less suited for the detection of conserved motifs on a non-motif background than the information-theoretical scores of the SeqLogo approach. The SeqLogo scoring technique serves as descriptor of the information content of each AIM position within the ‘Saccharomycetales’ MSA.

First, a test for a set of conservation thresholds t_1 , t_2 , t_3 most suitable for AIM detection was performed; the procedure was analogous to that employed for SIM binding as described above. Different permutative combinations of window sizes 3, 5 and 7 (w_1) with 25, 35, 51, 67 and 99 (w_2) were investigated (table 4.21): Window sizes 3 and 5 resulted in higher information contents and in higher absolute conservation values t_1 than for a window of 7 residues. The differences between a 3- and a 5-residue window were marginal. Larger window sizes for background conservations returned larger information levels with increasing window size. However, the interplay of small and large window sizes for absolute, background and relative conservation limited the choice of suitable sliding average windows and conservation thresholds. Thresholds t_1 , t_2 , t_3 for AIM detection were set for window sizes $w_1 = 5$ and $w_2 = 35$.

4. Results

Table 4.20. The level of AIM conservation can be calculated the same way as for SIMs using substitution matrix and information theoretical approaches. ‘One-against-all’ (1:N) and ‘all-against-all’ (N:N) approaches were applied with these methods.

Protein	AIM	BLOSUM45		BLOSUM62		SeqLogo

The AIM in Atg19 is less well conserved than the other training AIMs, and require the use of rather permissive threshold values. Atg1 showed high values for both absolute and background conservation. High background conservation values affected the derivation of thresholds for less constraint values and therefore for more putative hits from a screen. Three different sets of conservation thresholds can be considered, depending on a tradeoff between sensitivity and selectivity (tables 4.22, 4.23). The established AIM in Atg1 has a low profile score of 1.552 due to its atypical AIM sequence YVVV. In its ‘Saccharomycetales’ MSA, this motif is at the C-terminal end of a highly conserved region.

4. Results

Table 4.21. The sliding average technique with different window sizes ($w1$, $w2$) determines a distinct conservation threshold triplet ($t1$, $t2$, $t3$) for AIM. Sliding average window sizes of 3, 5 and 7 were combined with sliding averages for background conservation of 25, 35, 51, 67 and 99 residues. Conservation characteristics were recorded as thresholds with respect to the given AIM. A combination of sliding averages of 5 and 35 alignment positions was found useful. Two sets of overall thresholds were finally set as $t1 = 1.42$, $t2 = 2.12$, $t3 = 0.6$ (neglecting the Atg1 and Atg19 AIM) and $t1 = 1.42$, $t2 = 2.62$, $t3 = 0.6$ (only neglecting Atg19 AIM).

4. Results

Table 4.22. Derivation of conservation thresholds for AIM detection. Three sets of thresholds t_1 , t_2 , t_3 could be determined from combinations of different sliding average windows. The test set comprised established AIM in Atg1, Atg3, Atg4, Atg19, Atg32 and Atg34 in *Saccharomyces cerevisiae*. With final sliding windows of 5 and 35 positions, the sets vary depending on the different conservation characteristics of the AIM included. Whereas the first row comprises the data from all AIM mentioned, the second and third lack Atg19 AIM and the AIM of Atg19 and Atg1, respectively.

included established AIM		t_1	t_2	t_3
Atg1	, Atg3, Atg4, Atg19, Atg32, Atg34	1.29	2.62	0.6
	Atg1, Atg3, Atg4, Atg32, Atg34	1.41	2.62	0.6
	Atg3, Atg4, Atg32, Atg34	1.42	2.12	0.6

Table 4.23. Profile scores of established AIM. A profile was derived from established AIM in Atg1, Atg3, Atg4, Atg19, Atg32 and Atg34. A profile-based scan within a *Saccharomyces cerevisiae* protein sequence collection gave the presented profile scores.

Protein	AIM	profile score
Atg1	EYVVV	1.552
Atg3	DWEDL	5.521
Atg4	DYVID	3.980
Atg19	TWEEL	3.420
Atg32	SWQAI	2.953
Atg34	TWEEI	3.747

This region is large enough to give good absolute conservation scores for the AIM, but short enough to show good relative conservation with larger sliding windows w_2 . According to these scores, the adapted approach may be suitable for the detection of AIMs. The high level of background conservation interferes with the characteristics of the other AIM in terms of conservation and consensus pattern adherence. Therefore, the AIM in Atg1 is not considered any further to improve the conditions for parameter adjustment to the other established AIM (table 4.24). The used AIM profile was modified according to that. Improvements on profile scores compared to the previous profile screen (table 4.23) can be observed with the altered AIM profile (table 4.24). With these newly constructed profiles the genome-wide *Saccharomyces cerevisiae* protein sequence collection was searched for AIM consensus-like sequences (table 4.25) with the pattern [WYF]..[ILV] with and without application of conservation thresholds (table 4.25). For an AIM detection approach similar for the ones established with SIMs in this study, a profile scan was performed with a cut-off value of $C = 3.0$, which leaves the established AIM of Atg3, Atg4, Atg19, Atg32 and Atg34 within the collection of 1,312 putative AIM proteins (table 4.25). Additional use of conservation thresholds $t = 1.42$, $t_2 = 2.62$ and $t_3 = 0.60$ helped reduce the number of putative AIM candidates (tables 4.26, 4.27).

4. Results

Table 4.24. Profile scores to established AIM. A profile was derived from established AIM in Atg3, Atg4, Atg19, Atg32 and Atg34. Atg1 was omitted. A profile scan within a *Saccharomyces cerevisiae* protein sequence collection gave the here presented profile scores.

Protein	AIM	profile score
Atg3	DWEDL	5.660
Atg4	DYVID	3.340
Atg19	TWEEL	3.862
Atg32	SWQAI	3.103
Atg34	TWEEI	4.102

Table 4.25. AIM consensus pattern search using [WYF]..[ILV] and a profile search based on MSA of established AIM was performed in a *Saccharomyces cerevisiae* protein sequence collection.

4.6. Experimental validation of SUMO interacting motifs in *Saccharomyces cerevisiae*

The bioinformatical screens gave lists of SIM-like short sequences and their corresponding proteins. Among these protein sequences, putatively functional SIMs are believed to be enriched. After performance of bioinformatical prediction procedures for SIMa (section 4.4.2), SIMb (section 4.4.3) and SIMr (section 4.4.4), a selection was made for new putatively functional motifs for experimental interaction studies (tables 4.19, 4.28). Three experiments were performed:

First, truncated protein sequences of Sec27, Rad5, Rrb1, Dbp10, Drs1, Rfc1 and Rad18 from the bioinformatical screens were investigated in yeast two-hybrid experiments. Rfc1 and Rad18 show SUMO interaction. In a second experiment, these proteins were tested as full length-proteins using the GST-SUMO pulldown technique. SUMO interaction of Rfc1 and Rad18 was confirmed. Dbp10 and Drs1 show SUMO interaction, in contrast to negative interaction results from yeast two-hybrid experiments. In an additional yeast two-hybrid experiment, putative SIMs in Slx4, Tdp1 and Top1 from the bioinformatical SIMb detection screen were tested (table 4.28). SIMb instances in these proteins appeared less favourable for SUMO interaction than the instances in the previous experiments. SUMO interaction is shown for Tdp1.

Table 4.28. Selection of putative SIM sequences from the previous bioinformatical screens for experimental validation. SUMO interaction is shown for Rfc1, Rad18 and Tdp1 in yeast two-hybrid experiments. These interactions are further shown in GST-pulldown assays for Rfc1 and Rad18, and additionally for Dbp10 and Drs1. SUMO/SIM interaction for Rfc1 is shown in growth phenotype analysis upon chemically induced DNA replication stress.

4. Results

Rad18 and Rfc1 are involved in DNA binding and DNA damage repair [Bailly et al., 1997, Yao, 2003, Parker et al., 2008, Parker and Ulrich, 2012]. The biological relevance of SUMO/SIM interaction for these proteins was about to be tested in stress tests. However, SUMO interaction for Rad18 was meanwhile shown by Parker and Ulrich [Parker and Ulrich, 2012]. They also show a SIMr instance responsible for the interaction [Parker and Ulrich, 2012]. A SIM mutation in RFC1 was introduced into *Saccharomyces cerevisiae* strain JD47-13C. That *rfc1* SIM defective strain was exposed to thermal and chemical stress. It showed an observable phenotype compared to the wild-type strain.

4.6.1. Verification of SUMO/SIM interaction in Rfc1 using the yeast two-hybrid technique

The core component in this yeast two-hybrid approach is the *Saccharomyces cerevisiae* Gal4 transcriptional factor which regulates Gal4 expression resulting in the activation of a reporter gene (section 3.2.16) [Joung et al., 2000]. This transcriptional factor is composed of two physically separateable, functionally independent domains: Gal4 activating domain (GAD) and Gal4 binding domain (GBD). Cloning of gene fusions to these domains allows validation of interaction between the coding protein sequences. Interaction of the expressed proteins reassembles GAD and GBD to restore Gal4 transcriptor activity for *HIS3* and *ADE2* reporter gene expression.

