Abstract To study the influence of a linker rigidity and donor-acceptor properties, the P-CH₂-O-CHR- fragment in acyclic nucleoside phosphonates (e.g., acyclovir, tenofovir) was replaced by the P–CH₂–HN–C(O)– residue. The respective phosphonates were synthesized in good yields by coupling the straight chain of ω -aminophosphonates and nucleobase-derived acetic acids with EDC. Based on the ¹H and ¹³C NMR data, the unrestricted rotation within the methylene and 1,2-ethylidene linkers in phosphonates from series **a** and **b** was confirmed. For phosphonates containing 1,3-propylidene (series c) fragments, antiperiplanar disposition of the bulky O.O-diethylphosphonate and substituted amidomethyl groups was established. The synthesized ANPs $P-X-HNC(O)-CH_2B$ (X = CH₂, CH₂CH₂, CH₂-CH₂CH₂, CH₂OCH₂CH₂) appeared inactive in antiviral assays against a wide variety of DNA and RNA viruses at concentrations up to 100 µM while marginal antiproliferative activity (L1210 cells, $IC_{50} = 89 \pm 16 \mu M$ and HeLa cells, $IC_{50} = 194 \pm 19 \ \mu M$) was noticed for the analog derived from (5-fluorouracyl-1-yl)acetic acid and O,O-diethyl (2-aminoethoxy)methylphosphonate.

Introduction

The search for new compounds endowed with antiviral activity has been underway for decades. Several research groups have been active in this field, both in academia and pharmaceutical industry. Despite these efforts, for many viruses efficient drugs have not been yet discovered. In addition, anticancer drugs available so far exhibit limited applicability. The high mutation rate observed for some viruses makes the issue highly complex. Within medications applied to treat viral infections, acyclic nucleoside phosphonates (ANPs) play an important role [1-3]. The prototype of the acyclic nucleoside phosphonates (ANPs), (S)-HPMPA (3), was never commercialized but it gave rise to three marketed products [cidofovir (4), adefovir (1), and tenofovir (2)] that are often prescribed by physicians. So far known structural modifications of compounds 1-4 accomplished within a chain connecting nucleobase and phosphonic acid moieties did not lead to discovery of analogs having higher antiviral activity (Fig. 1).

Analysis of the mechanism of action of ANPs [3, 4] allows to conclude that within structures of newly designed

analogs of ANPs, the following fragments have to be installed: (1) a phosphonate unit (P–CH₂) which prevents enzymatic hydrolysis of the P–O bond present in natural phosphates, while being capable of further phosphorylation; (2) canonical nucleobases or their very close structurally heterocyclic systems to assure efficient interactions with the complementary nucleobases of the other polynucleotide chain; (3) a linker to adjust a distance between a nucleobase and a phosphorus atom which should contain four atoms considered optimal at this moment.

Taking into account high antiviral activity of compounds 1–4, one may be interested in specific interactions of oxygen lone pairs and also of the entire phosphonomethoxy (P–CH₂–O) fragment. The oxygen atom located within a P–CH₂–O–CHR– fragment can serve as a lone pair donor in intermolecular interactions, and single bonds connecting atoms in the linker ensure free rotation. To modify interactions of atoms located in the linker it is reasonable to consider replacing selected fragments of the linker for another moiety.

During studies on biological activity of peptides, replacements of the amide [-C(O)-NH-] residue for several isosteric fragments (including a methylene ether $[-CH_2-O-]$ moiety) are commonly applied [5–7]. This particular replacement allows to preserve steric conformity of both bonding systems but essentially influences donor-acceptor interactions and possibilities of a rotation around the specific bonds within the linker [completely free around the CH₂–O bond (11.3 kJ/mol—barrier to rotation) as

compared to the hindered around the C(O)–NH bond (88 kJ/mol—barrier to rotation)]. In general, this isosteric replacement diminishes affinity of modified peptides in comparison with the natural ones.

The proposed structural modification of ANPs 1–4 relies on the incorporation of a specific fragment which will be able to increase donor–acceptor interactions within the linker. In our first approach, the $[P-CH_2-O-CHR-]$ fragment will be replaced with the amide $[P-CH_2-HN-C(O)-]$ residue to provide amides 5 (Scheme 1). In addition, a part of the linker containing the amide bond becomes rigid and thus may influence the activity of modified ANPs.

Several decades ago, a concept of phosphonate peptide nucleic acids (PPNA) was introduced [8–11] and a variety of related monomers **6** were synthesized, however, limited to aminomethyl- and aminoethylphosphonate derivatives. Our interest in the synthesis of phosphonates of general formula **5** significantly extends structural diversity of potential new monomers **6** primarily in the aminoalkylphosphonate fragment.

Herein, we wish to describe our studies on the synthesis and the biological activity of the amides **5**. The synthetic strategy involves the formation of the amide bond from the respective acetic acid derivatives **8** and ω -aminophosphonates **7** (Scheme 1).

