**Abstract.** We present a numerical model for time domain reflectometry (TDR) signal propagation in dispersive dielectric materials. The numerical probe model is terminated with a parallel circuit, consisting of an ohmic resistor and an ideal capacitance. We derive analytical approximations for the capacitance, the inductance and the conductance of three-wire probes. We couple the time domain model with global optimization in order to reconstruct water content profiles from TDR traces. For efficiently solving the inverse problem we use genetic algorithms combined with a hierarchical parameterization. We investigate the performance of the method by reconstructing synthetically generated profiles. The algorithm is then applied to retrieve dielectric profiles from TDR traces measured in the field. We succeed in reconstructing dielectric and ohmic profiles where conventional methods, based on travel time extraction, fail.

et al., 1999; Oswald, 2000; Oswald et al., 2003; Lin, 2003; Heimovaara et al., 2004; Schlaeger, 2005).

Because the dielectric permittivity of soil material typically depends considerably on frequency, particularly if there are clay and loam components (Hoekstra and Delaney, 1974; Sposito and Prost, 1982; Ishida et al., 2000; Huisman et al., 2004; Robinson et al., 2005), in a third phase methods have been studied to recover the average dispersive dielectric parameters from TDR traces (Heimovaara, 1994; Heimovaara et al., 1996; Hilhorst et al., 2001; Lin, 2003). Clearly, the next logical step are methods to extract the full dielectric profile from a TDR trace.

## 1.2 Objectives

In this paper we study an efficient method for the reconstruction of spatially resolved profiles of water content and electrical conductivity from TDR traces assuming dispersive dielectric properties of the soil material along the probe. In particular, we want to reconstruct field measured TDR traces (Wollschläger and Roth, 2005) which could not be successfully reconstructed with techniques used by Roth et al. (1990).

We use the Debye model to account for dispersive dielectric properties (Debye, 1929). While the three-rod probe is often employed for TDR measurements, there is only scarce material on its transmission line parameters, particularly inductance, capacitance and conductance per unit length. We therefore derive an analytical model for these parameters under the approximation of small conductor diameter  $D$  with respect to conductors' center distance  $d$ . We assess the accuracy of the analytical model by comparing its predictions to a full-wave numerical analysis, using an established, commercially available program.

## 1 Introduction

### 1.1 Motivation

Time Domain Reflectometry (TDR) has become an indispensable technique for measuring the water content of soils in hydrology, civil engineering, agriculture and related fields over the last years, for a review see Robinson et al. (2003). Early realizations of the method delivered a single water content  $\theta$  from a TDR trace (Birchak et al., 1974; Topp et al., 1980, 1982a,b; Topp and Davis, 1985; Dasberg and Dalton, 1985). A second phase of TDR development has targeted to deliver spatially resolved water content profiles along the TDR probe (Yanuka et al., 1988; Hook et al., 1992; Dasberg and Hopmans, 1992; Lundstedt and Ström, 1996; Norgren and He, 1996; Pereira, 1997; Todoroff et al., 1998; Feng

## 2 Methods

The propagation of TDR signals, voltage  $v(x, t)$  and current  $i(x, t)$ , on probes of two or more conducting rods is described by transmission line theory (e.g. Ramo et al., 1984). Our approach for numerically modeling TDR probes is essentially based on Oswald et al. (2003). A transmission line is described by capacitance  $C'$ , conductance  $G'$ , inductance  $L'$  and resistance  $R'$ , all per unit length, respectively. These parameters are functions of the probe geometry and the dielectric and ohmic properties of the material between the probe's conductors  $C'=C'(d, D, \epsilon)$ ,  $G'=G'(d, D, \sigma)$ ,  $L'=L'(d, D, \mu)$  and  $R'=R'(d, D, R_{\text{skin}})$  where  $d$  is the spacing between the probe rods (for a three rod probe this is the distance between neighboring rods) and  $D$  is the diameter of the probe rods. We assume rods of identical diameter.

For piecewise constant transmission line parameters, voltage  $v(x, t)$  and current  $i(x, t)$  are described by the following two linear first order, partial differential equations (PDE) (Ramo et al., 1984):

$$\frac{\partial v}{\partial x} = - \left( R' + L' \frac{\partial}{\partial t} \right) i \quad (1)$$

$$\frac{\partial i}{\partial x} = - \left( G' + C' \frac{\partial}{\partial t} \right) v. \quad (2)$$

The piecewise constant dielectric permittivity  $\epsilon$  and ohmic conductivity  $\sigma$  can be discontinuous, because the water content  $\theta$  in general is discontinuous across soil boundaries. With a variable water content  $\theta(x)$  along the probe the parameters  $G'$  and  $C'$  vary accordingly;  $L'$  is assumed to be constant, because the materials' magnetic permeability equals  $\mu_0$ ; resistance  $R'$ , caused by skin effect, is neglected in the current study.

For extracting dielectric and ohmic profiles from measured TDR traces we use an iterative, globally optimizing approach based on Oswald et al. (2003) in order to solve the non-linear, inverse, electromagnetic problem. The global optimization method uses genetic algorithms (GA) from a publicly available library Levine (1996).

To calculate the TDR signal for a given dielectric profile we numerically solve Eqs. (1) and (2) using a finite difference time domain (FDTD) approach (Taflove, 1998). The spatial discretization of the  $x$  coordinate is given by  $x=k\Delta x$  and temporal discretization by  $t=n\Delta t$  with:

$$\Delta x \leq \frac{\lambda_{\min}}{10} \quad (3)$$

where  $\lambda_{\min}$  is the minimum wavelength present in the system, which in non-magnetic material, is determined by the maximum frequency  $f_{\max}$  and the largest permittivity value  $\epsilon_{\max}$  (Taflove, 1998):

$$\lambda_{\min} = \frac{c_0}{f_{\max} \sqrt{\epsilon_{r,\max}}}. \quad (4)$$

We estimate the maximum relevant frequency from

$$t_{\text{rise}} \cdot f_{3\text{dB}} = 0.34, \quad (5)$$

an expression widely used in electrical engineering. It refers to a Gaussian type time domain waveform with rise time  $t_{\text{rise}}$ . This is a good model for a TDR input signal.

To keep the explicit time domain integration scheme stable, an upper limit for  $\Delta t$  must be observed (Taflove, 1998; Kunz and Luebbers, 1993):

$$\Delta t \leq \frac{\Delta x}{c_0} \quad (6)$$

### 2.1 Numerical solution of transmission line equations

Numerically, there are three spatially different regions, at the beginning of the probe  $x=0$ , at the end of the probe,  $x=\Lambda$ , and in-between,  $x<0<\Lambda$ . At the ends of the probe, the discretized set of PDE is connected to a lumped electrical model, such as voltage sources or resistive-capacitive terminations.

#### 2.1.1 Boundary conditions

The termination of a TDR probe is modeled with a parallel circuit, consisting of an ohmic resistor and an ideal capacitance. The voltage current relationship of this parallel circuit is given by

$$I_T = \frac{V_T}{R_T} + C_T \frac{\partial V_T}{\partial t} \quad (7)$$

where  $I_T$  is the current at the end of the TDR probe through the terminal resistor  $R_T$  and the terminal capacitance  $C_T$ .  $V_T$  is the voltage drop at the end of the TDR probe over the parallel circuit of  $R_T$  and  $C_T$ . To couple this parallel circuit to the distributed transmission line model we use Eq. (1). We truncate the FDTD scheme of the probe through coupling Eqs. (1) and (7) using the definitions:

$$i(x = \Lambda, t) = I_T \quad (8)$$

$$v(x = \Lambda, t) = V_T. \quad (9)$$

We rewrite Eq. (1)

$$\frac{\partial v}{\partial x} = -R'_k i - L'_k \frac{\partial i}{\partial t} \Big|_{x=\Lambda} \quad (10)$$

$$\Rightarrow \frac{\partial}{\partial x} v(x = \Lambda, t) = -R'_K i(\Lambda, t) - L'_K \frac{\partial}{\partial t} i(\Lambda, t). \quad (11)$$

All current terms in Eq. (11) are replaced by inserting Eq. (7). Note that the currents in the expressions, both constitutive and first-order PDE, are equivalent. Also, the voltages at the end of the probe and across the resistor are equal:

$$\begin{aligned} \frac{\partial}{\partial x} v(\Lambda, t) &= -\frac{R'_K}{R_T} v(\Lambda, t) - R'_K C_T \frac{\partial}{\partial t} v(\Lambda, t) \\ &\quad - \frac{L'_K}{R_T} \frac{\partial}{\partial t} v(\Lambda, t) - L'_K C_T \frac{\partial^2}{\partial t^2} v(\Lambda, t). \end{aligned} \quad (12)$$