Truncated protein versions of Sec27, Rad5, Rrb1, Dbp10, Drs1, Rfc1 and Rad18 comprising the respective SIM sequences were used in a first yeast two-hybrid experiment. In a second yeast two-hybrid experiment full-length proteins of Tdp1, Top1 and Slx4 were used. They were cloned and expressed as GAD fusions to their amino termini (table 4.29). The constructed plasmids were isolated and verified by their unique restriction pattern in agarose gel electrophoresis and by Sanger sequencing. GBD was cloned to nucleotide sequences coding for *Saccharomyces cerevisiae* SUMO paralog Smt3 and different Smt3 chain versions. These Δ G97 truncated Smt3 chains were used to investigate whether interaction differences occur with different Smt3 chain lengths. These GBD constructs were expressed as GBD fusions to the amino termini of Smt3. GBD-Smt3, GBD-Smt3 Δ 97, GBD-Smt3 \times 3 and GBD-Smt3 \times 4 fusions from different plasmids were taken from the Dohmen *et al.* lab collection. Expression of these GBD fusion proteins were shown in western blots in previous studies using α -GST-SUMO antibody (table 2.8). Plasmids only expressing GAD and GBD both with and without C-terminal HA tag were used as controls. They are referred to as ‘GAD-C1’ and ‘GBD-C1’ hereafter.

4. Results

Table 4.29. GAD protein fusions with their different insert sizes used in this study. A plasmid expressing only the Gal4 binding domain was used with and without C-terminal HA tag as negative control in the yeast two-hybrid experiments. A C-terminal HA tag was introduced for expression level visualization using western blotting. The top part of the table comprises the GAD fusion proteins for a first yeast two-hybrid approach. After yeast two-hybrid experiments had only shown SUMO interaction for Rfc1 and Rad18, Tdp1, Top1 and Slx4 were investigated.

GAD protein fusion	inserted nucleotide sequence
GAD	-
GAD-HA	-
GAD-Sec27-HA	Sec27, 930-1260
GAD-Rad5-HA	Rad5, 1-1260
GAD-Rrb1-HA	Rrb1, 1-615
GAD-Dbp10-HA	Dbp10, 1-1529
GAD-Drs1-HA	Drs1, 1-1731
GAD-Rfc1-HA	Rfc1, 1-705
GAD-Rad18-HA	Rad18, 1-801
GAD-Tdp1	Tdp1, full length
GAD-Top1	Top1, full length
GAD-Slx4	Slx4, full length

Yeast two-hybrid experiments were performed (section 3.2.16). An HA tag was introduced for expression control in western blots (figure 4.7). The expression levels differ between fusion proteins. GAD-Sec27-HA, GAD-Dbp10-HA and GAD-Rrb1¹⁻⁵⁴⁰-HA are not sufficiently expressed. No SIM interaction results for GAD-Sec27-HA and GAD-Dbp10-HA are presented due to their low expression detected in the western blot analysis. The other proteins are expressed at higher levels.

SUMO interaction was detected as growth on synthetic drop-out (SD) media plates lacking leucine and tryptophan (SD-LW) and additionally either histidine (SD-LWH) or adenine (SD-LWA). 3-amino-1,2,4-*H*-triazole (3-AT) is a competitive inhibitor to *HIS3* [Struhl and Davis, 1980, Brennan and Struhl, 1980, Joung et al., 2000]. Cells need higher expression levels of histidine for survival on SD-LWH selection plates supplemented with 3-AT. Experiments were repeated several times with equal results in both PJ69-4A and AH109 yeast strains (figure 4.8). From these yeast two-hybrid experiments, only GAD-Rfc1-HA and GAD-Rad18-HA show SUMO interaction (figure 4.8). SUMO interaction of the truncated versions of Sec27, Rad5, Rrb1, Dbp10 and Drs1 could not be observed (all not shown). GAD-Sap1 was chosen from the bioinformatical screen as an established SUMO interactor [Hannich et al., 2005]. Slx4, Tdp1 and Top1 were selected from the bioinformatical SIMb screens (tables 4.13, 4.19), despite their putative SIMb are either predicted to reside in a globular protein region (Slx4) or show low

4. Results

Figure 4.7. α -HA signal intensity (3F10) as a measure for protein expression level. Expression of GAD fusions of Rad18, Rfc1, Drs1, Dbp10, Rrb1, Rad5, Sec27 and unligated GAD-HA in *Saccharomyces cerevisiae* strain JD47-13C (table 4.29). Cell extracts were lysed with either the glass bead method (left) or direct boiling (right) (section 3.2.13). GAD-Sec27-HA, GAD-Rrb1¹⁻⁵⁴⁰-HA and GAD-Dbp10-HA are not expressed.

relative conservation scores (Tdp1, Top1). Slx4, Tdp1 and Top1 were cloned using the Gateway™ protocol (section 3.2.11).

Yeast two-hybrid experiments are interpreted as follows: Growth on SD-LW serves as an indicator to correctly expressing both GAD and GBD fusion proteins. Growth on other plates was used as an indicator to SUMO interaction. Growth intensity and the plate type in the order SD-LWH < SD-LWH+3AT < SD-LWA are used as a measure for interaction intensity. Tdp1 shows interaction with all Smt3 versions on SD-LWH, whereas its interaction to Smt3 Δ 97 is suppressed upon 3-AT addition. The interaction of Tdp1 for conjugatable Smt3 is stronger than the Smt3 Δ 97 truncation and responsible for growth on SD-LWH+3AT and SD-LWA plates. GAD-Rad5-HA, GAD-Rrb1¹⁻⁶¹⁵-HA and GAD-Drs1-HA show no growth on other than SD-LW plates. Rfc1 has a preference for conjugatable Smt3, as strains expressing GAD-Rfc1-HA and GBD fusions of Smt3 and Smt3 \times 3 chains grow on SD-LWH plates. That growth is prevented upon addition of 5 mM 3-AT to the SD-LWH plates and on SD-LWA plates. From these plates, it cannot be concluded why Rfc1 is not interacting to Smt3 \times 4 chains. GAD-Rad18-HA expressing strains grow on SD-LWH plates (and more stringent plates) when additionally expressed with GBD fusions of Smt3, Smt3 \times 3 or Smt3 \times 4. 3-AT reduces growth of these transformants to a similar extent as on SD-LWA plates for Rad18, Tdp1 and Sap1. These growth phenotypes indicate SUMO interaction (Smt3 and Smt3 \times 3) with these fusions. Rad18 additionally interacts even better with the Smt3 \times 4 GBD fusion. Rad18 therefore shows more preference for SUMO chain interaction than for the mono-Smt3 moiety (GBD-Smt3 Δ 97).

4. Results

Figure 4.8. Rad18, Rfc1 and Tdp1 show SUMO interaction in yeast two-hybrid experiments. Results from yeast two-hybrid experiments are shown for Rad5, Rrb1, Drs1, Rfc1, Rad18, Tdp1, Sap1: Each spot on a plate corresponds to an independently grown transformant colony comprising one GAD and one GBD fusion protein expressing plasmid in *Saccharomyces cerevisiae* strain PJ69-4A. Equal results were obtained when yeast strain AH109 was used. Equal amounts from aqueous cell suspensions corresponding to an optical density of 10 OD₆₀₀ were spotted onto SD-LW (first column), SD-LWH (second column), SD-LWH supplemented with 5 mM 3-AT (third column) and SD-LWA plates (last column) and incubated for 4 days at 30°C. Each plate was spotted with three independently grown transformants expressing the GAD fusion protein and one shown transformant expressing only GAD as a control, respectively, and expressing the GBD fusion protein and one shown transformant expressing only GBD as a control, respectively. SD plates are labeled in a way that each row corresponds to a distinct GAD fusion protein and each column to a distinct GBD fusion protein expressed in the respective strain.

4.6.2. Verification of SUMO/SIM interaction in GST-SUMO pulldown assays

For confirmation of SUMO interaction for Rfc1 and Rad18, GST pulldown assays were performed (section 3.2.17). Sec27, Rad5, Rrb1, Dbp10, Drs1, Rfc1 and Rad18 were used as full length proteins with C-terminal 6×HA-tag (table 4.30). Tdp1 was omitted from this test, as the SIM candidates in Tdp1, Top1 and Slx4 were investigated in yeast two-hybrid studies after GST-pulldown assays had been completed for the first set of proteins. Nis1 was used as a positive SUMO interaction control [Hannich et al., 2005, Uzunova et al., 2007]. The respective genes were genetically altered with a sequence encoding a C-terminal 6×HA tag using a PCR-based epitope tagging technique (section 3.2.17) [Longtine et al., 1998, Knop et al., 1999, Janke et al., 2004]. For this study, the pYM14 plasmid bearing the kanMX gene from Tn903 was used as a template. This amplified PCR product provided resistance to the aminoglycosid antibiotic G418 upon recombination into the yeast genome [Janke et al., 2004].

Table 4.30. Epitope tagged proteins in full-length comprising the SIM sequence from the bioinformatical screen used for GST pulldown assays. pYM14 served as template for the PCR amplification of a cassette comprising 6×HA tag and kanMX6 selectable marker [Longtine et al., 1998, Knop et al., 1999, Janke et al., 2004].

