ABSTRACT

Accurate rotation–vibration line lists for two molecules, NaCl and KCl, in their ground electronic states are presented. These line lists are suitable for temperatures relevant to exoplanetary atmospheres and cool stars (up to 3000 K). Isotopologues $^{23}\text{Na}^{35}\text{Cl}$, $^{23}\text{Na}^{37}\text{Cl}$, $^{39}\text{K}^{35}\text{Cl}$, $^{39}\text{K}^{37}\text{Cl}$, $^{41}\text{K}^{35}\text{Cl}$ and $^{41}\text{K}^{37}\text{Cl}$ are considered. Laboratory data were used to refine ab initio potential energy curves in order to compute accurate ro-vibrational energy levels. Einstein A coefficients are generated using newly determined ab initio dipole moment curves calculated using the CCSD(T) method. New Dunham Y_{ij} constants for KCl are generated by a re-analysis of a published Fourier transform infrared emission spectra. Partition functions plus full line lists of ro-vibration transitions are made available in an electronic form as supplementary data to this paper and at www.exomol.com.

Key words: molecular data – opacity – astronomical data bases: miscellaneous – planets and satellites: atmospheres – stars: low-mass.

1 INTRODUCTION

NaCl and KCl are important astrophysical species as they are simple, stable molecules containing atoms of relatively high cosmic abundance. Na, K and Cl are the 15th, 20th and 19th most abundant elements in the interstellar medium (Caris et al. 2004). In fact, NaCl could be as abundant as the widely observed SiO molecule (Cernicharo & Guelin 1987). Cernicharo & Guelin (1987) reported the first detection of metal halides, NaCl, KCl, AlCl and, more tentatively, AlF, in the circumstellar envelope of carbon star IRC+10216. These observations have been followed up recently by Agundez et al. (2012), who also observed CS, SiO, SiS and NaCN. NaCl has also been detected in the circumstellar envelopes of oxygen stars IK Tauri and VY Caris Majoris (Milam et al. 2007). Another environment in which these molecules have been found is the tenuous atmosphere of Jupiter’s moon Io. Submillimetre lines of NaCl, and more tentatively KCl, were detected by Lellouch et al. (2003) and Moullet et al. (2013), respectively. NaCl has also been identified in the cryovolcanic plumes of Saturn’s moon Enceladus alongside its constituents Na and Cl (Postberg et al. 2011). K was also detected but the presence of KCl could not be confirmed. Furthermore, NaCl and KCl are expected to be present in super-Earth atmospheres (Schaefer, Lodders & Fegley 2012) and may form in the observable atmosphere of the known object GJ1214b (Kreidberg et al. 2014).

The alkali chlorides are also of industrial importance as they are products of coal and straw combustion. Their presence in coal

increases the rate of corrosion in coal-fired power plants (Yang et al. 2014). Therefore, it is important to monitor their concentrations, which can be done spectroscopically provided the appropriate data are available.

The importance of NaCl and KCl spectra has motivated a number of laboratory studies, for example Rice & Klemperer (1957), Honig et al. (1954), Horiai et al. (1988), Uehara et al. (1989, 1990) and Clouser & Gordy (1964). The most recent and extensive research on KCl and NaCl spectra has been performed by Ram et al. (1997), who investigated infrared emission lines of Na^{35}Cl , Na^{37}Cl and $^{39}\text{K}^{35}\text{Cl}$, Caris et al. (2004), who measured microwave and millimetre wave lines of $^{39}\text{K}^{35}\text{Cl}$, $^{39}\text{K}^{37}\text{Cl}$, $^{41}\text{K}^{35}\text{Cl}$, $^{41}\text{K}^{37}\text{Cl}$ and $^{40}\text{K}^{35}\text{Cl}$, and Caris, Lewen & Winnewisser (2002), who recorded microwave and millimetre wave lines of Na^{35}Cl and Na^{37}Cl .