We select a suitable discretization of Eq. (12): (i) the discretization must result in a fully explicit update scheme; (ii) the scheme must not require values outside the spatial computational domain  $x=[0 \dots \Lambda]$ . We choose the “backward differencing in space” and “forward differencing in time” scheme using the Taylor series expansion of first-order accuracy. The sum of backward and forward second-order Taylor series expansion in time provides the second order time derivative. With the usual notation we write the discretized version of Eq. (12):

$$\begin{aligned} \left( \frac{v_K^n - v_{K-1}^n}{\Delta x} \right) = & -\frac{R'_K}{R_T} v_K^n - R'_K C_T \left( \frac{v_K^{n+1} - v_K^n}{\Delta t} \right) \\ & -\frac{L'_K}{R_T} \left( \frac{v_K^{n+1} - v_K^n}{\Delta t} \right) \\ & -L'_K C_T \left( \frac{v_K^{n+1} - 2v_K^n + v_K^{n-1}}{\Delta t^2} \right). \end{aligned} \quad (13)$$

Finally, by rearranging Eq. (13) we obtain the explicit update procedure, in the time domain, for the voltage at the end of the TDR probe  $x=\Lambda$ .

$$\begin{aligned} v_K^{n+1} = & \left( \frac{R'_K C_T}{\Delta t} + \frac{L'_K}{R_T \Delta t} + \frac{L'_K C_T}{\Delta t^2} \right)^{-1} \\ & \cdot \left[ v_K^n \left( \frac{2L'_K C_T}{\Delta t^2} + \frac{L'_K}{R_T \Delta t} + \frac{R'_K C_T}{\Delta t} - \frac{R'_K}{R_T} \right. \right. \\ & \left. \left. - \frac{1}{\Delta x} \right) - \frac{L'_K C_T}{\Delta t^2} v_K^{n-1} + \frac{1}{\Delta x} v_{K-1}^n \right] \end{aligned} \quad (14)$$

and similarly for the current at  $x=\Lambda$  from, using Eq. (7):

$$i_K^{n+1} = \frac{1}{R_T} v_K^{n+1} + C_T \frac{v_K^{n+1} - v_K^n}{\Delta t}. \quad (15)$$

As special cases we mention  $C_T=0$ ,  $R_T<\infty$  and  $C_T=0$ ,  $R_T\rightarrow\infty$ . An overview of the equations of all these boundary conditions is given in Table 1. We have implemented them in our TDR code, so almost any given experimental setup can be modeled. The values of  $C_T$  and  $R_T$  can also be optimized for, if so desired.

To implement the excitation we employ the same approach used by Oswald et al. (2003). We couple a resistive voltage source to the distributed transmission line. The resistive voltage source consists of a series of an ideal ohmic resistor  $R_S$  and an ideal voltage source  $v_S^n$ . To avoid reflections between the voltage source and the cable connecting the TDR instrument to the probe we adjust  $R_S$  to the impedance of the connecting cable. The current flow out of the resistive voltage source is  $i_S^n$ . The time derivative of the source voltage is implemented with a discretized version of the given expression for the time domain signal shape.

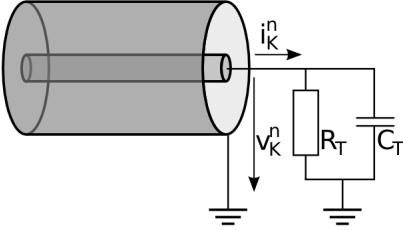

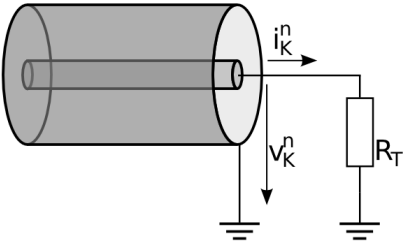

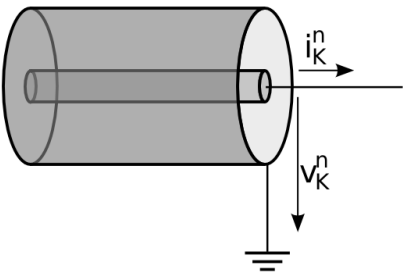

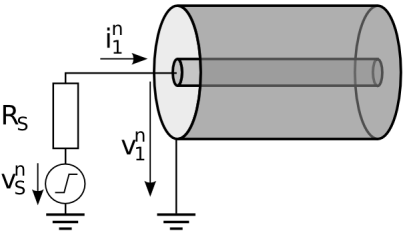

Fig. 1. Three-rod probe configuration and parameters.

### 2.1.2 Transmission line parameters for three-rod TDR probe

To solve the forward TDR problem the transmission line parameters for the three-rod probe,  $C'$ ,  $G'$ ,  $L'$  and  $R'$ , are essential. Closed-form, analytical expressions for the two-rod probe and the coaxial line are well known (Ramo et al., 1984). This is however not the case for the three-rod probe. We will derive an analytical model for the three-rod TDR probe based on an approximation of the electric and magnetic fields. The resulting transmission line parameters are compared to numerical simulations.

We calculate the electric parameters,  $C'$  and  $G'$ , from the electric potential  $\Phi_{el}$  and the inductance  $L'$  from the magnetic induction  $\mathbf{B}$  of the three-rod probe. For long rods and a large conductor distance  $d$  in comparison to the conductor diameter  $D$ , i.e.  $\frac{D}{d} \ll 1$ , we approximate the electric potential and the magnetic induction. We postulate that the total electrostatic potential of a three-rod probe equals the superposition of the single conductor potentials; the same assumption applies for the magnetic induction. Thus, the neighboring conductors are neglected for the derivation of the potential of

**Table 1.** Summary of boundary conditions.

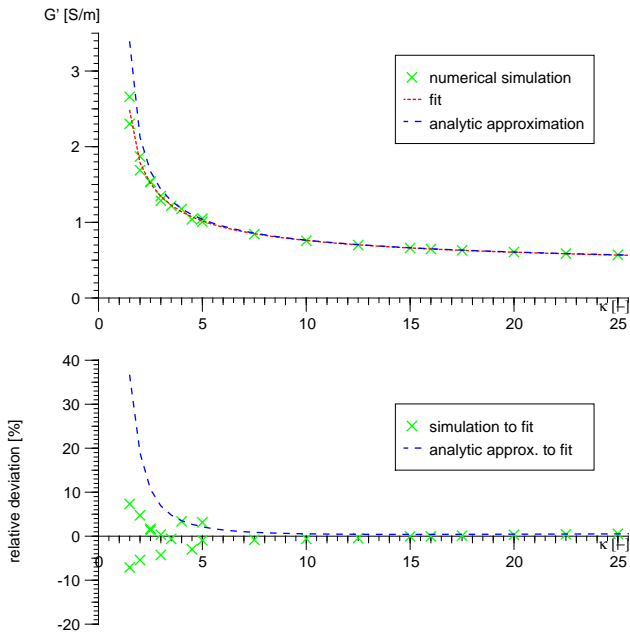

termination condition	voltage	current
parallel resistive capacitive termination 	$v_K^{n+1} = \left( \frac{R'_K C_T}{\Delta t} + \frac{L'_K}{R_T \Delta t} + \frac{L'_K C_T}{\Delta t^2} \right)^{-1} \cdot \left[ v_K^n \left( \frac{2L'_K C_T}{\Delta t^2} + \frac{L'_K}{R_T \Delta t} + \frac{R'_K C_T}{\Delta t} - \frac{R'_K}{R_T} - \frac{1}{\Delta x} \right) - \frac{L'_K C_T}{\Delta t^2} v_K^{n-1} + \frac{1}{\Delta x} v_K^{n-1} \right]$	$i_K^{n+1} = \frac{1}{R_T} v_K^{n+1} + C_T \frac{v_K^{n+1} - v_K^n}{\Delta t}$
resistive termination 	$v_K^{n+1} = v_K^n \left( 1 - \frac{R'_K \Delta t}{L'_K} - \frac{\Delta t R_T}{L'_K \Delta x} \right) + v_{K-1}^n \frac{\Delta t R_T}{L'_K \Delta x}$	$i_K^{n+1} = \frac{1}{R_T} v_K^{n+1}$
open termination 	$v_K^{n+1} = v_{K-1}^{n+1}$	$i_K^{n+1} = 0$
resistive voltage source termination 	$v_k^{n+1} = v_k^n \left( 1 - \frac{\Delta t R'_1}{L'_1} \frac{\Delta t R_S}{L'_1 \Delta x} \right) + \frac{\Delta t R_S}{L'_1 \Delta x} v_{k+1}^n + \frac{\Delta t R'_1}{L'_1} v_S^n + \Delta t \frac{\partial v_S^n}{\partial t}$	$i_1^{n+1} = \frac{v_S^{n+1}(t) - v_1^{n+1}}{R_S}$

a specific conductor. The details of the derivation are given in Appendix A. The electrostatic potential, magnetic field, and the geometrical basis of the three-rod probe for calculat-

ing these parameters are shown in Fig. 1. The transmission line parameters per unit length for the three rod probe with

solver HFSS<sup>TM</sup> from Ansoft Inc. First, we determined the transmission line parameters for a two rod probe. The differences between the numerical values and the exact solution are less than 1%. We then numerically evaluate the transmission line parameters of a three-rod probe using HFSS and fit them to an appropriately parameterized function. The results of the analytical model and the numerical simulations are shown in Figs. 2–3. Table 2 presents the used fit functions and their corresponding parameters.