Nis1-6HA	52 kDa	<input checked="" type="checkbox"/>

SUMO was expressed as GST protein fusion in *Escherichia coli*. An *E. coli* strain expressing GST alone was taken as a negative control. For the GST pulldown assay, *E. coli* strains expressing GST and GST-SUMO and the glass bead lysis protocol were used (section 3.2.13). GST and GST-SUMO were immobilized onto glutathion sepharose beads by applying the respective crude extracts to the glutathion sepharose matrix. Yeast strains expressing the 6×HA tagged proteins were incubated overnight at 30°C, harvested by centrifugation and lysed. Western blots indicate the HA signal intensity as a measure for protein expression levels (figure 4.9): Lanes correspond to different

4. Results

crude extracts from lysis using the glass bead lysis (green) or the direct boiling method (red). All labels in the figures omit the 6×HA tag for simplicity. Using 3F10 as α -HA antibody, the HA signal intensity can be taken as an indicator for protein expression in *Saccharomyces cerevisiae*. All 6×HA tagged proteins are expressed but with very different levels. The glass bead lysis method gives more specific bands for the respective protein and was therefore used in the GST pulldown technique. Direct boiling of the *Saccharomyces cerevisiae* cell pellets leads to ‘smearing’ of the expected α -HA signal.

Figure 4.9. Glass bead lysis gives crude extracts with more specific α -HA signal in western blots than from the direct boiling protocol. α -HA western blots after glass bead lysis (green, soluble fraction) and boiled crude cell pellets (red) of the respective *Saccharomyces cerevisiae* JD47-13C strains.

4.6.2.1. Comparison of various lysis buffer compositions for best α -HA signal depletion in GST-SUMO pulldown assays

Different lysis buffer compositions are reported among others [Uzunova, 2006, Miteva, 2007, Kurian, 2009], as protein expression, folding and stability can be influenced by solvent conditions. Inter- and intramolecular salt-bridges in proteins are mainly affected when shifted to a solvent with different effective polarity. To find the best suitable lysis buffer composition for the GST-SUMO pulldown approach, different amounts of sodium chloride were used in a preliminary test with and without use of triton-X as detergent. Four different buffer compositions were applied to determine the optimal conditions for GST pulldown assay performance of Fir1-6HA and Nis1-6HA as established SIP, hereafter referred to as “Fir1” and “Nis1” (table 4.10). The GST pulldown assay was performed with GST and GST-SUMO crude extracts (section 3.2.11). Wild-type *Saccharomyces cerevisiae* strain and strains expressing “Fir1” and “Nis1” were used in the GST pulldown assay as bait for the immobilized GST fusion proteins. The *Saccharomyces cerevisiae* strains were incubated and lysed (section 3.2.13).

4. Results

Table 4.10. Different lysis buffer compositions for best lysis performance in western blots. The different conditions vary in their sodium chloride content (“low salt” and “high salt”) and whether Triton X-100 was used. All buffers were supplemented with protease inhibitor and used at 4°C.

NaCl	150 mM	50 mM	150 mM	50 mM
EDTA	5 mM	5 mM	5 mM	5 mM
HEPES	50 mM	50 mM	50 mM	50 mM
Triton	-	-	1 %	1 %

Samples were taken from these crude extracts before (input) and after applying to the immobilized GST-SUMO fusion protein (flow-through, FT). The α -HA signal differences between these samples were checked in α -HA western blots (figure 4.11). The α -HA signal intensities were evaluated as FT/input ratio providing a measure for the efficiency of the GST pulldown.

Figure 4.11. Nis1 crude extract from glass bead lysis is a good positive control. Best α -HA signal depletion is observed for buffer “green”. Wild-type yeast strain JD47-13C, Fir1-6HA (“Fir1”) and Nis1-6HA (“Nis1”) were used in this GST pulldown assay. Different lysis buffer compositions were applied (table 4.10). Shown here are the different levels of α -HA signal with crude extracts before (input) and after applying (flow-through) to GST-SUMO immobilized on a sepharose matrix.

α -HA signal depletion with GST-SUMO and 6 \times HA tagged Nis1 is best under “high salt” lysing conditions and when triton is applied. Wild-type JD47-13C strain expressing no HA-tagged protein gave a slight non-specific signal at high molecular weight region in western blots and 3F10 antibody (figure 4.11).

4. Results

4.6.2.2. GST-SUMO pulldown depletes α -HA signals of Dbp10 and Drs1

Western blots of Dbp10-6HA (“Dbp10”) and Drs1-6HA (“Drs1”) after GST pulldown show α -HA signal depletion upon SUMO interaction (figure 4.12). Depletion of HA signal intensity was defined as the difference between GST and GST-SUMO flow-through fractions. That depletion is taken as a measure for the amount of recombinant protein removed upon binding to SUMO (Smt3). Ponceau colorization and α -Cdc11 immunoblotting verified that similar amounts of extracts proteins were applied. DBP10 and DRS1 constructs show no interaction with SMT3 constructs in the two-hybrid assay, whereas α -HA signal depletion for these constructs in GST-SUMO pulldown assays is shown with shorter X-ray film exposure or with crude extract dilutions applied (figure 4.12): Elution of the GST- and GST-SUMO-coated glutathion sepharose beads with 10 mM Glutathion/lysis buffer give differences in α -HA signal intensities between the GST and GST-SUMO lanes. The blots for Dbp10 and Drs1, therefore, indicate weak interactions with SUMO.

Figure 4.12. Dbp10 and Drs1 show α -HA signal depletion upon SUMO interaction. Dbp10 and Drs1 in their 6HA tagged versions were used in GST pulldown assays. Western blots were taken in two different x-ray film exposures (a/c, b/d) and different dilutions (a/b, c/d). α -HA signal depletion is regarded as a measure for recombinant protein removed from the applied crude extract upon SUMO binding.

4. Results

4.6.2.3. GST-SUMO pulldown shows SUMO interaction for Rfc1 and Rad18

Western blots for the GST-SUMO pulldown assays applied to Rfc1-6HA (“Rfc1”), Rad18-6HA (“Rad18”) and Nis1-6HA (“Nis1”) show weak α -HA signal depletion from the flow-through (FT) samples (figure 4.13). Elution with 10 mM glutathion after washing returned more HA-signal for Dbp10, Drs1 and Rad18 from beads coated with GST-SUMO than from those with GST alone. Repeated GST-SUMO pulldown assays for Rfc1 and Rad18 did not give reproducible results. Even repetitions of the GST-SUMO pulldown assay with lysis buffer with different sodium chloride contents (25 mM, 50 mM, 100 mM and 150 mM) did not provide a clear α -HA signal depletion for Rad18 or Rfc1. Nis1 was used as a performance control in GST pulldown assays with the same buffer and GST/GST-SUMO exposures as Dbp10, Drs1, Rfc1 and Rad18 (figure 4.13(d)): Nis1 signal depletion is observed between the input lane and either of the FT lanes and between the FT lanes of GST and GST-SUMO.

Figure 4.13. α -HA immunoblotting shows SUMO interaction for Rfc1 from α -HA signal depletion and for Rad18 from elution. GST-SUMO pulldown results for Rfc1 (in two different X-ray exposures 4.13(a), 4.13(a)), Rad18 (4.13(c)) and Nis1 as GST pulldown performance control (4.13(d)) show different levels of SUMO interaction.

The GST pulldown assay worked well under the used experimental conditions for the established SIP Nis1, as the conditions were optimized for Nis1/SUMO interaction (figures 4.11, 4.13(d)). For Rfc1 and Rad18 with SUMO interaction from the yeast two-hybrid results, however, the GST-SUMO pulldown assay did not give reproducible results. No results supporting SUMO interaction for Sec27-6HA, Rad5-6HA and Rrb1-6HA with SUMO were obtained in the GST-pulldown assays.

4. Results

4.6.2.4. Strategy for SIMa mutation in Rfc1

Rfc1/SUMO interaction was shown in yeast two-hybrid experiments (section 4.6.1). For a better understanding of the biological relevance of the SIMa in Rfc1, mutation studies were performed. Protein sequence comparison within a ‘narrow’ phylogenetic range showed three putative SIMs in close distance to each other in the amino terminal region (figure 4.14): A highly conserved sequence MVNISD (green bar, ‘SIM1’), the highly conserved VIDLDTE motif from the bioinformatical screen (red bar, ‘SIM2’) and a poorly conserved VIDVISE (blue bar, ‘SIM3’). SIM1 and SIM3 were not included in the bioinformatical results, whereas they follow the SIMa consensus pattern. SIM1 shows good absolute and relative conservation but is not so close to the SIMa pattern as is SIM3. However, they may show supporting SUMO binding function for SIM2.

Figure 4.14. Three SIM-like sequences in the Rfc1 amino terminal region from the bioinformatical SIMa and SIMb detection screens. Carboxy terminal extract from a ‘narrow’ MSA for Rfc1 (YOR217W). A highly conserved SIM-like sequence at the very amino terminus (green bar), the well-conserved putative SIMa/b from the bioinformatical detection screens (red bar) and a poorly conserved SIMa-like sequence VIDVISE (blue bar) are indicated.

For the identification of SIM functionality for Rfc1, amino acid mutations were introduced at the interface between hydrophobic and acidic stretch (figure 4.15). For yeast two-hybrid experiments, these residue mutations were introduced by site-directed mutagenesis into the coding sequence of the previously used GAD-Rfc1-HA plasmid (table 4.29 and section 3.2.10). The three putative SIM1, SIM2 and SIM3 are referred to in the order of sequence occurrence from the protein’s amino terminus. All seven possible SIM mutant permutations were used: Δ SIM1, Δ SIM2, Δ SIM3, Δ SIM1 Δ SIM2, Δ SIM2 Δ SIM3, Δ SIM1 Δ SIM3, Δ SIM1 Δ SIM2 Δ SIM3. The Gal4 activating domain (GAD) was expressed alone as a negative control (GAD-C1) or as N-terminal fusions to Rfc1 (positive control), Rfc1 Δ SIM1, Rfc1 Δ SIM2, Rfc1 Δ SIM3, Rfc1 Δ SIM1 Δ SIM2, Rfc1 Δ SIM1 Δ SIM3, Rfc1 Δ SIM2 Δ SIM3 and Rfc1 Δ SIM1 Δ SIM2 Δ SIM3. The Gal4 binding domain (GBD) was expressed alone as a negative control (GBD-C1) or as fusions to Smt3, Smt3 Δ 97, Smt3 \times 3 and Smt4 \times 4.