Dipole moment measurements have been carried out by Leeuw, Wachem & Dymanus (1970) for Na^{35}Cl and Na^{37}Cl , Wachem & Dymanus (1967) for $^{39}\text{K}^{35}\text{Cl}$ and $^{39}\text{K}^{37}\text{Cl}$, and Hebert et al. (1968) for $^{39}\text{K}^{35}\text{Cl}$, Na^{35}Cl and Na^{37}Cl .

It appears that the only theoretical transition line lists for these molecules are catalogued in the Cologne Database for Molecular Spectroscopy (CDMS; see Muller et al. 2005). They were constructed using data reported in Caris et al. (2002), Clouser & Gordy (1964), Uehara et al. (1989) and Leeuw et al. (1970) for NaCl, and Caris et al. (2004), Clouser & Gordy (1964) and Wachem & Dymanus (1967) for KCl. The lists are limited to $v = 4$, $J = 159$ and do not include a list for $^{41}\text{K}^{37}\text{Cl}$. In this paper, we aim to compute more comprehensive line lists for the previously studied isotopologues and the first theoretical line list for $^{41}\text{K}^{37}\text{Cl}$.

The ExoMol project aims to provide line lists for all the molecular transitions of importance in the atmospheres of exoplanets. The aims, scope and methodology of the project have been summarized by Tennyson & Yurchenko (2012). Lines lists for $X^2\Sigma^+$ XH molecules, $X = \text{Be}, \text{Mg}, \text{Ca}$, and $X^1\Sigma^+$ SiO have already been published (Yadin et al. 2012; Barton, Yurchenko & Tennyson 2013, respectively). In this paper, we present ro-vibrational transition lists and associated spectra for two NaCl and four KCl isotopologues.

2 METHOD

The nuclear motion Schrödinger equation allowing for Born–Oppenheimer breakdown (BOB) effects is solved for species XCl using the program LEVEL (Le Roy 2007). To initiate these calculations, the program DPOTFIT (Le Roy 2006) was used to generate a refined potential energy curve (PEC) for each molecule by fitting analytic PEC functions derived from ab initio points to laboratory data.

2.1 Spectroscopic data

The most comprehensive and accurate sets of available laboratory measurements are the infrared ro-vibrational emission lines of Ram et al. (1997) and the microwave rotational lines of Caris et al. (2002) and Caris et al. (2004) all of which were recorded at temperatures in the region of 1000 C, see Table 1. No electronic transition data appear to be available. For KCl Fourier transform, infrared emission spectra measured by Ram et al. (1997) have been re-analysed and re-assigned as part of this work, see Section 2.2. The Dunham constants (Y_{ij}) obtained from this new fit are provided in Table 2. Our new assignments for the ro-vibrational emission lines were used in place of those given by Ram et al. (1997).

2.2 Re-analysis of the KCl infrared spectrum

Ram et al. (1997) reported spectroscopic constants derived from an infrared emission spectrum of KCl recorded with a high-resolution Fourier transform spectrometer (FTS). By using the new constants derived from the millimetre wave spectrum by Caris et al. (2004)

to simulate the infrared spectrum of $^{39}\text{K}^{35}\text{Cl}$ with PGOPHER (Western 2013), it was clear that Ram et al. (1997) had misassigned much of the complex spectrum. The Ram et al. (1997) spectrum was therefore re-analysed. As a first step, the millimetre wave line list from Caris et al. (2004) was refitted with the addition of two Dunham parameters, Y_{23} and Y_{41} . These parameters were found to improve the quality of the fit. The Caris et al. (2004) constants plus Y_{23} and Y_{41} were then used to calculate band constants used as input for PGOPHER. Using PGOPHER, the infrared line positions were selected manually and then refitted along with the Caris data using our LSQ fit program. There were 253 R-branch lines of $^{39}\text{K}^{35}\text{Cl}$ fit from the 6–5, 5–4, 4–3, 3–2, 2–1 and 1–0 bands, and the Y_{10} , Y_{20} and Y_{30} vibrational constants were added. The quality of the observed spectrum was insufficient to fit additional bands or P-branch lines. The final constants from our global fit are compared to the values reported by Caris et al. (2004) in Table 2. The Y_{10} and Y_{20} (ω_e and $-\omega_e x_e$) constants of Caris et al. (2004) were derived entirely from millimetre wave data using Dunham relationships and are in good agreement with the values we have determined directly from infrared observations.