Generally, the accuracy of results obtained from finite element analysis strongly depends on mesh size (Volakis et al., 1984): the smaller the tetrahedral mesh elements are, the better is the precision of results. At the same time, memory and

computation time increase considerably. For  $\kappa > 5$  we get an excellent agreement between the analytic approximation and the heuristic fit basing on the numerical simulation. For  $\kappa \leq 5$  the analytic approximation becomes inaccurate and the numeric simulation starts to oscillate. This is a problem of the discretization and can be alleviated by using a machine with more memory.

Calculating the propagation velocity with the fit functions for  $L'$  and  $C'$ , via  $c = \frac{1}{\sqrt{L'C'}}$ , the maximum relative deviation of the speed of light  $c_0$  is 0.14% over  $\kappa = 1.5 \dots 25$ . For the two three rod TDR probes we use  $\kappa$  is 4.69 and 6.25 so we get an error in speed of light  $c_0$  of 0.12% and 0.13%. The quality of the analytical model improves with increasing  $\kappa$ , corresponding more and more to the situation of infinitely thin line charges and current filaments, respectively.

## 2.2 Time domain dispersive dielectric modeling

Experience gained from TDR traces measured in the field has shown that it is mandatory to consider dispersive dielectric soil properties. We start with a Debye model using one single relaxation frequency (Debye, 1929; Nyfors and Vainikainen, 1989; Taflove, 1998). The Debye model describes the orientation polarization of polar molecules. Let us think of an electric field, switched on instantaneously. The polar molecules turn and the polarization evolves exponentially, with a time constant  $\tau$ , to its final state. The relative dielectric permittivity  $\epsilon_r$  as a function of frequency is then:

$$\epsilon_r(\omega) = \epsilon'_\infty + \frac{\epsilon'_s - \epsilon'_\infty}{1 + j\omega\tau}. \quad (19)$$

Here  $\epsilon'_\infty$  is the permittivity at infinite frequency, where the orientation polarization of the molecules has no time to develop. The static permittivity  $\epsilon'_s$  corresponds to a state where the orientation polarization has had sufficient time to develop fully. For solving the transmission line equations in the time domain, we transform Eq. (19) into the time domain.

$$\epsilon_r(t) = \epsilon'_\infty \delta(t) + \frac{\Delta\epsilon'}{\tau} e^{-\frac{t}{\tau}} U(t) \quad (20)$$

with  $\Delta\epsilon'_r = \epsilon'_s - \epsilon'_\infty$ . We end up with a time-dependent capacitance per unit length  $C'(t)$ , which is split into a time-dependent and a time-independent part:

$$C'(t) = C'_0 \epsilon_r(t) \quad (21)$$

Equation (21) with Eqs. (2) and (1) are discretized, using central finite differences both in space and in time. We obtain the update procedure for the voltage and current:

$$v_k^{n+1} = -\frac{2\Delta t G'_k}{C'_{0k} \epsilon'_{\infty k}} v_k^n - \frac{2\Delta t \Delta\epsilon'_k}{\epsilon'_{\infty k} \tau_k} v_k^n + v_k^{n-1} - \frac{\Delta t}{C'_{0k} \epsilon'_{\infty k} \Delta x} (i_{k+1}^n - i_{k-1}^n) + \frac{2\Delta\epsilon'_k \Delta t}{\tau_k^2 \epsilon'_{\infty k}} \psi_k^n \quad (22)$$

$$i_k^{n+1} = -\frac{2R'_k \Delta t}{L'_k} i_k^n + i_k^{n-1} - \frac{\Delta t}{\Delta x L'_k} (v_{k+1}^n - v_{k-1}^n) \quad (23)$$

with the abbreviation

$$\psi_k^n = e^{-\frac{\Delta t}{\tau_k}} \psi_k^{n-1} + \frac{\Delta t}{2} \left( v_k^n + e^{-\frac{\Delta t}{\tau_k}} v_k^{n-1} \right). \quad (24)$$

The detailed calculation for this discretization can be found in Appendix B.

## 2.3 Hierarchical optimization

Our profile reconstruction approach is based on Oswald et al. (2003). The non-linear inverse problem is solved iteratively with a transmission line solver to calculate TDR traces, based on a given profile of electric parameters. The forward solver is embedded into a global optimizer based on a genetic algorithm (Levine, 1996; Rahmat-Samii and Michielssen, 1999) which delivers electric parameter profiles, adapted according to their fitness. Fitness is a quantity which is roughly inversely proportional to the trace mismatch:

$$m = \sum_{n=N_{\text{start}}}^{N_{\text{stop}}} |v_{\text{meas}}(n\Delta t) - v_{\text{calc}}(n\Delta t)|, \quad (25)$$

We use the sum of absolute values of the difference between calculated and measured TDR traces in contrast to the sum of squared differences (Oswald et al., 2003) because it is a robust estimator, typically used for non-Gaussian errors. In contrast the sum of squared differences, the  $L^2$ -norm, is only applicable to Gaussian noise. The genetic algorithm operates on bit-strings which are mapped to real numbers to produce the electric parameter profiles. Hence the electric parameters are inherently discretized. Using a sufficient number of bits per parameter we provide a fine-grained set of values. The efficiency of profile reconstruction depends on the genetic algorithm's parameters: mutation rate, crossover probability and population size. The corresponding values are listed in Tables 4 and 6.

While Oswald et al. (2003) achieve to solve the problem, there are still issues, namely (i) it is computationally intensive due to a large number of forward problem runs and (ii) the resulting electric parameter profiles may exhibit oscillatory behavior even if their average corresponds to the converged state.

To reduce the computational burden and to achieve smoother parameter profiles we have implemented a hierarchical optimization scheme (Fig. 4). The scheme starts out with a coarse spatial resolution which is increased as convergence rate decreases. For assessing the degree of convergence we calculate the envelope of the fitness and approximate its slope with a line (Fig. 5). An envelope point (squares at green line) is retrieved as the maximum fitness value of  $N$  consecutive individuals, in our case  $N=30$ . A complete envelope consists of  $M$  such points. As soon as the next  $N$  individuals have been calculated, the oldest envelope point is

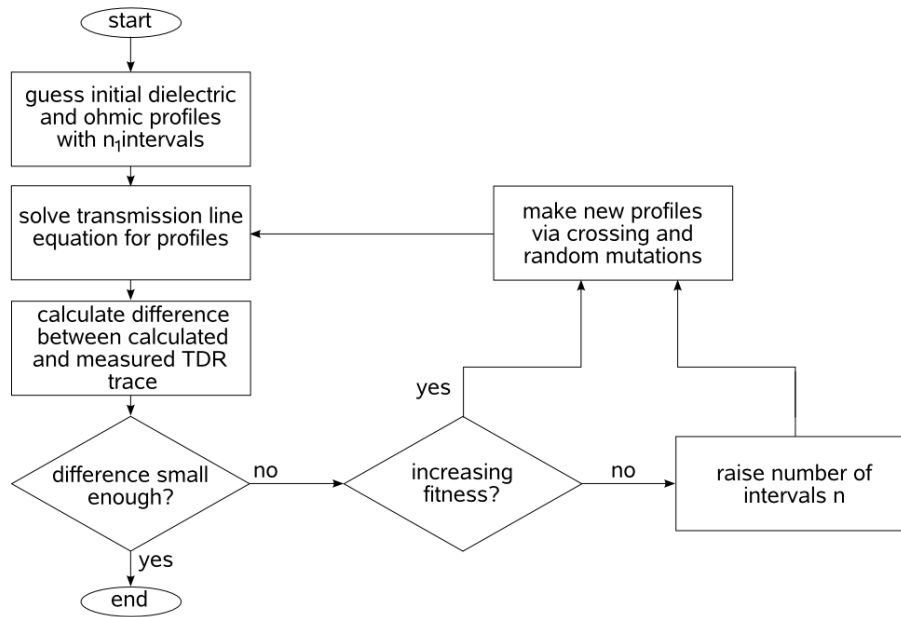

Fig. 4. Flowchart for the hierarchical optimization.

Table 3. Parameters used for calculation of synthetic TDR traces for validation and demonstration of termination conditions and the dispersive media, for all: probe length=0.1 m, TDR rise time  $t_{rise}=300$  ps,  $\kappa=10$ , conductor diameter  $D=4$  mm.