Figure 4.15. Nucleotide exchanges for selective mutation of the Rfc1 SIM-like sequences in *Saccharomyces cerevisiae*.

All final carboxy termini of Smt3 were Δ G97 truncated. *Saccharomyces cerevisiae* strains AH109 and pJ69-4A were co-transformed with plasmids expressing a GAD and a GBD fusion protein using the lithium acetate method (section 3.2.6). Equal volumes from these cell dilutions were spotted onto synthetic drop-out (SD) media plates lacking leucine and tryptophane (SD-LW). SD-LW plates additionally lacking histidine (SD-LWH), or SD-LWH plates with 5 mM 3-AT (SD-LWH+3AT) and SD-LW plates lacking adenine (SD-LWA) were used.

The occurrence of growth phenotype is regarded as a measure for SUMO interaction. Cell growth phenotype on SD-LW plates for all strains used served as control (figure 4.16). Cells were present in the spotted suspensions at comparable concentrations. Growth on SD-LWH plates is expected from the previous yeast two-hybrid experiments (figure 4.8). Additionally, growth is observed in strains expressing any GBD-Smt3 fusion. Growth is less suppressed for two transformants expressing GBD-Smt3 and GBD-Smt3 Δ 97 on SD-LWH+3AT plates than expected from previous experiments. The results from strains expressing GAD fusions of Rfc1 Δ SIM1, Rfc1 Δ SIM3 and Rfc1 Δ SIM1 Δ SIM3 are comparable with previous two-hybrid findings for GAD-Rfc1-HA: Those strains show growth where GBD fusions of Smt3 and Smt3 \times 3 are co-expressed with the respective GAD-Rfc1

4. Results

mutant. All other strains show no growth on plates other than SD-LW.

In conclusion, these two hybrid assays show that SIM2, which was initially identified in the bioinformatical SIMa and SIMb detection screens, represents a functional SIM for SUMO interaction, whereas the other two sequences tested do not contribute detectably to SUMO binding.

Figure 4.16. “SIM2” VIDLDT in Rfc1 from the bioinformatical SIMa and SIMb screens is responsible for SUMO interaction. Unmutated and mutated versions of GAD-Rfc1-HA were used together with different GBD constructs expressing GBD-C1 and fusions of Smt3, Smt3Δ97, Smt3×3 and Smt3×4. SD-LW plates served as internal transformant growth control.

4.6.3. Rfc1 SIM mutation may induce growth phenotype upon DNA damage

SUMO interaction has not yet been reported for Rfc1. With the SIM in Elg1 and the Elg1-RFC complex involved in SUMOylated PCNA binding, a functional SIM in Rfc1 may be relevant for RFC clamp loading activity [Parnas et al., 2010]. DNA replication and DNA damage repair may be negatively affected by an unfunctional SIM in Rfc1. Growth phenotype analysis of an *rfc1* SIM mutant strain is performed upon temperature stress and exposure to chemically induced DNA damage. Methyl methanesulfonate (MMS), Ebselen (2-phenyl-1,2-benzisoxazol-3(2*H*)-one) and hydroxy urea (HU) are reported as such chemical agents [Azad et al., 2012].

4.6.4. Verification of Rfc1 SIM/Smt3 interaction

MMS is a reported alkylating agent [Prakash and Prakash, 1977, Fortini et al., 2000, Lundin, 2005]. It alkylates deoxyribonucleotide phosphates (dNTP). MMS modifies guanine and adenine to 7-methyl guanine and 3-methyl adenine, respectively [Beranek, 1990]. These DNA damages are repaired by the base excision repair pathway (BER) and DNA alkyltransferase [Lindahl, 1990, Jiricny, 2006]. Cells with dysfunctional homologous recombination pathway (HR) were found to be sensitive to MMS treatment [Krogh and Symington, 2004]. MMS causes double-strand breaks (DSBs). DSBs are usually corrected either by non-homologous end joining (NHEJ) or the HR pathway [Weterings and Chen, 2008, West, 2003, Li and Heyer, 2008, Caldecott, 2008]. HU is an inhibitor to ribonucleotide reductase (RNR) and inhibits DNA replication by stalling the replication fork [Krakoff et al., 1968, Slater, 1973]. The mechanisms leading to this replication stall remain unclear.

The underlying mechanisms how Ebselen exposure to yeast cells lead to DNA double-strand breaks are still unknown. It was found that Ebselen leads to RNR inhibition like HU treatment. MMS, HU and Ebselen are used in growth phenotype analysis when effects on DNA damage repair are expected [Azad et al., 2012].

This might be the case for a dysfunctional SIM in the *rfc1* mutant strain, if the SIM plays a crucial role in DNA damage repair pathways.

4.6.4.1. The SIMa mutation is integrated into RFC1 via two-step gene replacement

Gene replacement was performed with the two-step gene replacement method (section 3.2.18) [Sikorski and Hieter, 1989, Widlund and Davis, 2005]. A nucleotide sequence 1 kB upstream of the RFC1 gene and 705 nucleotides of its coding sequence was amplified by

4. Results

PCR. Primers (table 2.4) were used to comprise a mutant version of SIMa ('SIM2', red), which was shown earlier in this thesis to be responsible for Rfc1/SUMO interaction in the two-hybrid assay. A silent SalI restriction site (blue) is introduced close to the SIMa mutation site to ease identification of correct clones.

Figure 4.17. Strategy for a SIMa mutagenesis for RFC1 from the bioinformatical screens. The motif is changed from VIDLDT to VIDAAT. A SIM mutation VIDAAT, instead, lost that functionality in yeast two-hybrid experiments. Three nucleotides (red) were exchanged for a double-alanine translation. Silent mutagenesis introduced a unique SalI restriction site (blue) to allow mutant allele screening from many transformants by analytical PCR followed by SalI restriction (figure 4.20).

The amplicon was introduced into a pBluescript-based integrative vector pRS306 with *URA3* selectable marker (figures 4.18, 4.19). The multi-cloning site (MCS) is embedded in a sequence encoding a segment (alpha peptide) of the *lacZ* protein. The MCS is indicated in figure 4.18 and figure 4.19 by KpnI and NotI sites. They were used for the cloning step. Amplicon restriction using the unique SalI restriction site introduced by silent mutagenesis and Sanger sequencing confirmed the plasmid sequence.

Figure 4.18. First step in the two-step gene replacement cloning strategy. Simplified pRS306 vector map (adapted from [Sikorski and Hieter, 1989]). The shuffle vector comprises ampicillin (green) and *URA3* (blue) selectable markers. A *lacZ* gene (red) is preceded by a multi-cloning site indicated by KpnI (violet) and NotI (turquoise) restriction sites. The insert depicted below (gold) was classically cloned and comprises 1 kb upstream sequence and 705 bases of the Rfc1 coding sequence (green). Compare figure 4.19 for further information.

4. Results

Figure 4.19. Vector map for the integratable shuffle vector *rfc1*:pRS306. The insert is cloned into a sequence encoding the so-called alpha-peptide of *lacZ* thereby preventing alpha-peptide expression and thus the generation of functional *lacZ* by alpha-complementation. This allows visual selection of integrants using the blue/white technique of transformed *Escherichia coli* cells on LB plates supplemented with ampicillin and X-Gal. A unique *Bam*HI restriction site is introduced by the vector for linearization and a unique *Sal*I restriction site for analytical PCR and restriction analysis of integrants.

Linearization of the vector using the unique *Bam*HI site within the *RFC1* coding region directs integration at the endogenous *RFC1* gene locus upon transformation of wild-type yeast cells. Correct integration of the plasmid by homologous recombination results in a tandem array of a 5' truncated wild-type allele of *RFC1* and a full-length mutant allele of *RFC1* with promoter flanked by the selectable *URA3* marker. Selection on SD plates lacking uracil, followed by counter-selection on SD plates with 0.1% 5-fluoro-orotic acid gives the desired strain with the wild-type *RFC1* gene replaced by the mutant allele (section 3.2.18) [Cregg and Russell, 1998, Widlund and Davis, 2005]. Replacement was checked by amplification and successive *Sal*I restriction (figure 4.20, table 2.4). This was confirmed by Sanger sequencing.

The forward primer binds about 1 kB upstream the *RFC1* gene and the reverse primer to a nucleotide sequence downstream of the integrated allele. The *Sal*I restriction site was introduced right after the mutagenized SIMa (figure 4.17). Amplification of that 2.8 kB nucleotide sequence with subsequent restriction with *Sal*I verified the correct *rfc1* SIMa mutant strain (figure 4.20).