2.3 Dipole moments

Experimental measurements of the permanent dipole as a function of the vibrational state have been performed by Leeuw et al. (1970), Wachem & Dymanus (1967) and Hebert et al. (1968), who considered NaCl, KCl and both molecules, respectively. Additionally, Pluta (2001) calculated dipole moments at equilibrium bond length as part of theoretical study comparing various levels of theory [SCF, MP2, CCSD and CCSD(T)]. Giese & York (2004) computed NaCl dipole moment curves (DMCs) using a multireference configuration interaction approach and extrapolated basis sets. However, there appear to be no published KCl DMCs, experimental or ab initio.

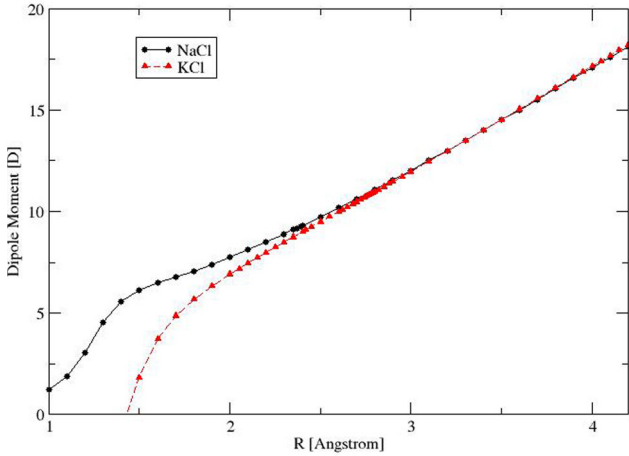

Figure 1. Ab initio DMCs for NaCl and KCl in their ground electronic states.

We determined new DMCs for both molecules using high-level ab initio calculations, shown in Fig. 1. These were performed using MOLPRO (Werner et al. 2010). The points defining the new dipole moment functions are given in Tables 3 and 4. The final NaCl DMC was computed using an aug-cc-pCVQZ-DK basis set and the CCSD(T) method, where both core-valence and relativistic effects were also taken into account. Inclusion of both effects is known to be important (Tennyson 2014). In the case of KCl, an effective core potential ECP10MDF (MCDHF+Breit) in conjunction with the corresponding basis set (Lim et al. 2005) was used for K and aug-cc-pV(Q+d)Z was used for Cl. In both cases, the electric dipole moments were obtained using the finite field method. The ab initio DMC grid points were used directly in LEVEL. Equilibrium bond length dipole moments are compared in Table 5. Our computed equilibrium dipole for KCl is about 1 per cent larger than the experimental value. For NaCl, this difference is closer to 2 per cent but our final CCSD(T) value is close to those calculated by Giese & York (2004).

2.4 Fitting the potentials

The PECs were refined by fitting to the spectroscopic data identified in Table 1. However, extending the temperature range of the spectra requires consideration of highly excited levels and extrapolation of the PECs beyond the region determined by experimental input values; hence, care needs to be taken to ensure that the curves maintain physical shapes outside the experimentally refined regions. In this context, we define a physical shape to be the shape of the ab initio curve. We tested multiple potential energy forms, namely the extended Morse oscillator (EMO), Morse long range (MLR) and Morse–Lennard Jones potentials (Le Roy 2011), to achieve an optimum fit to the experimental data whilst maintaining a physical curve shape. Data for multiple isotopologues were fitted simultaneously to ensure that the resulting curves are valid for all isotopologues. r_e and D_e were held constant in the fits, as the fits were found to be unstable otherwise.