Figure number	$\epsilon'_{\infty}$	$\Delta\epsilon'$	$f_{rel}$ (MHz)	$\sigma' \left( \frac{S}{m} \right)$	$R_T$ ( $\Omega$ )	$C_T$ (F)	$t_{sec}$	$\Delta x$ (m)
6	10	–	–	$1 \cdot 10^{-30}$	–	–	0.25	$1.2 \cdot 10^{-3}$
7	1	–	–	$1 \cdot 10^{-30}$	1438.8	$5.0 \cdot 10^{-12}$	0.10	$5.0 \cdot 10^{-4}$
9	10	10	100	$1 \cdot 10^{-30}$	–	–	0.25	$1.2 \cdot 10^{-3}$
8 (green line)	10	–	–	$1 \cdot 10^{-30}$	113	–	0.20	$1.0 \cdot 10^{-3}$
8 (red dotted line)	10	–	–	$1 \cdot 10^{-30}$	1436.8	$5 \cdot 10^{-12}$	0.20	$1.0 \cdot 10^{-3}$
8 (blue dashed line)	10	–	–	$4 \cdot 10^{-2}$	–	–	0.20	$1.0 \cdot 10^{-3}$
10 (green line)	10	10	10	$1 \cdot 10^{-30}$	–	–	0.20	$1.0 \cdot 10^{-3}$
10 (red dotted line)	10	5	100	$1 \cdot 10^{-30}$	–	–	0.20	$1.0 \cdot 10^{-3}$
10 (blue dashed line)	10	10	100	$1 \cdot 10^{-30}$	–	–	0.20	$1.0 \cdot 10^{-3}$

discarded and the whole envelope section is moved one point ahead with respect to the sequence of evaluated individuals. If the majority of envelope points is below the line (red line), with the slope defined in the job file, the spatial resolution is increased by cutting the intervals of dielectric properties into halves. The new intervals are initialized with the same dielectric properties, as the old intervals had at the same location. The optimization stops if a previously specified spatial resolution is reached and the fitness does not increase.

### 3 Results

#### 3.1 Validation of parallel RC boundary condition

We show the results of TDR traces calculated for different probe termination conditions with a non-dispersive dielectric permittivity between the probe conductors, for all parameters cf. Table 3. Figure 6 shows a comparison for the open termination, calculated with HFSS<sup>TM</sup> and our own code. All traces generated with HFSS<sup>TM</sup> were calculated under the assumptions (i) that the TDR signal source is connected directly to the probe and (ii) that the source has the same impedance as the probe. Therefore, there is no initial reflection.

The traces calculated with HFSS<sup>TM</sup> and our code are not totally identical. The small differences can not be neglected

**Fig. 5.** Determination of the criteria when to increment spatial resolution.

**Fig. 7.** Calculated TDR trace with HFSS (blue dashed line) and our code (green line) for two-rod probe with length  $l=0.1$  m,  $D=4$  mm,  $\kappa=10$ ,  $\epsilon'_{\infty}=1$ ,  $\sigma=10^{-30}$  S/m, not dispersive, parallel resistive capacitive termination,  $R_T=1436.8 \Omega$ ,  $C_T=5.0 \cdot 10^{-12}$  F.

**Fig. 6.** Calculated TDR trace with HFSS (blue dashed line) and our code (green line) for two-rod probe with length  $l=0.1$  m,  $D=4$  mm,  $\kappa=10$ ,  $\epsilon'_{\infty}=10$ ,  $\sigma=10^{-30}$  S/m, not dispersive, infinite termination.

**Fig. 8.** Calculated TDR trace with our code for two-rod probe with length  $l=0.1$  m,  $D=4$  mm,  $\kappa=10$ ,  $\epsilon'_{\infty}=10$ , not dispersive: (i) (green line)  $\sigma=10^{-30}$  S/m, resistive termination,  $R_T=113.0 \Omega$ ; (ii) (blue dashed line)  $\sigma=10^{-30}$  S/m, parallel resistive capacitive termination,  $R_T=1436.8 \Omega$ ,  $C_T=5 \cdot 10^{-12}$  F; (iii) (red dashed line)  $\sigma=4 \cdot 10^{-2}$  S/m, infinite termination. The discontinuity of impedance form TDR source to the probe causes the reflection at 0.3 ns.

and are not a pure result of numeric simulation. We calculate the TDR probe fully 3-dimensional with HFSS<sup>TM</sup> so it includes the finite length of the transmission line. Our code uses the ideal transmission line equations, only valid for infinite long transmission lines. The influence of this effect is important in the content of spatial reconstruction of dielectric profiles. We expect a higher systematic error for the reconstructed dielectric parameters at the end of the probe, than for the rest.

Figure 7 shows the result of a probe with parallel resistive capacitive termination. At the reflection we can see the effect of the resistive capacitive termination: (i) in the beginning it behaves like a short circuit; (ii) if the capacitor is completely charged, it behaves like a pure resistive termination; (iii) and the edges of the reflections are smoothed. In Fig. 8 different termination conditions are calculated with our code. The TDR source here has an impedance of  $50 \Omega$ , therefore the first reflection results from the source-probe-transition, the second from the end of the probe. After these, there are multiple reflections. The TDR probe terminated with the probe's impedance produces the green trace. There are no reflections resulting from the end of the probe, as expected. The red

dotted TDR trace demonstrates the effect of ohmic conductivity between the probe conductors with an open terminated probe.

### 3.2 Validation of dispersive dielectric TDR model

Figures 9 and 10 show the results for TDR traces calculated with dispersive media and open probe termination. At Fig. 9 we compare our code with HFSS<sup>TM</sup>. There is also a difference between the result of HFSS<sup>TM</sup> and our code. With HFSS<sup>TM</sup> we calculate the TDR probe fully 3-dimensional so that the effects of the finite length of the probe are included. Our code, as described above, does not include this effect. Figure 10 shows traces calculated with our code, assuming the TDR source has an impedance of  $50 \Omega$ . There is an initial reflection at 0.3 ns. Effects of different dispersive media can be seen: (i) The amplitude of the reflected signal decreases slowly after the initial reflection. We note that the

ohmic conductivity between the probe rods can be neglected; (ii) the reflections tend to smooth with the increasing effect of dispersion.

### 3.3 Hierarchical reconstruction of water content profiles

#### 3.3.1 Traces measured in non-dispersive media

In Figs. 12–14 we show hierarchical reconstructions of the dielectric parameters for the same traces used by Oswald et al. (2003). The probe was in a sand tank with water content  $\theta_1=\theta_3=0$  and  $\theta_2$  was varied. The experimental setup is sketched in Fig. 11. Relevant optimization parameters are given in Table 4. The vertical dashed lines in fitness and error

history indicate an increase in spatial resolution. The number of spatial intervals are given in red in history and fitness.

For Fig. 12 with water content  $\theta_2=0$  we see no significant increase in fitness, when increasing the spatial resolution during the optimization. For traces with inhomogeneous water content, Fig. 13:  $\theta_2=0.05$ , Fig. 14:  $\theta_2=0.10$ , we see an increase in fitness, if the spatial resolution is commensurate with the region where the water content varies. The hierarchical reconstruction requires about an order of magnitude less iterations for the same traces as the reconstruction with full spatial resolution right from the optimization's start. Additionally, the hierarchical approach leads to considerably smoother profiles when compared to Oswald et al. (2003).

**Fig. 11.** Experimental setup by Oswald et al. (2003): segmented sand tank with different water contents.

**Table 5.** Comparison of volumetric measured water content, permittivity of composite with Roth et al. (1990)’s model ( $\alpha=0.5$ ,  $\epsilon_{soil}=5$ ,  $\eta=0.322$ ) and the reconstructed relative dielectric permittivity corresponding to Fig. 15.

cally in a sand tank. The probe ends in fully water saturated sand, while the sand at the probe head is dry. So we expect a strong gradient in the water content along the probe. We measure the water content volumetrically in different depths (probe head corresponds to  $z=0.0$  m). If we compare the reconstructed dielectric parameters with volumetrically measured parameters at Table 5, we see that they are in the same order; resistivity and permittivity increase in the longitudinal direction (for this comparison we use the relative dielectric permittivity  $\epsilon'_s = \epsilon'_\infty + \Delta\epsilon'$ ). Only the volumetric measurement at depth 10...14 cm and the reconstructed value at 10.0...12.5cm do not correspond. We denote that the different depths are not quite compatible: there is an uncertainty in the depth of the volumetric measurement and the TDR probe, is not calibrated.

In the discretized voltage update procedure, Eq. (22) the parameters describing the dispersion appear only as products. If one of the reconstructed dispersion parameters  $f_{rel}$  or  $\Delta\epsilon'$  approaches zero, the other dispersion parameter has no effect and the result for it is not relevant. For example in Fig. 15 we get for  $x=0...2.5$  cm a relaxation frequency of round about 200 MHz. That does not mean, that the sand there has this relaxation frequency, because the  $\Delta\epsilon'$  is nearly zero. In addition, the relaxation frequency  $f_{rel}$  of water saturated sand is in the range of some GHz (Robinson et al., 2003). So the Debye model for dispersion has no strong gradient in dielectric permittivity in the most relevant frequency

**Fig. 12.** Reconstruction of synthetic profile,  $\theta_2=0$ . Individual 7547 with error:  $2.9 \cdot 10^7$  and fitness: 3.4. Effective relative permittivity  $\epsilon_c$  corresponding to  $\theta_2$ : (i) travel time evaluation  $\epsilon_c=2.78$ ; (ii) Roth et al. (1990)'s model  $\epsilon_c=2.49$ .

range of our TDR. It is not easy to extrapolate the relaxation frequency very well and we get large errors for it with the frequency range of our TDR. Nevertheless the dispersion can not be neglected. Inclusion of dielectric dispersion is required to invert this TDR trace; reconstruction without dispersion will inevitably fail.