4. Results

Figure 4.20. Amplification and subsequent *Sal*I restriction helped identify a correct SIM mutant integrant. Amplification of a nucleotide sequence comprising 1 kb upstream the *RFC1* gene and about 1.8 kb of its coding sequences is performed with integrants as template. Primers are designed to bind in the front part of the integration and in the ‘wild-type’ coding sequence behind the integrated nucleotide sequence. An amplicon of 2.8 kb size is expected. *Sal*I restriction verifies the presence of the introduced mutations by producing 1.7 kb and 1.1 kb fragments. This was confirmed by Sanger sequencing.

4.6.5. Relevance of Rfc1 SIMa/SUMO interaction

A biological relevance for a SIMa/SUMO interaction in *RFC1* can be investigated in thermal or chemical stress tests. The occurrence of growth phenotype for a *rfc1* SIMa mutant JD47-13C strain is regarded as a measure for dysfunctional or at least hindered stress response. Lack of growth, on the other hand, is no means for lack of interaction relevance. Stress of the mutant strain may also be compensated by other pathways.

4.6.5.1. No growth phenotype upon thermal stress

A mutant *Saccharomyces cerevisiae* strain with dysfunctional SIMa in the *RFC1* gene was constructed. Growth phenotype analyses are performed with different aqueous cell suspensions of the mutant strains as described by Azad *et al.* [Azad *et al.*, 2012]. Growth characteristics of several independent isolates of the *rfc1* mutant strain were analyzed in comparison to the congenic wild-type strain (figures 4.21, 4.22, 4.23, 4.24). A preliminary growth test on YPD plates showed no difference whether cells were incubated at 30°C or 37°C. Plates were checked after 24h, 48h, 72h and 96h of incubation (figure 4.21). Thermal stress alone does not induce growth defects in the *rfc1* SIM mutant strain. Overall growth in the different strains is reduced by incubation at 37°C instead of 30°C.

4. Results

Figure 4.21. No observable growth phenotype of *rfc1* SIM mutant upon thermal stress. Wild-type (wt) and SIM mutant strains (1, 2) were spotted onto YPD plates undiluted (10^0) and in 10^{-1} , 10^{-2} and 10^{-3} dilutions and incubated at 30°C (top row) and 37°C (bottom row). Shown here are the respective plates after 24h, 48h, 72h and 96h. The left lanes correspond to an wild-type JD47-13C strain and lanes 1 and 2 to independently grown mutant strains, all spotted in dilutions from the top down.

4.6.5.2. No observable growth phenotype under chemical stress: methyl methanesulfonate

MMS was freshly dissolved in dimethyl sulfoxide (DMSO) and added to YPD plates at a final concentration of 0.01%. Wild-type and *rfc1* SIM mutant strains were used in the same dilutions as for the previous thermal stress test (section 4.6.5.1, figure 4.21). Growth phenotype was checked after 24h, 48h, 72h and 96h incubation at 30°C and 37°C, respectively (figure 4.22). No growth phenotype can be observed as difference between wild-type and mutant strains (figure 4.22).

4. Results

Figure 4.22. No observable growth phenotype of *rfc1* SIM mutant upon MMS exposure. Wild-type (wt) and SIM mutant strains (1, 2) were spotted onto YPD plates supplemented with 0.01% MMS in 10⁰, 10⁻¹, 10⁻² and 10⁻³ dilutions and incubated for 4 days at 30°C (top part) and 37°C (bottom part).

4.6.5.3. Observable growth phenotype under chemical stress: hydroxy urea

Cells in dilutions of 10⁰, 10⁻¹, 10⁻² and 10⁻³ from the same culture were spotted onto YPD plates supplemented to different final concentrations of hydroxy urea (HU) (10 mM, 40 mM, 70 mM and 100 mM) [Azad et al., 2012]. YPD/HU plates were incubated at 30°C and 37°C. Growth phenotype was checked after 24h, 48h, 72h and 96h (figure 4.23). Strong growth phenotype can be observed on plates incubated at 37°C, especially with 40 mM and 70 mM HU concentration. On those plates, the wild-type strain shows increased growth compared to the mutant strains. Similar growth phenotype is observable on plates incubated at 30°C at longer incubation and with increased HU concentrations.

4. Results

Figure 4.23. Observable growth phenotype of *rfc1* SIM mutant strain upon exposure to hydroxy urea. Wild-type (wt) and *Rfc1* SIM mutant strains (1, 2) were spotted in 10^0 , 10^{-1} , 10^{-2} and 10^{-3} dilutions. YPD plates supplemented with final concentrations of hydroxy urea (HU) of 10 mM, 40 mM, 70 mM and 100 mM were used. Incubation at 30°C (left part) and 37°C (right part) was recorded after 24h, 48h, 72h and 96h. The plates are arranged with increasing HU concentration from top down and with increasing incubation time from left to right. Growth phenotype is shown upon HU exposure and increased temperatures, but is already visible at 30°C with increased HU concentrations.

4. Results

4.6.5.4. Observable growth phenotype under chemical stress: Ebselen

Different Ebselen (2-phenyl-1,2-benzisoselenazol-3(2*H*)-one) concentrations of 10 μ M, 40 μ M, 70 μ M and 100 μ M were supplemented to YPD plates. Cells of the wild-type and *rfc1* SIM mutant strain were spotted in dilutions of 10^0 , 10^{-1} , 10^{-2} and 10^{-3} onto these YPD/Ebselen plates and incubated at 30°C and 37°C, respectively (figure 4.24). At 37°C, all strains spotted show decreased growth. The decrease is stronger with increasing Ebselen concentrations or increased temperature. It can be concluded from these experiments, that the *rfc1* SIM mutant exhibits a mild hypersensitivity to several genotoxic agents.

Figure 4.24. Observable growth phenotype of *rfc1* SIM mutant strain upon Ebselen exposure. Wild-type (wt) and SIM mutant strains (1, 2) were spotted in 10^0 , 10^{-1} , 10^{-2} and 10^{-3} dilutions onto YPD plates supplemented with different concentrations of Ebselen (10 μ M, 40 μ M, 70 μ M and 100 μ M) and incubated for 4 days at 30°C (left part) and 37°C (right part). Growth phenotype is obvious at 37°C already with 10 μ M and 40 μ M Ebselen as growth difference between wild type and mutant strains.

5. Discussion

5.1. General aspects of bioinformatical motif discovery

Many regulatory processes are mediated by short linear motifs (SLiMs) which are usually found in unstructured linker regions. These highly conserved instances form short, mainly hydrophobic sequences of 3–10 amino acids which adopt a defined three-dimensional conformation upon interaction with their prefolded partner. Partner binding affinity is reduced compared to the binding between prefolded structures. SLiMs, therefore, allow regulation of biological processes. Such regulatory processes are involved in pathways connected to the ubiquitin proteasome system (UPS), the small ubiquitin-like modifier (SUMO) or Atg8. Mechanistical and structural similarities in conjugation cascades and recognition show the importance of these pathways for cellular survival. Whereas ubiquitin recognition involves different classes of prefolded structures, decoding of SUMOylated proteins depends on the noncovalent interaction to a SUMO interacting motif (SIM). The three different SIM types (SIMa, SIMb, SIMr) may differ in their consensus patterns, but also show common characteristics. These characteristics are used for a bioinformatical SIM detection approach described in this thesis.

AIMs show similar characteristics to SUMO interacting motifs. These short stretches are highly conserved and are located in unstructured, well solvent-accessible protein regions. One property of short motifs that complicates their bioinformatical detection is the narrow phylogenetic range of conservation. In more distantly related species, both SIMs and AIMs often disappear and/or reappear at a different position.

The basic assumptions for a bioinformatical detection approach are the same for both SIMs and AIMs. The number of established motifs is less for AIMs than for SIMs. This and the short sequence of AIMs reduces the sequence information in form of a consensus profile or pattern. The bioinformatical approach to detecting AIMs might therefore be less effective in enriching true-positive motifs than is the SIM approach. The descriptive part deals with the SIM detection approach. The same assumptions and methods were also applied in the AIM detection approach.

Pattern-based screens in sequence databases with only a consensus pattern return large numbers of false-positive sequences. Discrimination of functional motifs from spurious pattern matches is performed through additional criteria regarding their conservation

5. Discussion

and structural context. Biological function is under strong evolutionary constraint. Therefore, the short SIM sequences are usually passed on to succeeding generations more or less as a whole. For that reason, most functional SIMs are highly conserved over several phylogenetically related species. Disordered regions in general lack the constraints associated with the conservation of folded structures. Thus, functional residues in SIM sequences are more conserved than their surrounding. Whereas folded structures show high contents of hydrophobic residues, acidic residues are enriched in unstructured regions. This is reflected in the SIM and AIM consensus sequences in which the conserved hydrophobic part is preceded or followed by acidic residues. Single mutations in the coding sequences allow SIMs to vanish, to emerge at a different position or to change its consensus type.

Whereas bioinformatics may be applied to a wide range of functional SIMs, these ‘atypical’ cases of poorly conserved, but still functional SIMs may not be identified by the bioinformatical approach described in this thesis. This approach will also neglect those SIMs, that are readily solvent-accessible despite being within or close to folded structures. Vice versa, this approach is not exclusive to false-positive motif-like sequences.