For NaCl, BOB terms did not improve the quality of the fit and were not pursued. Of the 1370 lines used in the fit, 1060 were Na³⁵Cl and 310 were Na³⁷Cl. The final potential was expressed as an EMO:

$$V_{\text{EMO}}(r) = D_e [1 - e^{-\beta(r)(r-r_e)}]^2, \quad (1)$$

where

$$\beta(r) = \beta_{\text{EMO}}(y_p^{\text{eq}}(r)) = \sum_{i=0}^{N_\beta} \beta_i y_p^{\text{eq}}(r)^i, \quad (2)$$

$$y_p^{\text{eq}}(r) = \frac{r^p - r_e^p}{r^p + r_e^p} \quad (3)$$

and p was set to 3, N to 4, D_e to 34 120.0 cm⁻¹ (Huber & Herzberg 1979) and r_e to 2.360 796 042 Å (Ram et al. 1997). Parameters resulting from the fit are given in Table 6.

For KCl potassium, centrifugal non-adiabatic BOB terms were included in the fit as they resulted in a reduction by up to 50 per cent, in the residuals (obs–calc) obtained for high J 's. Of the 549 lines used in the fit, 361 were ³⁹K³⁵Cl, 82 were ³⁹K³⁷Cl, 64 were ⁴¹K³⁵Cl and 40 were ⁴¹K³⁷Cl. The final potential was expressed as an MLR:

$$V_{\text{MLR}}(r) = D_e \left[1 - \frac{u_{\text{LR}}(r)}{u_{\text{LR}}(r_e)} e^{-\beta(r)y_p^{\text{eq}}(r)} \right]^2, \quad (4)$$

where

$$\beta(r) = \beta_{\text{MLR}}(y_p^{\text{eq}}(r)) = y_p^{\text{eq}}(r)\beta_\infty + [1 - y_p^{\text{eq}}(r)] \sum_{i=0}^{N_\beta} \beta_i y_p^{\text{eq}}(r)^i, \quad (5)$$

Table 6. Fitting parameters used in the NaCl EMO potential, see equation (1). (Uncertainties are given in parentheses in units of the last digit.)

N	β_i
0	0.894 7078(17)
1	−0.287 528(48)
2	0.005 81(11)
3	−0.0278(14)
4	−0.0290(37)

Table 7. Fitting parameters used in the KCl MLR potential, see equation (4). (Uncertainties are given in parentheses in units of the last digit.)

N	β_i	t_j
0	−0.907 5210(10)	0.0
1	1.235 90(85)	0.00 30(12)
2	0.4859(22)	0.0
3	1.200(10)	0.0

$$y_p^{\text{eq}}(r) = \frac{r^p - r_e^p}{r^p + r_e^p} \quad (6)$$

$$u_{\text{LR}}(r) = \frac{C_m}{r^m} + \frac{C_n}{r^n} \quad (7)$$

and p was set to 2, N to 3, m to 2, n to 3, C_2 to 10 000, C_3 to 13 000 000, D_e to 34 843.15 cm⁻¹ (Brewer & Brackett 1961) and r_e to 2.666 725 3989 Å (Caris et al. 2004). Constants C_2 and C_3 were implemented because the use of conventional constants C_6 and C_8 resulted in poor or no convergence giving completely non-physical curves.

The centrifugal non-adiabatic BOB correction function is defined as

$$g(r) = \frac{M_{\text{ref}}}{M} \left[y_{p_{\text{na}}}^{\text{eq}}(r)t_\infty + [1 - y_{p_{\text{na}}}^{\text{eq}}(r)] \sum_{j=0}^N t_j [y_{p_{\text{na}}}^{\text{eq}}(r)]^j \right], \quad (8)$$

where

$$y_{p_{\text{na}}}^{\text{eq}}(r) = \frac{r^{p_{\text{na}}} - r_e^{p_{\text{na}}}}{r^{p_{\text{na}}} + r_e^{p_{\text{na}}}} \quad (9)$$

and M is the total mass of the particular isotopologue, M_{ref} is the total mass of the parent isotopologue, p_{na} was set to 2 and N to 1. Parameters resulting from this fit are given in Table 7.