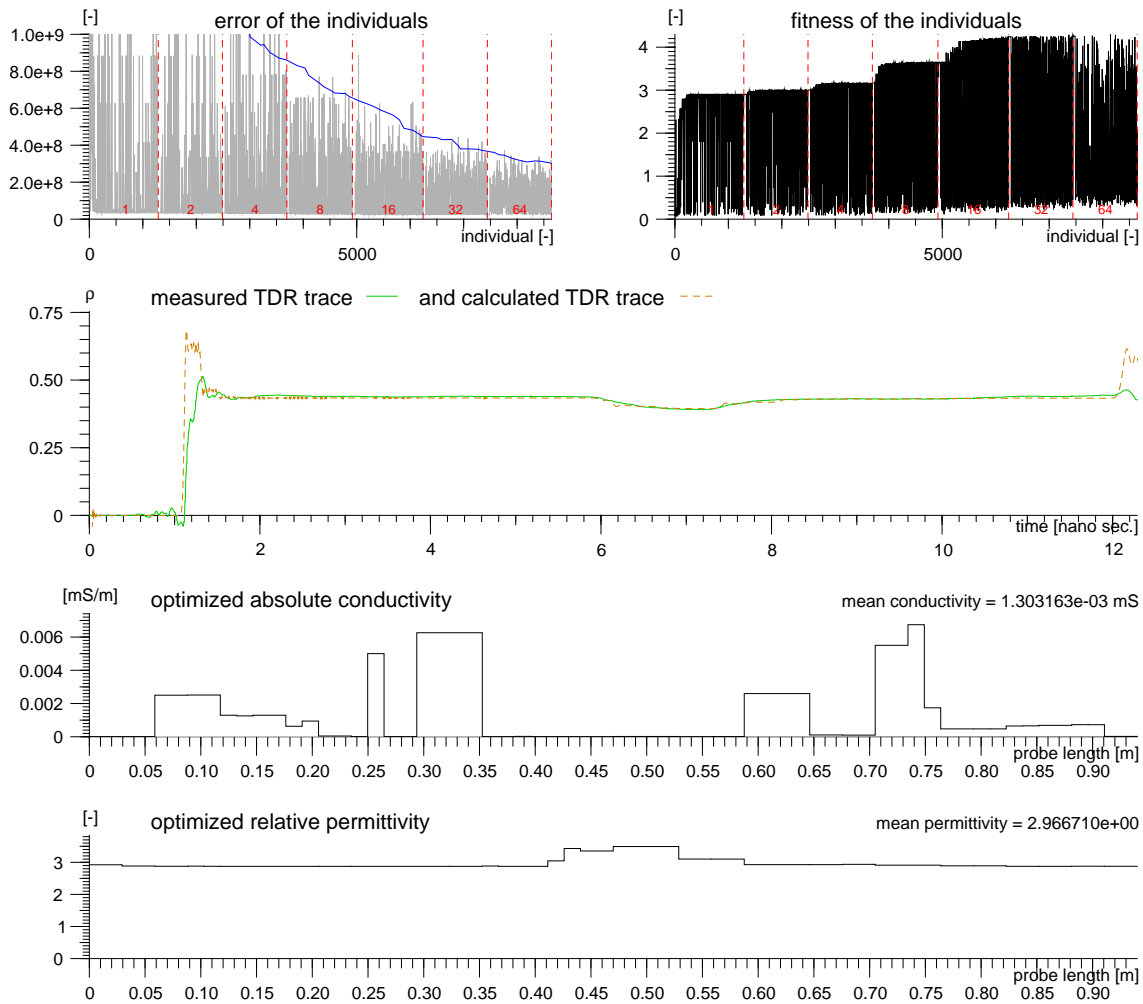

### 3.3.3 Traces measured under field conditions

In Figs. 16–19 we show hierarchical reconstructions of TDR traces measured under field condition at the Grenzhof (Heidelberg, Germany) test site (Wollschläger and Roth, 2005). The traces were recorded with a “Campbell TDR 100” using a Campbell probe “CS610”. Essential TDR properties and the parameters used in the optimization to produce Figs. 16–19 are shown in Table 6. The steps in all these measured traces result from finite time resolution in recording. The first reflection in all traces is a result of the TDR probe head. The head is simulated with a transmission line section. Gen-

erally, we can fit the transmission line parameters for this part with our simulation. Because the parameters are constant for every single probe, we fit them manually and fix the respective parameters in the job file, because it would unnecessarily slow down the optimization if it was fitted for every trace from scratch once again. We particularly note Fig. 16. More conventional techniques (e.g. Roth et al., 1990) experience severe problems, may even fail, to evaluate this trace, because there is no sharp reflection from the end of probe.

## 4 Discussion

We have derived analytical expressions for the transmission line parameters of a three rod probe, based on an approximate model and validated it with numerical simulations; such expressions, to our knowledge, have not been presented in the area of the TDR literature yet. The analytical model has been benchmarked against results obtained from an established

**Fig. 13.** Reconstruction of synthetic profile,  $\theta_2=0.05$ . Individual 8146 with error:  $2.3 \cdot 10^7$  and fitness: 4.3. Effective relative permittivity  $\epsilon_c$  corresponding to  $\theta_2$ : (i) travel time evaluation  $\epsilon_c=3.57$ ; (ii) Roth et al. (1990)'s model  $\epsilon_c=3.90$ .

commercial solver. We mention that the analytical model is most accurate for larger  $\kappa$  and becomes less accurate at very low  $\kappa$ . This is caused by the fact that in the situation of large, closely spaced probe rods the electric and magnetic fields, obtained from the assumption of infinitely thin and infinitely extended line charges and current filaments, respectively, increasingly differ from the true fields. Nevertheless, it is remarkable how accurate its predictions are at larger  $\kappa$ .

We have validated our dispersive TDR code by comparing synthetically calculated traces from our code and HFSS<sup>TM</sup>, for both dispersive and non-dispersive dielectric properties. We mention that dispersive dielectrics impose more stringent restrictions onto the time-step of the explicit integration scheme to keep it stable. This is related to the relative position of the dielectric relaxation frequency and the dominant frequency content of the TDR signal source.

We have used a hierarchical approach to reconstruct electric parameter profiles from TDR traces measured in the lab-

oratory with minimal electrical losses. The hierarchical approach reduced the number of forward solutions required and leads to considerably smoother profiles. We consider hierarchical optimization to be a definite advance and speculate that this will hopefully support the deployment of TDR profile reconstruction to field applications. The reconstructed profiles shown in the paper are computed on a personal computer (2 GHz clock) within a few hours. The actual computation time depends strongly on the measurement configuration, e.g. probe length, TDR rise time, dispersive character, upper and lower limits for the reconstructed parameters. The rather massive computational effort results from the requirement to employ a globally optimizing algorithm since this type of problem is often vulnerable to local minima. We chose a genetic algorithm which is known to be very robust. Algorithmic improvements are easily accomplished, for instance by using hybrid approaches, but they were not deemed essential for this prove-of-concept study.

**Fig. 14.** Reconstruction of synthetic profile,  $\theta_2=0.10$ . Individual 7977 with error:  $2.7 \cdot 10^7$  and fitness: 3.8. Effective relative permittivity  $\epsilon_c$  corresponding to  $\theta_2$ : (i) travel time evaluation  $\epsilon_c=5.09$ ; (ii) Roth et al. (1990)’s model  $\epsilon_c=5.64$ .