5.2. Experimental findings from the bioinformatical results

For the experimental interaction studies, it was important to not just use the SIM-containing peptide. One important criterion for the biological relevance of a putative SIM is its accessibility for SUMO interaction. For an isolated peptide, this condition would always be fulfilled - even if the SIM-like motif is biologically meaningless because it is found within the buried core of a folded domain. On the other hand, many of the SIM-containing proteins are unusually big and difficult to handle and express under experimental conditions. For that reason, an intermediate approach was used: Short proteins were used in their entirety, while big proteins were shortened by using truncations at defined domain boundaries. In all cases, the SIM-containing part of the protein was used within its usual sequence context. In the biologically interesting case of Rfc1, it was also tested if the observed SUMO binding by the protein was really due to the motif identified in the bioinformatical screen. A mutation within the predicted SIM region abrogated the SUMO interaction.

Putative SIM sequences in Rad5, Rrb1, Dbp10, Drs1, Rfc1 (all SIMa), Slx4, Top1, Tdp1 (all SIMb) and Rad18 (SIMr) were finally selected for experimental interaction studies. Yeast two-hybrid experiments show SUMO interaction for Tdp1, Rfc1 and Rad18. SUMO/SIM interaction could be confirmed for Rfc1 with SIM mutants in yeast

5. Discussion

two-hybrid experiments. GST-SUMO pulldown experiments further suggested SUMO interaction for Dbp10 and Drs1. Rfc1/SUMO and Rad18/SUMO interaction were also shown in these experiments.

SUMO/SIM interaction of Rfc1 was investigated in phenotype analysis. A *rfc1* SIM mutant strain was exposed to thermal and thermal/chemical stress. The chemical compounds methyl methanesulfonate, hydroxy urea and Ebselen were used for their DNA damaging effects [Azad et al., 2012]. Hydroxy urea and Ebselen caused observable growth defects (sections 4.6.5.3, 4.6.5.4).

Rad18/SUMO interaction was meanwhile shown by Parker and Ulrich for the same SIMr as from the bioinformatical SIM detection screen [Parker and Ulrich, 2012].

5.3. Discussion of exemplary results

5.3.1. Dbp10/SUMO and Drs1/SUMO interaction

5.3.1.1. Biological context of Dbp10 and Drs1

The *Saccharomyces cerevisiae* ribosome complex is composed of two subunits, 40S and 60S [Mager et al., 1997]. These subunits in turn consist of different ribosomal RNAs (rRNA) and ribosomal proteins (RP). Ribosomal biogenesis is a multi-step process. In *Saccharomyces cerevisiae*, there are 19 RNA helicases among which Dbp2, Dbp3, Dbp6, Dbp7, Dbp9, Dbp10 [Burger et al., 2000], Drs1 [Ripmaster et al., 1992, Ripmaster et al., 1993], Mak5, Mtr4 and Spb4 are involved in maturation of the pre-60S ribosomal particle in the nucleolus. They are recruited in a hierarchical manner to the pre-ribosomal particle at different stages of the biogenesis [Saveanu et al., 2003, Talkish et al., 2012]. Their molecular functions are unknown. During biogenesis, the pre-ribosomal particle is transferred from the nucleolus to the nucleoplasm and further to the cytoplasm for maturation. Yeast mutants with defects in their deconjugation pathways also develop defects in the pre-60S ribosomes [Panse et al., 2006]. Panse *et al.* also showed that many biogenesis factors are SUMOylated in this pathway [Panse et al., 2006]. SENP3-depleted cells accumulate pre-60S ribosomal particles in the nucleolus, indicating that the release into the nucleoplasm is dependent on deSUMOylation [Finkbeiner et al., 2011].

5.3.1.2. Experimental validation of SUMO interaction for Dbp10 and Drs1

The bioinformatical SIMa detection screen gave putative SIM instances with moderate profile scores in Dbp10 (VIEYSS, 3.296) and Drs1 (VPILDS, 3.481, tables 4.10, 4.11). These motif-like sequences show promising values for absolute, relative and background

5. Discussion

conservation. They are additionally predicted to reside in unstructured regions. Yeast two hybrid experiments with nucleotide sequences comprising the first 1529 (Dbp10) and 1731 nucleotides (Drs1) were performed. There was no detectable SUMO interaction. GST-SUMO pulldown assays were performed with the C-terminal HA tagged full length versions. Observed α -HA signal depletion signal indicates SUMO interaction for both proteins (figure 4.12). Elution efficiency of bound material from immobilized GST-SUMO depended on the applied pulldown conditions. Pulldown results suggest SUMO interaction for both proteins.

Dbp10 and Drs1 belong to the DEAD box family of proteins. ATP-binding and helicase domains of Dbp10 and Drs1 indicate functional roles in early steps of the biogenesis pathway [Bernstein et al., 2006]. With SUMOylation as checkpoint control in ribosomal biogenesis, SUMO/SIM recognition of Dbp10 or Drs1 may be plausible.

A conclusion whether there is a biological relevant SUMO interaction for these proteins is not possible. The mechanisms that assemble the pre-60S ribosomal particle in the orchestration of ribosome assembly factors are not understood. Additionally, the mechanisms of SUMOylation-dependent checkpoint control or an involvement of Dbp10 or Drs1 are still unknown.

5.3.2. Tdp1/SUMO interaction

5.3.2.1. Biological context of Tdp1 and Top1

Topoisomerase I (Top1) is involved in DNA replication and transcription. It releases the topological stress upon DNA supercoiling in front of the replication fork by transient induction of single-strand breaks (SSBs). Top1 reversibly forms a thioester bond between its active tyrosine (Tyr-127) and the DNA 3'-end to form a covalent "cleavage complex" [Wang, 2002, Pommier et al., 2003]. This step allows DNA stress release through rotation of the DNA double helix around the Top1-DNA bond. In a second step, Top1 religates the cleaved DNA ends to re-establish the original DNA double-strand. Cleavage complexes are short-living intermediates, as the DNA religation step is faster than the Top1-DNA bond formation step. Endogenous and exogenous factors provoke "trapping" of the cleavage complex leading to SSBs [Pourquier et al., 1999]. These cytotoxic DNA lesions can be further transformed into a double-strand break (DSB) upon collision with a replication fork [Tsao et al., 1993, Strumberg et al., 2000, Pommier et al., 2003]. Tyrosyl-DNA phosphodiesterase 1 (Tdp1) cleaves Top1 from the 3'-phosphotyrosyl-DNA intermediate [Yang et al., 1996, Pouliot et al., 1999, Pouliot et al., 2001, Champoux, 2001, Debethune et al., 2002]. The 3'-phosphate end is then further processed by an 3'-

5. Discussion

phosphatase such as polynucleotide kinase phosphatase (PNKP) [Strumberg et al., 2000]. Top1 is ubiquitinated for its 26S proteasomal degradation as a response to transcription blocks and is independent from replication [D'Arpa and Liu, 1995, Fu et al., 1999, Desai et al., 2001, Desai et al., 2003]. Ubiquitination occurs at K117 and K153, whereas ubiquitination competes with SUMOylation at these residues [Mao et al., 2000, Horie et al., 2002].

5.3.2.2. Experimental validation of Tdp1/SUMO interaction

The bioinformatical SIMb screen were trained on SIMb such as the ones in Uls1 TIDLT and Wss1 VIDLT. Different putative SIMb were selected from the results (figures 4.14, 4.15). The sequences of putative SIMb in Top1 and Tdp1 (IIDLT) look the same. However, the different numbers of homologous sequences in the Saccharomycetales MSA give different profile scores: 6.179 for Tdp1 and 4.023 for Top1. The Top1 SIMb candidate shows low overall conservation. By contrast, the SIMb in Tdp1 is comparable in profile score, conservation and structural context to the established SIMb in Uls1 and Wss1. There is no clear preference to decide from the disorder prediction, whether Tdp1 or Top1 is more likely to reside in an unstructured protein region: GlobPlot gives better hints for Top1, whereas IUPred tends to assign Tdp1 more-likely as disordered. However, the IUPred algorithms have been found more trustworthy for SIMs throughout the study. This may be a borderline case for the structural context assignments for a bioinformatical SIMb detection.

Tdp1 and Top1 were investigated as putative SIPs in yeast two-hybrid experiments. Full-length coding sequences were used. Experimental results show a binding preference of Tdp1 for conjugatable Smt3, as interaction only occurs for GAD-Tdp1/GBD-Smt3 and GAD-Tdp1/GBD-Smt3 \times 3 (figure 4.8). Whereas the Smt3 chain is Δ 97 truncated, the single Smt3 moiety is not. According to the yeast two-hybrid results, Tdp1 does not appear to bind to isolated Smt3. One possible interpretation of this discrepancy would be a low-affinity SUMO binding by the SIM of Tdp1, which requires another contact between Tdp1 and the SUMOylated protein for robust interaction.

SIM mutations in Tdp1 were not checked for SUMO interaction. Whereas Tdp1 was found to interact with SUMO, Top1 was not.

A SIMb in Tdp1 might play a role in the recognition of SUMOylated Top1 prior to Tdp1 mediated Top1-DNA bond cleavage. The circumstances behind that interaction and its relevance for Top1 release from DNA or for DNA replication as a whole still remain unclear.