The input experimental data were reproduced within 0.01 cm⁻¹ and often much better than this. The final curves, shown in Fig 2, follow the ab initio shape with the exception of regions 6–17 Å for KCl and 4.5–8 Å for NaCl. These regions are associated with the textbook avoided crossings between Columbic $X^+ - \text{Cl}^-$ and neutral $X - \text{Cl}$ PECs which occur in the adiabatic representation of the ground electronic state, see Giese & York (2004) for a detailed discussion. Without experimental data near dissociation, it is difficult to represent this accurately with DPOTFIT. Consequently, we decided to limit our line lists to vibrational states lying below 20 000 cm⁻¹ which do not sample these regions. This has consequences for the temperature range considered. Based on our partition sum, see Section 2.5, this range is 0–3000 K.

Comparisons with observed frequencies for Na³⁵Cl and ³⁹K³⁵Cl are given in Tables 8 and 9. These demonstrate the accuracy of our fits. An important aim in refining a PEC is to also predict spectroscopic data outside the experimental range. This can be tested for KCl for which there are R -band head measurements up to $v = 12$ (Ram et al. 1997). The positions of these band heads, which are key features in any weak or low-resolution spectrum, are predicted to high accuracy, see Table 10.

2.5 Partition functions

The calculated energy levels, see Section 3, were summed in Excel to generate partition function values for a range of temperatures.

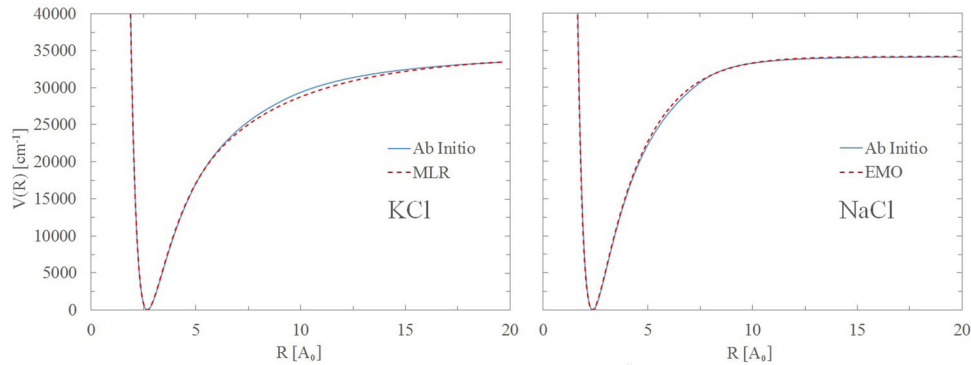

Figure 2. Comparison of ab initio and fitted ground electronic state PECs for NaCl (right) and KCl (left).

We determined that our partition function is at least 95 per cent converged at 3000 K and much better than this at lower temperatures. Therefore, temperatures up to 3000 K were considered. Values for the parent isotopologues are compared to previous studies, namely Irwin (1981), Sauval & Tatum (1984) and CDMS, in Table 11.

For ease of use, we fitted our partition functions, Q , to a series expansion of the form used by Vidler & Tennyson (2000):

$$\log_{10} Q(T) = \sum_{n=0}^6 a_n [\log_{10} T]^n \quad (10)$$

with the values given in Table 12.

2.6 Line-list calculations

While sodium has only a single stable isotope, ^{23}Na , both potassium and chlorine each have two: ^{39}K (whose natural terrestrial

abundance is about 93.25 per cent) and ⁴¹K (6.73 per cent), and ³⁵Cl (75.76 per cent) and ³⁷Cl (24.24 per cent). Line lists were therefore calculated for two NaCl and four KCl isotopologues. Rotational states up to $v = 100$, $J = 563$ and $v = 120$, $J = 500$, respectively, and all transitions between these states satisfying the dipole selection rule $\Delta J = \pm 1$, were considered. A summary of each line list is given in Table 13.

The procedure described above was used to produce line lists, i.e. catalogues of transition frequencies ν_{ij} and Einstein coefficients A_{ij}

for two NaCl and four KCl isotopologues: Na³⁵Cl, Na³⁷Cl, ³⁹K³⁵Cl, ³⁹K³⁷Cl, ⁴¹K³⁵Cl and ⁴¹K³⁷Cl. The computed line lists are available in electronic form as supplementary information to this paper.