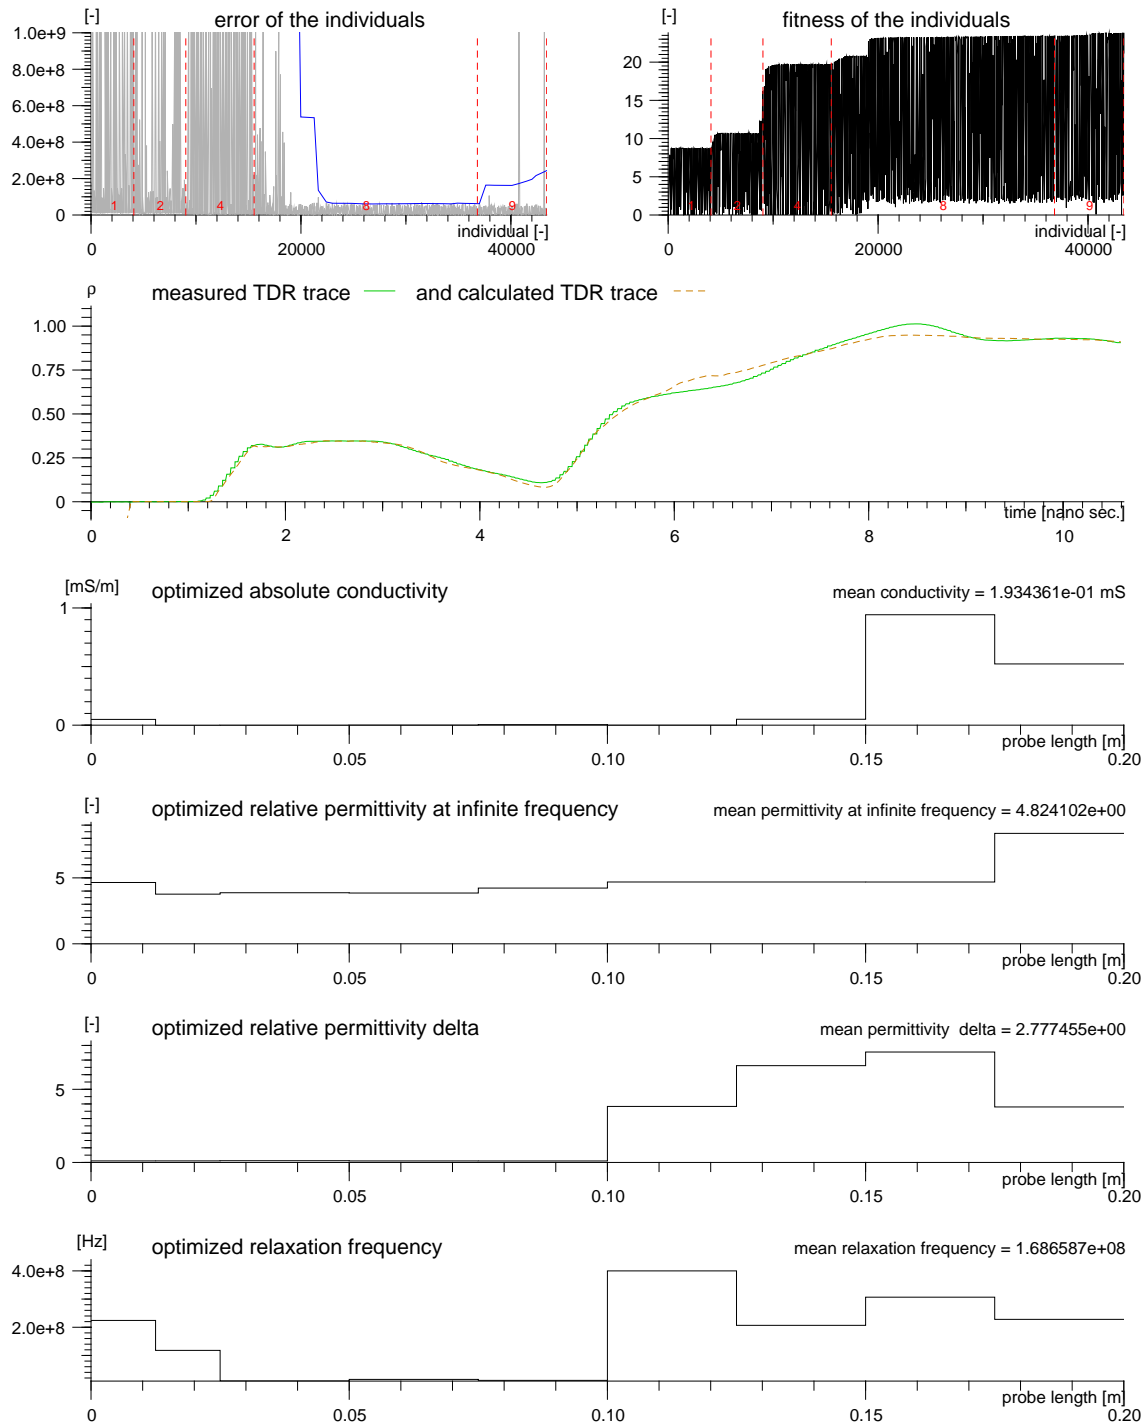

Numerical experimentation for reconstructing TDR traces measured in the field has definitely shown that dispersive dielectric properties must be included in the numerical model. Only when using dispersive dielectrics can such TDR traces be recovered numerically; using frequency-independent permittivity alone can not account for the the shape of the traces.

If the frequency range of the TDR instrument is well below the relaxation frequency, dispersion becomes less important. On the other hand, if the TDR’s frequency content and the relaxation frequency have a significant overlap, then dispersion will be quite pronounced. The “Campbell TDR 100” has  $f_{3\text{ dB}} \approx 740$  MHz. The relaxation frequencies extracted by the optimization are within this range and therefore dispersion is relevant (Robinson et al., 2003, 2005).

We note that in all cases we used a relatively small mutation probability, 0.01, and a significantly higher cross-over probability, 0.6. Increasing the mutation probability results in a more diverse population but does not seem to accelerate the convergence behavior. On the other hand, using a

relatively high cross-over probability ensures efficient reconstruction. The error and fitness histories represent the search in a wide parameter range. For some individuals we obtain a high error and a low fitness, respectively. The low fitness of some individuals give the black filled area in fitness history. Note that the error and fitness history are line plots. The high errors are cut off in the plots so that the relevant sector is visible. Additionally, the error’s running average is plotted in the diagrams with a blue line.

Furthermore, a more realistic numerical boundary condition using a parallel resistive-capacitive impedance is essential. Using all these model components we succeed in reconstructing field measured TDR traces over a wide spectrum of dielectric field permittivity and conductivity. We note that dielectric loss caused by the dispersive Debye model is fundamentally different from ohmic loss. We finally mention that our profile reconstruction does not require any a priori information whatsoever in order to succeed.

## 5 Conclusions

A robust, accurate and efficient method has been presented for reconstructing dielectric and ohmic conductivity profiles along TDR traces, for both laboratory and field traces. Different boundary conditions have been implemented for modeling a wide variety of probe terminations encountered in experimental setups. Dispersive dielectric properties are reconstructed and may be of interest for extracting even more information from TDR traces, such as a distinction between bound and free water, so characteristic for clay and loam soils (Ishida et al., 2000).

Now, that TDR technology using conventional, transverse-electric-magnetic (TEM) probes has reached considerable maturity we speculate that it could be worthwhile to address more advanced concepts, such as the single-rod probe using a transverse-magnetic mode of propagation, (Oswald et al., 2004; Nussberger et al., 2005). Such probe types may pose modeling challenges but they also hold the promise of avoiding problems of probes with multiple conducting rods.

The code developed in this work will be publicly available at <http://www.iup.uni-heidelberg.de/institut/forschung/groups/ts/tools> in due course.

## Appendix A

### Three-rod probe transmission line parameters

The electric potential of a line charge, with diameter  $D$ , in  $x$ -direction, cf. Fig. 1, outside the conductor is given by

$$\Phi_{el}(y, z) = \Phi_0 - \frac{Q}{\ell} \frac{1}{2\pi\epsilon} \ln\left(\sqrt{y^2 + z^2}\right) \quad (\text{A1})$$

with potential  $\Phi_0$  at infinity and line charge density  $\frac{Q}{\ell}$ . By convention, the potential at infinity is set to zero. We consider three parallel, infinitely long line charges, Fig. 1. The total potential, outside the conductors, is the superposition of of the single rod potential, Eq. (A1):

$$\Phi_{el} = \frac{Q}{\ell} \frac{1}{2\pi\epsilon} \left\{ \frac{1}{2} \ln\left[\left(y^2 + (z-d)^2\right)\left(y^2 + (z+d)^2\right)\right] - \ln\left[y^2 + z^2\right] \right\}. \quad (\text{A2})$$

The capacitance per unit length between conductor 0 and 1 is

$$C'_{01} = \frac{Q}{V} \quad (\text{A3})$$

with the potential difference  $V$  between the two nearest points of conductor 0 and 1:  $(y=0, z=\frac{D}{2})$  and  $(y=0, z=d-\frac{D}{2})$ .

$$V = \Phi_{el}\left(y=0, z=\frac{D}{2}\right) - \Phi_{el}\left(y=0, z=d-\frac{D}{2}\right)$$

$$= \frac{Q}{\ell} \frac{1}{2\pi\epsilon} \left[ \ln\left(\frac{4d^2 - D^2}{4dD - D^2}\right) + \ln\left(\frac{2d-D}{D}\right) \right]. \quad (\text{A4})$$

Due to the symmetry of the conductor arrangement the capacitance of a three-rod probe is twice the capacitance, resulting from Eq. (A4). Therefore, the capacitance per unit length is

$$C' = \frac{4\pi\epsilon}{\ln\left(\frac{4d^2 - D^2}{4dD - D^2}\right) + 2\ln\left(\frac{2d-D}{D}\right)}. \quad (\text{A5})$$