5.3.3. Rfc1/SUMO interaction

5.3.3.1. Biological context of Rfc1

The replication factor C (RFC) complex is an essential component of the DNA replication and DNA damage repair pathways. This complex is a heteropentameric ring complex and composed of Rfc1–5 subunits. It is responsible for loading a ring-shaped replication factor, the proliferating cell nuclear antigen (PCNA), onto DNA [Cullmann et al., 1995, Gomes and Burgers, 2001, Yao, 2003, Bowman et al., 2004, Kelch et al., 2011]. The carboxy terminal domains of the subunits hold each other for ring-complex formation. The N-terminal domains are responsible for DNA binding [Cullmann et al., 1995]. The Rfc1 subunit is the largest one and has amino and carboxy terminal extensions compared to the other subunits. The Rfc1 carboxy terminal domain extension packs against Rfc5 as a switch for ring completion of the RFC complex [Beckwith and McAlear, 2000, Jeruzalmi et al., 2001, Bowman et al., 2004]. Subunits Rfc2–5 were found to be involved in PCNA opening and unloading from DNA. Deletion of the Rfc1 amino terminal sequence has no observable replication phenotype, but shows increased PCNA unloading activity from DNA [Yao et al., 2006]. Other RFC-like complexes are known, in which the Rfc1 subunit is replaced by another protein: An Rfc1/Rad24 exchange in *Saccharomyces cerevisiae* forms a clamp loader complex required for checkpoint control during S-phase [Green et al., 2000]. That Rad24–RFC complex also acts as clamp loader of the 9–1–1 complex onto DNA damage sites [Lindsey-Boltz et al., 2001, Bermudez et al., 2003, Parrilla-Castellar et al., 2004, Delacroix et al., 2007, Lee et al., 2007]. A Ctf18–RFC complex is required for sister chromatid cohesion [Hanna et al., 2001, Mayer et al., 2001, Naiki et al., 2001]. An Elg1–RFC complex contributes to chromosome stability and suppresses chromosomal rearrangements [Kanellis et al., 2003, Bellaoui et al., 2003, Ben-Aroya et al., 2003, Parnas et al., 2009]. Elg1–RFC is involved in PCNA unloading after replication [Parnas et al., 2009, Kubota et al., 2013]. Elg1 is an SUMO interacting protein, bearing several SIMs and promoting a preferential association with SUMOylated PCNA [Parnas et al., 2010, Parnas et al., 2011].

5.3.3.2. Experimental validation of Rfc1/SUMO interaction

A SIMa VIDLDT was found in Rfc1 by its significant profile score (4.185 and 4.530) in the bioinformatical SIMa and SIMb detection screens (tables 4.10, 4.11, 4.14, 4.15). Its sequence can be interpreted as an intermediate between the consensus sequences in Fir1 (VILLDE) and the SIMb consensus sequence of the PIAS proteins (VIDLT) (table 1.1) [Song et al., 2004, Hannich et al., 2005, Hecker et al., 2006, Uzunova et al., 2007]. The

5. Discussion

SIMa in Rfc1 has promising values for absolute, relative and background conservations in the bioinformatical screens. Additionally, it was predicted to be located most likely in an unstructured region.

Yeast two-hybrid experiments used a fragment comprising the first 705 nucleotides of the Rfc1 coding sequence. The results show Rfc1/SUMO interaction for this segment. Visual inspection of the Saccharomycetales MSA of Rfc1 showed the well-conserved SIM from the bioinformatical screen in a more variant protein region (table 4.14). Additionally, there are two SIM-like regions in close to the one from the screen — a highly conserved MVNISD sequence preceding and a nonconserved SIM consensus VIDVSE following that motif (figure 5.1). All three sequences match the SIMa consensus pattern.

Figure 5.1. An excerpt from the Saccharomycetales MSA of Rfc1 shows three SIM-like sequences. A highly conserved MVNISD sequence (green), the SIMa VIDLDT from the bioinformatical screen (red) and a poorly conserved VIDVSE sequence (blue). All SIM-like sequences follow the SIMa consensus pattern.

The ‘flanking’ SIM sequences are not included in the final bioinformatical results. The former may give no good profile score, whereas the latter misses the applied conservation restrictions. However, a supporting role of these motifs for a Rfc1/SUMO interaction cannot be excluded. Therefore, mutations are introduced into the Rfc1 yeast two-hybrid construct (table 4.15). Rfc1/SUMO interaction is only observed for the SIMa candidate from the bioinformatical screen. Phenotype analysis of a SIM mutant *rfc1* strain was performed upon thermal stress and thermal/chemical stress. A growth phenotype is only observed for the SIM-mutant strain upon exposure to DNA damage-inducing agents.

On the one hand, these data suggest that a SIM in Rfc1 is biologically relevant in DNA damage response or DNA damage repair. On the other hand, it cannot be excluded that the mutant introduced to Rfc1 affects translation, folding or stability of the protein, which might also explain the observed phenotype. To exclude whether the protein sequence alteration alone reduces PCNA clamp loading activity, different experiments would have to be performed: The functional SIMa could be replaced by the sequence of a different SIM consensus type. SIM relevant Rfc1 function should be restored.

Parnas *et al.* used an experiment to show the biological relevance for a SIM in Elg1.

5. Discussion

This SIM is shown to be involved in the process of unloading SUMOylated PCNA from DNA [Parnas et al., 2010].

Similar experiments for Rfc1 and SIM mutant *rfc1* strains could investigate whether the SIM in Rfc1 has a comparable impact on loading SUMOylated PCNA onto DNA as Elg1 has on unloading it. Parnas *et al.* performed Flag-pulldown assays of Elg1 constructs against SUMO-PCNA. They showed that Elg1 has a preference for binding SUMOylated PCNA [Parnas et al., 2010]. Similar to this experiment, Rfc1–SIM/SUMO–PCNA interaction should have an depleting effect on Rfc1 in the presence of SUMOylated PCNA. An *rfc1* SIM mutant construct should not show that effect. In another experiment, SUMOylated PCNA interaction could be restored in the *rfc1* SIM mutant by insertion of a SIM sequence of different consensus type to the original SIM position in the sequence.

5.3.4. Rad18/SUMO interaction

5.3.4.1. Biological context of Rad18

The heterodimeric Rad6–Rad18 protein complex monoubiquitinates the proliferating cell nuclear antigen (PCNA) at a highly conserved lysine (K164) in response to DNA damage [Hoege et al., 2002, Stelter and Ulrich, 2003, Kannouche et al., 2004, Bienko et al., 2005]. This step is important for translesion synthesis as an initial signal for DNA damage repair [Bailly et al., 1997, Hoege et al., 2002, Stelter and Ulrich, 2003, Kannouche et al., 2004, Bienko et al., 2005]. Extension of that monoubiquitin modification to a ubiquitin chain activates an error-free damage repair pathway [Hoege et al., 2002]. This active site K164 can also be SUMOylated by the SUMO E3 Siz1 [Hoege et al., 2002, Stelter and Ulrich, 2003]. SUMOylation at this position is observed during S phase and was shown to interact with Srs2 helicase which in turn inhibits unwanted recombination with Rad52 filaments [Hoege et al., 2002, Pfander et al., 2005, Papouli et al., 2005, Burkovics et al., 2013]. SUMOylation therefore acts as a competitor to ubiquitin to prevent unscheduled recombination events by enhancing Srs2 helicase binding during S phase [Papouli et al., 2005, Pfander et al., 2005, Parker et al., 2008]. Parker and Ulrich recently found that SUMOylated PCNA serves as a substrate for the *Saccharomyces cerevisiae* Rad18 ubiquitin ligase and that the SUMO binding step is mediated by a SIMr in Rad18 [Parker and Ulrich, 2012]. In this study, the same SIMr was found in the bioinformatical SIMr detection screen. SUMO/Rad18 interaction was also detected. Rad18 was proposed to mediate the cooperation between S phase-associated (mono-) SUMOylation and the DNA damage-induced ubiquitination of PCNA. Ubiquitination

5. Discussion

of SUMOylated PCNA may be important during replication, when replication problems or DNA damage occur.

5.3.4.2. Experimental validation of Rad18/SUMO interaction

Rad18 was tested in yeast two-hybrid experiments in form of a nucleotide sequence comprising the first 801 and the putative SIMr coding sequence. The results show Rad18 interaction with Smt3 and with 3×Smt3 and 4×Smt3 chains. The interaction with 4×Smt3 chains is the strongest (figure 4.8). Full-length Rad18 was used in GST-SUMO pulldown experiments (section 4.6.2). Rad18/SUMO interaction is mainly detected as α -HA signal depletion after exposure of HA-tagged Rad18 to immobilized GST and GST-SUMO as bait.

The α -HA signal difference after elution of immobilized material indicates weak SUMO interaction. Washing of immobilized material is the most sensitive step of the pulldown experiment. Therefore, α -HA signal intensities for Rad18 are significantly reduced in that experimental step. Putative differences in α -HA signal intensities are hard to detect. The GST-SUMO pulldown results are therefore a weak support to the clear yeast two-hybrid results. The Rad18/SUMO interaction via this SIM is very weak. Yeast two-hybrid experiments show a clear preference for Rad18 towards 4×SUMO chains. This is not covered by the GST-SUMO pulldown experiments with only a single SUMO moiety provided. SUMO binding may be therefore only sufficient when other binding factors are involved. Rad18 SIM/SUMO interaction is meanwhile confirmed by the works of Parker and Ulrich [Parker and Ulrich, 2012]. They showed that Rad18 interacts quite well with SUMOylated PCNA but hardly with isolated SUMO. This may explain, why GST-SUMO pulldown assays for Rad18 gave no clear result.

5.4. The application of analogous methods for a bioinformatical AIM detection approach

The number of established AIMs is low compared to the number of established SIMs. AIMs and SIMs are found in the same structural context. That is why a bioinformatical AIM approach was designed with analogous methods as for the SIM detection approach (tables 4.26 and 4.27).