3 RESULTS

The full line list computed for all isotopologue considered is summarized in Table 13. Each line list contains around 4 million

transitions for NaCl and 7 million for the heavier KCl isotopologues; each line list is therefore, for compactness and ease of use, divided into a separate energy file and transition file. This is done using the standard ExoMol format (Tennyson, Hill & Yurchenko 2013) which is based on a method originally developed for the BT2 line list (Barber et al. 2006). Extracts from the start of the Na³⁵Cl and ³⁹K³⁵Cl files are given in Tables 14–17. They can be downloaded from the CDS via <http://cdsweb.u-strasbg.fr/cgi-bin/qcat?J/MNRAS/>. The line lists and partition functions can also be obtained from www.exomol.com.

Fig. 3 illustrates the synthetic absorption spectra of Na³⁵Cl and ³⁹K³⁵Cl at 300 K. As the DMCs are essentially straight lines, the overtone bands for these molecules are very weak meaning that key spectral features are confined to long wavelengths associated with the pure rotational spectrum and the vibrational fundamental.

The CDMS data base contains 607 and 772 rotational lines for Na³⁵Cl and ³⁹K³⁵Cl, respectively. Comparisons with the CDMS lines are presented in Fig. 4. As can be seen, the agreement is excellent for both frequency and intensity. In particular, predicted line intensities agree within 2 and 4 per cent for the KCl and NaCl isotopomers considered in CDMS, respectively.

Emission cross-sections for Na³⁵Cl and ³⁹K³⁵Cl were simulated using Gaussian line-shape profiles with half-width = 0.01 cm⁻¹ as described by Hill, Yurchenko & Tennyson (2013). The resulting synthetic emission spectra are compared to the experimental ones in Figs 5 and 6. When making comparisons, one has to be aware of a number of experimental issues. The baseline in NaCl shows residual ‘channelling’: a sine-like baseline that often appears in FTS

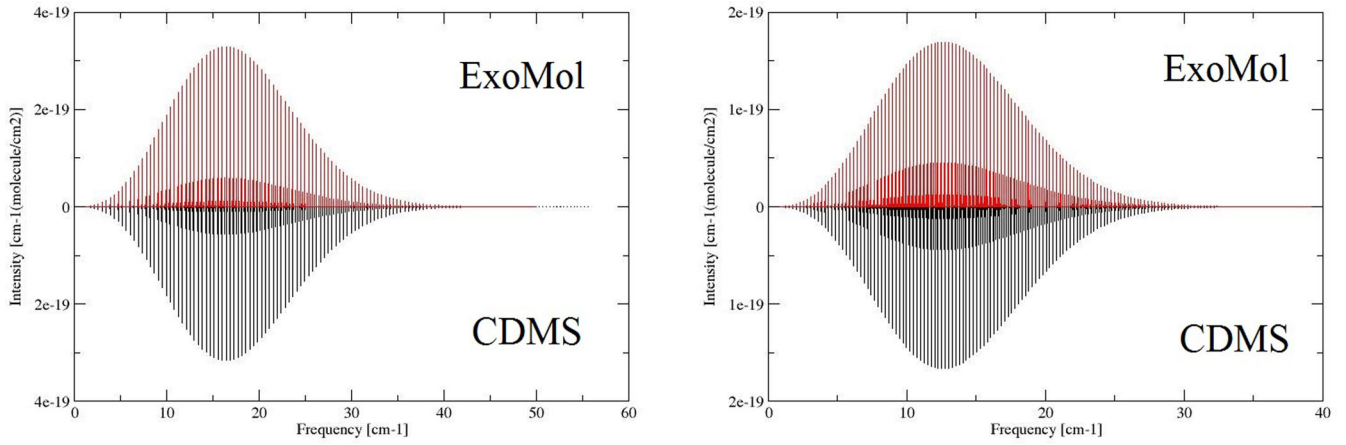

Figure 4. Absorption lines of Na^{35}Cl and $^{39}\text{K}^{35}\text{Cl}$ at 300 K: ExoMol versus CDMS.