The conductance per unit length  $G'$  of the medium between the rods is calculated from the electric potential. We use Ohm's law

$$\mathbf{j} = \sigma \mathbf{E} \quad (\text{A6})$$

with current density  $\mathbf{j}$ , ohmic conductivity  $\sigma$  and the electric field  $\mathbf{E} = -\nabla\Phi_{el}$ . The current between conductor 0 and 2 per length  $\ell$  is the integral of  $\mathbf{j} \cdot \mathbf{F}_1$  with  $\mathbf{F}_1 \perp z$ -axis:

$$\begin{aligned} I &= \int_0^\ell \int_{-\infty}^{+\infty} j_z dy dx \\ &= \sigma \ell \int_{-\infty}^{+\infty} E_z dy. \end{aligned} \quad (\text{A7})$$

Using the electric potential, Eq. (A2), and evaluating the integral at  $z = -\frac{d}{2}$  we obtain

$$I = \frac{\sigma}{\epsilon} Q. \quad (\text{A8})$$

With the potential difference, Eq. (A4), we compute the conductivity per unit length between conductor 0 and 2:

$$G'_{02} = \frac{I'}{V}. \quad (\text{A9})$$

Again, due to the symmetry of the conductor arrangement, Fig. 1, the conductivity per unit length of the three-rod TDR probe is twice  $G'_{02}$ :

$$G' = \frac{4\pi\sigma}{\ln\left(\frac{4d^2 - D^2}{4dD - D^2}\right) + 2\ln\left(\frac{2d-D}{D}\right)}. \quad (\text{A10})$$

The absolute value of the magnetic field outside a wire infinitely, extended in  $x$ -direction with radius  $\frac{D}{2}$ , conducting current  $I$ , using the definition  $r = \sqrt{y^2 + z^2}$  is

$$r \geq \frac{D}{2} : \quad |\mathbf{B}(r)| = \frac{\mu_0 I}{2\pi r}. \quad (\text{A11})$$

The magnetic induction outside a wire for the three-rod probe is given as a superposition of Eq. (A11)

$$\begin{aligned} |\mathbf{B}(y, z)| &= \frac{\mu_0 I}{2\pi} \left( \frac{2}{\sqrt{y^2 + z^2}} + \frac{1}{\sqrt{y^2 + (d-z)^2}} \right. \\ &\quad \left. - \frac{1}{\sqrt{y^2 + (d+z)^2}} \right) \end{aligned} \quad (\text{A12})$$

where we have implicitly assumed that we only need the field in a plane parallel to the line connecting the centers of the three conductors, hereby ensuring that the directions of the three magnetic induction components are all parallel. For the inductance only the magnetic flux  $\Phi_m$  outside the wires is relevant. With Eq. (A12) the magnetic flux through the area  $F_2 \perp y$ -axes with  $F_2 = (d-D) \cdot \ell$  at  $y=0$  is

$$\begin{aligned} \Phi_m &= \ell \int_{\frac{D}{2}}^{d-\frac{D}{2}} B_y(z) dz \\ &= \frac{\mu_0 I \ell}{2\pi} \left[ 3 \ln \left( \frac{2d-D}{D} \right) + \ln \left( \frac{2d+D}{4d-D} \right) \right]. \end{aligned} \quad (\text{A13})$$

The self inductance per unit length between conductor 0 and 1 is

$$L' = \frac{\Phi_m}{I}. \quad (\text{A14})$$

Due to the symmetry of the arrangement the inductance of the three rod probe is one half the inductance that follows from the magnetic flux Eq. (A14). So the inductance per unit length is

$$L' = \frac{3\mu_0}{4\pi} \left[ \ln \left( \frac{2d-D}{D} \right) + \frac{1}{3} \ln \left( \frac{2d+D}{4d-D} \right) \right]. \quad (\text{A15})$$

## Appendix B

### Discretization of dispersive dielectric medium

To obtain the update procedure for the voltage we insert Eq. (21) into Eq. (2):

$$\begin{aligned} \frac{\partial i}{\partial x} &= - \left( G' + C'(t) \otimes \frac{\partial}{\partial t} \right) v \\ &= -G'v - C'_0 \left[ \left( \epsilon'_\infty \delta(t) + \frac{\Delta \epsilon'}{\tau} e^{-\frac{t}{\tau}} U(t) \right) \otimes \frac{\partial v}{\partial t} \right] \\ &= -G'v - C'_0 \epsilon'_\infty \int_{-\infty}^{+\infty} \frac{\partial v(t')}{\partial t'} \delta(t-t') dt' \\ &\quad - C'_0 \frac{\Delta \epsilon'}{\tau} \int_{-\infty}^{+\infty} e^{-\frac{t-t'}{\tau}} U(t-t') \frac{\partial v(t')}{\partial t'} dt'. \end{aligned} \quad (\text{B1})$$

The second term of Eq. (B1) is

$$C'_0 \epsilon'_\infty \int_{-\infty}^{+\infty} \frac{\partial v(t')}{\partial t'} \delta(t-t') dt' = C'_0 \epsilon'_\infty \frac{\partial v(t)}{\partial t}. \quad (\text{B2})$$

The integral of the third term leads, using partial integration, to

$$\int_{-\infty}^{+\infty} e^{-\frac{t-t'}{\tau}} U(t-t') \frac{\partial v(t')}{\partial t'} dt' = \int_{-\infty}^t e^{-\frac{t-t'}{\tau}} \frac{\partial v(t')}{\partial t'} dt'$$

$$\begin{aligned} &= \left[ e^{-\frac{t-t'}{\tau}} v(t') \right]_{t'=-\infty}^{t'=t} - \int_{-\infty}^t \frac{1}{\tau} e^{-\frac{t-t'}{\tau}} v(t') dt' \\ &= v(t) - \frac{1}{\tau} \int_{-\infty}^t e^{-\frac{t-t'}{\tau}} v(t') dt'. \end{aligned} \quad (\text{B3})$$

We agree on the following abbreviation:

$$\psi(t) := \int_{-\infty}^t e^{-\frac{t-t'}{\tau}} v(t') dt'. \quad (\text{B4})$$

We finally obtain the transmission line Eq. (2) for a Debye medium

$$\begin{aligned} \frac{\partial i(t)}{\partial x} &= -G'v(t) - C'_0 \epsilon'_\infty \frac{\partial v(t)}{\partial t} - C'_0 \frac{\Delta \epsilon'}{\tau} v(t) \\ &\quad + C'_0 \frac{\Delta \epsilon'}{\tau^2} \psi(t). \end{aligned} \quad (\text{B5})$$

The discretized version of  $\psi$  is

$$\psi_k^n = \psi(t)|_{x_k, t_n} \quad (\text{B6})$$

$$= \int_{-\infty}^{n\Delta t} e^{-\frac{n\Delta t-t'}{\tau_k}} v_k(t') dt' \quad (\text{B7})$$

$$= \int_{-\infty}^{n\Delta t} e^{-\frac{n\Delta t}{\tau_k}} e^{\frac{t'}{\tau_k}} v_k(t') dt' \quad (\text{B8})$$

$$\begin{aligned} &= e^{-\frac{n\Delta t}{\tau_k}} \left( \int_{-\infty}^{(n-1)\Delta t} e^{\frac{t'}{\tau_k}} v_k(t') dt' \right. \\ &\quad \left. + \int_{(n-1)\Delta t}^{n\Delta t} e^{\frac{t'}{\tau_k}} v_k(t') dt' \right) \end{aligned} \quad (\text{B9})$$

$$\begin{aligned} &= e^{-\frac{\Delta t}{\tau_k}} e^{-\frac{(n-1)\Delta t}{\tau_k}} \left( \int_{-\infty}^{(n-1)\Delta t} e^{\frac{t'}{\tau_k}} v_k(t') dt' \right. \\ &\quad \left. + \int_{(n-1)\Delta t}^{n\Delta t} e^{\frac{t'}{\tau_k}} v_k(t') dt' \right). \end{aligned} \quad (\text{B10})$$

With these expansions we write the first integral as a function of  $\psi_k^{n-1}$  and the second integral is evaluated using the trapezoidal rule.

$$\begin{aligned} \psi_k^n &= e^{-\frac{\Delta t}{\tau_k}} \psi_k^{n-1} + \frac{1}{2} e^{-\frac{\Delta t}{\tau_k}} e^{-\frac{(n-1)\Delta t}{\tau_k}} \Delta t \\ &\quad \cdot \left( e^{\frac{n\Delta t}{\tau_k}} v_k^n + e^{\frac{(n-1)\Delta t}{\tau_k}} v_k^{n-1} \right) \end{aligned} \quad (\text{B11})$$

$$= e^{-\frac{\Delta t}{\tau_k}} \psi_k^{n-1} + \frac{\Delta t}{2} \left( v_k^n + e^{-\frac{\Delta t}{\tau_k}} v_k^{n-1} \right) \quad (\text{B12})$$