AIM sequences seem to be not as strict to a consensus as are SIMs. The conservation characteristics of established AIM are found similar to those for SIMs, whereas the applied bioinformatical methods allow no clear judgement, whether an established AIM

is predicted as unstructured, non-globular or globular.

5.5. General aspects of the applied bioinformatical approach

The basic assumptions of what features constitute a good SUMO interacting motif are most relevant for the results of the bioinformatical SIM detection approach. This approach is suited for a detection of SIM which fit to these basic assumptions regarding conservation and structural context. Biologically relevant motifs in general are believed to be conserved among a certain phylogenetic range. SIMs which show less absolute conservation, which lie next to other conserved protein segments or which lie inside structured protein regions may not be detected. Biologically relevant SIMs like these exist, but are hard to distinguish from false-positive SIM candidates from the bioinformatical screen. The number of false-positive SIMs would be increased with a modification of the approach to yield more SIMs with ‘atypical’ conservation levels. While experimental methods are good at finding proteins and peptides that are physically able to interact with SUMO under the given experimental conditions, the bioinformatical approach is able to find SIMs that are selected for SUMO binding. While the latter set might be smaller than the former, it should be enriched for SIMs with biologically important functions.

5.6. General aspects of experimental validations

There are some critical aspects regarding the experimental validation of the results from bioinformatical SIM and AIM detection approaches. As already mentioned, the bioinformatical approach targets SIMs which have been evolved for efficient SUMO binding in the course of evolution. For experimental validation of SIMs and AIMS, however, the complete biological context has to be matched in the experimental conditions, with regard to all relevant binding partners, modifications etc. Experimental results from binding assays of a SIP against an isolated SUMO moiety or against an biologically irrelevant SUMOylated protein may give negative results. Proteins such as Rad18 bind distinct SUMOylated proteins via additional interaction between other parts of these proteins [Parker and Ulrich, 2012]. The SIP therefore is able to distinguish between SUMOylated proteins, with the SUMO binding being only one part of the overall interaction between proteins.

STUBs belong to another class of SUMO interacting proteins. They are proteins with several SIMs for binding of all kinds of polySUMOylated proteins. The additive use

5. Discussion

of SIMs allows SUMO chain recognition. The SUMOylated protein is not involved in the binding. The Slx5-Slx8 heterodimer in *Saccharomyces cerevisiae* is such a STUbL (section 1.3.4) [Wang et al., 2006]. This complex recognize high molecular weight SUMO conjugates via four SIMs (2 SIMa, 2 SIMb) [Uzunova et al., 2007, Mullen and Brill, 2008]. Experimental validations have therefore to be carefully designed. Their results have to be counter-checked by several methods.

A. Appendix: Motif list from the bioinformatical SIMa detection approach

Table A.1. List of SIMa instances from the bioinformatical SIMa detection approach. A SIMa profile search within a *Saccharomyces cerevisiae* protein sequence database with a sensitivity of $C = 3.2$ and further refinement by conservation criteria ($t_1 = 1.0$, $t_2 = 1.6$, $t_3 = 0.2$) gave this list of putative SIMa instances. Evaluation of results was performed according to a combined ‘bioinformatical motif score’. This score describes the profile adherence, conservation and structural context features of the instance.

B. Appendix: Motif list from the bioinformatical SIMb detection approach

Table B.1. List of SIMb instances from the bioinformatical SIMb detection approach. A SIMb profile search within a *Saccharomyces cerevisiae* protein sequence database with a sensitivity of $C = 4.0$ and further refinement by conservation criteria ($t1 = 1.2$, $t2 = 1.55$, $t3 = 1.0$) gave this list of putative SIMb instances. Evaluation of results was performed according to a combined 'bioinformatical motif score'. This score describes the profile adherence, the conservation and the structural context features of the instance.

For the SIMb bioinformatical detection approach, a more stringent criterion $t1 = 1.75$ was applied first, the weakened criterion $t1 = 1.2$ in a second screen. The results of both screens differ in one instance: The Tdp1 instance shows less conservation than the others in this list, affecting its overall 'bioinformatical score'.

D. Appendix: Motif list from the bioinformatical AIM detection approach

Table D.1. List of AIM instances from the bioinformatical AIM detection approach. A AIM profile search within a *Saccharomyces cerevisiae* protein sequence database with a sensitivity of $C = 3.0$ and further refinement by conservation criteria($t1 = 1.75$, $t2 = 1.55$, $t3 = 1.0$) gave this list of putative AIM instances. Evaluation of results was performed according to a combined ‘bioinformatical motif score’. This score describes the profile adherence, the conservation and the structural context features of the instance.

Acknowledgement

I want to thank Prof. Dr. Kay Hofmann for his excellent guidance and encouragements during this work. His enthusiasm and optimism helped me to keep focussed even in hard times. Especially, I want to thank him for teaching me the bioinformatical skills, providing the computational infrastructure, a wealth of databases and programming advice where needed for this thesis. Thank you for your endless advice during my writing period.

I also want to thank Prof. Dr. Jürgen Dohmen for academic supervision of this work and for having me as a part of his research team for the interaction studies. Thank you for your faith in me! I also want to thank you for your advices during my writing period.

I want to thank Dr. Hartmut Scheel in his encouragements and his personal friendship. Without him, I may have never believed in myself during all periods of this thesis. I never thought I will make it!

A big “Thank you” for the AG Hofmann and AG Dohmen people for being so open-hearted people! Thank you for giving me a good time with you!

I want to thank Dr. Shuhua Chen for “forcing me to keep on track”. She never allowed me to stop! Thank you so much for beeing my personal “Jiminy Cricket”. I also want to thank her for giving me so many critical advices during the writing process!

I want to thank Dr. Karsten Klopffleisch for his advices in experimental issues where necessary. And thank you for giving me also so many advice during this work.

I want to thank Ms. Jessica Buchmüller for so many advices. I want to thank Jessy and Karsten for making lab work always a pleasure!

I want to thank Dr. Marion Schnellhardt for teaching me crash courses in biological experiments.

Eidesstattliche Erklärung

Ich versichere, dass ich die von mir vorgelegte Dissertation selbständig angefertigt, die benutzten Quellen und Hilfsmittel vollständig angegeben und die Stellen der Arbeit — einschließlich Tabellen, Karten und Abbildungen —, die anderen Werken um Wortlaut oder Sinn nach entnommen sind, in jedem Einzelfall als Entlehnung kenntlich gemacht habe; dass diese Dissertation noch in keiner anderen Fakultät oder Universität zur Prüfung vorgelegen hat; dass sie — abgesehen von unten angegebenen Teilpublikationen — noch nicht veröffentlicht worden ist, sowie, dass ich eine solche Veröffentlichung vor Abschluss des Promotionsverfahrens nicht vornehmen werde.

Die Bestimmungen dieser Promotionsordnung sind mir bekannt. Die von mir vorgelegte Dissertation ist von Prof. Kay Hofmann betreut worden.

- Teilpublikationen liegen nicht vor
- Nachfolgend genannte Teilpublikationen liegen vor:

Benjamin Vogt and Kay Hofmann (2012). Bioinformatical detection of recognition factors for ubiquitin and SUMO. *Methods Mol. Biol.* 832, 249–261.

Tania M. Roberts, Benjamin Vogt, Edyta Siergiuk, Yiming Chang, Caroline Wilson-Zbinden, Vikram Panse, Kay Hofmann and Matthias Peter. Bioinformatic analysis identified the 60S ribosomal maturation factor Rei1 as a cargo adaptor for ribophagy in *Saccharomyces cerevisiae*, *Nat. Cell Biol.*, submitted.

Ich versichere, dass ich alle Angaben wahrheitsgemäß nach bestem Wissen und Gewissen gemacht habe, und verpflichte mich, jedmögliche, die obigen Angaben betreffenden Angaben dem Dekanat unverzüglich mitzuteilen.

Köln, den 29. April 2014

Benjamin Vogt

Persönliche Daten

Geburtsdatum: 20. September 1981
Geburtsort: Bonn-Duisdorf
Familienstand: ledig

Promotionsstudium

07.2009 – 04.2014
Anfertigung der Dissertation im Fach Genetik,
Titel: „A bioinformatical approach for a reliable determination of short motifs for SUMO and Atg8 interaction in *Saccharomyces cerevisiae*“,
Arbeitsgruppe Professor Dr. Kay Hofmann,
Institut für Genetik der Universität zu Köln

Hochschulstudium

10.2008 – 04.2009
Anfertigung der Diplomarbeit,
Titel: „Synthese und Charakterisierung eines Inhibitors der Dihydroceramid-Desaturase“,
Arbeitsgruppe Professor Dr. Konrad Sandhoff,
Kekulé-Institut für organische Chemie und Biochemie der Rheinischen Friedrich Wilhelms-Universität zu Bonn
Diplom (Note: gut)

04.2002 – 04.2009
Diplom-Studiengang (Fachrichtung: Chemie),
Rheinische Friedrich Wilhelms-Universität zu Bonn
Diplom-Vorprüfung (Note: gut)

Schulbildung

08.1992 – 06.2001
Gymnasium Marienschule, Euskirchen
Abitur (Note: 2,2)

09.1989 – 07.1992
Grundschule Franziskusschule, Euskirchen

Zivildienst

08.2001 – 04.2002
Verein für Vormundschaften und Betreuungen,
Diakonisches Werk, Euskirchen