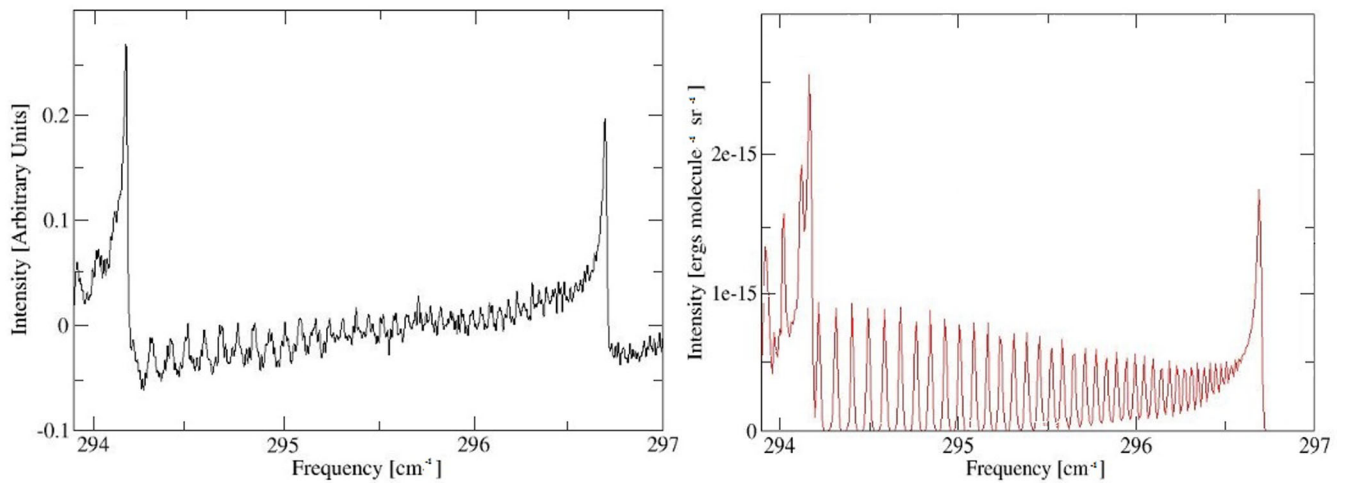

Figure 6. Emission spectra of KCl at 1273 K: left, Ram et al. (1997); right, ExoMol.

spectra due to interference from reflections from parallel optical surfaces in the beam. For KCl, the spectrum is very weak and the baseline, which has a large offset, was not properly adjusted to zero. Given these considerations, the comparisons must be regarded as satisfactory.

4 CONCLUSIONS

We present accurate but comprehensive line lists for the stable isotopologues of NaCl and KCl. Laboratory frequencies are reproduced to much more than sub-wavenumber accuracy. This accuracy should extend to all predicted transition frequencies up to at least $v = 8$ and 12 for NaCl and KCl, respectively. New ab initio dipole moments and Einstein A coefficients are computed. Comparisons with the semi-empirical CDMS data base suggest that the pure rotational intensities are accurate.

The results are line lists for the rotation–vibration transitions within the ground states of Na^{35}Cl , Na^{37}Cl , $^{39}\text{K}^{35}\text{Cl}$, $^{39}\text{K}^{37}\text{Cl}$, $^{41}\text{K}^{35}\text{Cl}$ and $^{41}\text{K}^{37}\text{Cl}$, which should be accurate for a range of temperatures up to at least 3000 K. The line lists can be downloaded from the CDS or from www.exomol.com.

Finally, we note that HCl is likely to be the other main chlorine-bearing species in exoplanets. Comprehensive line lists for H^{35}Cl and H^{37}Cl have recently been provided by Li et al. (2013a,b).

ACKNOWLEDGEMENTS

We thank Alexander Fateev for stimulating discussions and Kevin Kindley for some preliminary work with the KCl infrared emission spectrum. This work was supported by grant from energinet.dk under a subcontract from the Danish Technical University and by the ERC under the Advanced Investigator Project 267219. Support was also provided by the NASA Origins of Solar Systems programme.