With this rearrangement we can calculate  $\psi_k^n$  from  $\psi_k^{n-1}$ . There is no need to save the total history of  $v(t)$  which results in considerable memory savings. The derivatives in Eqs. (B5) and (1) are discretized, accurate to 2nd order (Taflove, 1998) using central finite differences both in space and in time. We obtain

$$\frac{i_{k+1}^n - i_{k-1}^n}{2\Delta x} = -G'_k v_k^n - C'_{0k} \epsilon'_{\infty k} \frac{v_k^{n+1} - v_k^{n-1}}{2\Delta t} - C'_{0k} \frac{\Delta \epsilon'_k}{\tau_k} v_k^n + C'_{0k} \frac{\Delta \epsilon'_k}{\tau_k^2} \psi_k^n \quad (\text{B13})$$

$$\frac{v_{n+1}^n - v_{k-1}^n}{2\Delta x} = -R'_k i_k^n - L'_k \frac{i_k^{n+1} - i_k^{n-1}}{2\Delta t}. \quad (\text{B14})$$

By rearranging terms this leads to the update procedure for voltage and current

$$v_k^{n+1} = -\frac{2\Delta t G'_k}{C'_{0k} \epsilon'_{\infty k}} v_k^n - \frac{2\Delta t \Delta \epsilon'_k}{\epsilon'_{\infty k} \tau_k} v_k^n + v_k^{n-1} - \frac{\Delta t}{C'_{0k} \epsilon'_{\infty k} \Delta x} (i_{k+1}^n - i_{k-1}^n) + \frac{2\Delta \epsilon'_k \Delta t}{\tau_k^2 \epsilon'_{\infty k}} \psi_k^n \quad (\text{B15})$$

$$i_k^{n+1} = -\frac{2R'_k \Delta t}{L'_k} i_k^n + i_k^{n-1} - \frac{\Delta t}{\Delta x L'_k} (v_{k+1}^n - v_{k-1}^n). \quad (\text{B16})$$

## Appendix C

### List of symbols

<b>B</b>	magnetic field, $\frac{\text{Vs}}{\text{m}^2} = \text{T}$ .
$c_0$	speed of light in vacuum, $\frac{\text{m}}{\text{s}}$ .
<b>C</b>	capacitance, F.
$C_T$	value of the capacitor terminating the TDR probe, F.
$C'$	capacitance per unit length of a transmission line, $\frac{\text{F}}{\text{m}}$ .
$\delta(t)$	Dirac delta function.
$\Delta x$	spatial resolution in the discretization of the transmission line equations, m.
$\Delta \epsilon' = (\epsilon'_s - \epsilon'_\infty)$	difference between static permittivity and permittivity at infinite frequency, dimensionless.

$\Delta t$	discretization width in the time domain, s.
<b>D</b>	diameter of the conductors of a two- or three-wire transmission line, m.
<b>d</b>	distance between the centers of two nearest conductors of a transmission line, m.
$\epsilon = \epsilon_0 \epsilon_r$	absolute complex dielectric permittivity, $\frac{\text{As}}{\sqrt{\text{m}}}$ .
$\epsilon(t) = \epsilon_0 \epsilon_r(t)$	absolute dielectric permittivity as function of time, $\frac{\text{As}}{\sqrt{\text{m}}}$ .
$\epsilon_0$	absolute dielectric permittivity of vacuum, $\frac{1}{\mu\text{c}^2}$ .
$\epsilon_c$	effective relative permittivity of a composite medium, dimensionless.
$\epsilon'_\infty$	real valued relative permittivity at infinite frequency in Debye model, dimensionless.
$\epsilon_r$	complex valued relative dielectric permittivity, dimensionless.
$\epsilon_{r,\text{max}}$	maximum value of relative dielectric permittivity, dimensionless.
$\epsilon_r(\omega)$	complex valued relative dielectric permittivity as a function of angular frequency of electric field, dimensionless.
$\epsilon_r(t)$	relative dielectric permittivity as a function of time, Fourier transformed of $\epsilon_r(\omega)$ , dimensionless.
$\epsilon'_s$	real valued relative permittivity at zero frequency in Debye model, dimensionless.
$\epsilon_{\text{soil}}$	relative permittivity of a soil matrix without water, dimensionless.
<b>E</b>	electric field, $\frac{\text{V}}{\text{m}}$ .
$f_{3\text{dB}}$	frequency at which amplitude of the respective function has reduced by 3 dB, Hz.
$f_{\text{max}}$	maximum frequency, Hz.
$f_{\text{rel}}$	relaxation frequency in Debye model, Hz.
<b>G</b>	conductance, S.
$G'$	conductance per unit length of a transmission line, $\frac{\text{S}}{\text{m}}$ .
<b>I</b>	current, A.
$I_T$	current at the end of the transmission line, A.
$i(x, t)$	current on a transmission line as function of position $x$ and time $t$ , A.
$i_k^n \equiv (x_k, t_n)$	current at point $k\Delta x$ at time $n\Delta t$ , A.
$i_S$	TDR source current, A.
$j$	imaginary unit, $j = \sqrt{-1}$ .
<b>j</b>	current density, $\frac{\text{A}}{\text{m}^2}$ .

$j_x, j_y, j_z$	components of current density referring to a Cartesian coordination system, $\frac{A}{m^2}$ .	$R_{skin}$	skin resistance of a conductor, $\Omega$ .
$\kappa = \frac{d}{D}$	factor of probe geometry, dimensionless.	$R_T$	value of the resistor terminating the TDR probe, $\Omega$ .
$k$	index used for the specification of spatial locations, $k \cdot \Delta x = x_k$ , dimensionless.	$\sigma(x)$	ohmic conductivity as a function of longitudinal position on the TDR probe, $\frac{S}{m}$ .
$K$	index, denoting the last index in spatial discretization, $K \cdot \Delta x = \Lambda$ , dimensionless.	$\tau = \frac{1}{2\pi f_{rel}}$	relaxation time of a dipole in the Debye model, s.
$\Lambda$	total length of TDR-probe, m.	$\theta$	volumetric water content, $\frac{m^3}{m^3}$ .
$\lambda_{min}$	minimum wavelength, m.	$\theta(x)$	volumetric water content as function of longitudinal position on the TDR probe, $\frac{m^3}{m^3}$ .
$L'$	inductance per unit length of a transmission line, $\frac{H}{m}$ .	$t$	time, s.
$l$	length of a part of TDR probe, m.	$t_{rise}$	rise time of an electrical signal, usually the time required for the signal to rise from 10 to 90% of its final value, s.
$\mu = \mu_0 \mu_r$	magnetic permeability of a material, $\frac{Vs}{Am}$ .	$t_{sec}$	time step security for explicit time domain integration, s.
$\mu_0$	magnetic permeability of vacuum, $4\pi \cdot 10^{-7} \frac{Vs}{Am}$ .	$U(t)$	Heaviside step function.
$\mu_r = (\mu'_r - j\mu''_r)$	complex valued relative magnetic permeability, equals 1 for considered soil materials, dimensionless.	$V$	voltage, V.
$\mu'_r$	real part of the complex valued relative magnetic permeability, dimensionless.	$V_T$	voltage at the end of the transmission line, V.
$\mu''_r$	imaginary part of the complex valued relative magnetic permeability, dimensionless.	$v(x, t)$	voltage on a transmission line as function of position $x$ and time $t$ , V.
$M$	number of fitness envelope points.	$v_k^n \equiv v(x_k, t_n)$	voltage at point $k\Delta x$ at time $n\Delta t$ , V.
$m$	mismatch between measured and calculated TDR trace, dimensionless.	$v_S$	TDR source voltage, V.
$N$	number of consecutive individuals, used for a fitness envelope point.	$x, y, z$	spatial coordinate, m.
$N_{start}$	index denoting start time for mismatch calculating, dimensionless.		
$N_{stop}$	index denoting stop time for mismatch calculating, dimensionless.		
$n$	index used for the specification of time, $x(n \cdot \Delta t) = x^n$ , dimensionless.		
$\omega$	angular frequency of electric field, $\frac{1}{s}$ .		
$\Phi_{el}$	electro static potential, V.		
$\psi_k^n$	$= e^{-\frac{\Delta t}{\tau_k}} \psi_k^{n-1} + \frac{\Delta t}{2} \left( v_k^n + e^{-\frac{\Delta t}{\tau_k}} v_k^{n-1} \right)$ , abbreviation for calculations in a dispersive dielectric medium.		
$Q$	electric charge, As.		
$\rho$	reflection coefficient, dimensionless.		
$R'$	resistance per unit length of a transmission line, $\frac{\Omega}{m}$ .		
$R_S$	source impedance of resistive voltage source, $\Omega$ .		

*Acknowledgements.* We greatly appreciate the critical and constructive comments of C. Hübner and S. Schlaeger which helped us to qualitatively improve the manuscript.

We are most grateful to M. Laudien of Ansoft Inc. whose generous support with an HFSS<sup>TM</sup> license was essential for validating the analytical transmission line model and for benchmarking our TDR code.

Financial support of this work was provided in part by Deutsche Forschungsgemeinschaft (Project No. 1080-8/1&2).

Edited by: E. Zehe