Results and discussion

To synthesize the first series of the amides 5, ω aminophosphonates **7a**–**7d** containing straight chain linkers were selected (Scheme 2). The ω -aminophosphonates **7a**– **7d** were prepared according to the described procedures [12–14]. Among them, aminomethylphosphonate **7a** was considered as the most important since it was later transformed into the analogs **17a–24a** in which nitrogen atoms (N1 or N9) in nucleobases and the phosphorus atom are separated by four bonds, thus providing compounds structurally closest to the drugs **1–4**.

are also known compounds and they were synthesized by alkylation of the respective nucleobases by chloro- or bromoacetic acid [15–19].

For future introduction of cytosine- and adenine-acetyl fragments, the protected acids 13 [20] and 15 [21] had to be prepared to significantly increase lipophilicity of the respective amides 21a-21d and 23a-23d. (2-Amino-6chloropurin-9-yl)acetic acid 16 [22] served as a precursor to guanine-decorated amides 25a-25d (Scheme 3).

A large number of coupling reagents have been developed for the efficient formation of the amide bond [23, 24] but only some of them proved useful in the peptide chemistry [25]. In search for the coupling system to be applied to our tasks, we were directed by studies of acylation of model secondary amines with (thymine-1yl)acetic acid (12) [26].

When the aminophosphonate 7a was reacted with the acid 12 in the presence of benzotriazol-1-yloxytris (dimethylamino)phosphonium hexafluorophosphate (BOP) [27], (benzotriazol-1-yloxy)tripyrrolidinophosphonium hexafluorophosphate (PyBOP) [28], N-[(dimethylamino)-1H-1,2,3-triazolo-[4,5-b]pyridin-1-ylmethylene]-N-methylmethanaminium hexafluorophosphate N-oxide (HATU) [29], and 1-[(1-(cyano-2-ethoxy-2-oxoethylideneaminooxy)-dimethylamino-morpholinomethylene)]methanaminium hexafluorophosphate (COMU) [29] with triethylamine or diethylisopropylamine as additives, the expected amide 20a could not be isolated from the complex reaction mixtures.

The same coupling was next performed with propylphosphonic anhydride $(T3P^{\mathbb{R}})$ [30] N-(3and dimethylaminopropyl)-N'-ethylcarbodiimide hydrochloride (EDC) [31, 32] to produce pure amide 20a [33] in acceptable yields (Table 1). As expected, microwave irradiation significantly accelerated the amide bond formation. In most cases, couplings of the aminophosphonates 7a-7d

with nucleobase-substituted acetic acids **9–16** in the presence of EDC proceeded almost quantitatively. However, the final products **17a–24d** were isolated in moderate yields since several crystallizations were necessary to remove the last traces of triethylamine hydrochloride.

The guanine-containing phosphonates **25a–25d** were prepared from the 6-chloropurine precursors **24a–24d** by hydrolysis in acidic medium (Scheme 3) [34].

Conformational analysis

We also aimed to study the conformational behavior of an acyclic linker connecting a phosphorus atom and the amide nitrogen for future structure–activity considerations. Free rotation around P–CH₂ and H₂C–NH bonds in phosphonates **17a–25a**, as depicted by **26a** in Fig. 2, is evidenced from the vicinal *H*NC*H* couplings of 5.9 Hz observed in the spectra of **21a** and **25a** taken in chloroform-*d* and DMSO-*d*₆, respectively. In solutions in these solvents as well as in methanol-*d*₄ *H*₂CP are equivalent since they always appeared as a one doublet from two-bond HP coupling of 11.8 Hz.

Structure **26b** (Fig. 2) summarizes conformational flexibility of phosphonates **17b–25b** which is proved by the observation of the vicinal H_2C-CH_2 couplings of 7.6 Hz.

Since ¹³C NMR spectra of phosphonates **17c–25c** showed large values (18.1–19.6 Hz) of vicinal PCCC couplings, the antiperiplanar disposition of the *P*–CC–*CH*₂ groups is proposed and represented by the Newman projection **26c**.

Fig. 2 Conformations of phosphonates discussed in this paper

Although significant values (11.0-12.1 Hz) were observed in the ¹³C NMR spectra of phosphonates **17d**–**25d** for vicinal PCOC couplings, they cannot be applied with confidence to discuss conformational behavior of the -CH₂OCH₂CH₂- linkage since the angular dependence within a P-C-O-C framework has not yet been established.

Antiviral activity

All phosphonates 17–25 were evaluated for inhibitory activity against a wide variety of DNA and RNA viruses, using the following cell-based assays: (a) human embryonic lung (HEL) cells: herpes simplex virus-1 (KOS strain), herpes simplex virus-2 (G strain), thymidine kinase-deficient (acyclovir resistant) herpes simplex virus-1 (TK⁻ KOS ACV^r strain), vaccinia virus, adenovirus-2, vesicular stomatitis virus, cytomegalovirus (AD-169 strain and Davis strain), varicella-zoster virus (TK⁺ VZV strain and TK⁻ VZV strain); (b) HeLa cell cultures: vesicular stomatitis virus. Coxsackie virus B4 and respiratory syncytial virus; (c) Vero cell cultures: parainfluenza-3 virus, reovirus-1, Sindbis virus, Coxsackie virus B4, Punta Toro virus, yellow fever virus; (d) CrFK cell cultures: feline corona virus (FIPV) and feline herpes virus (FHV); (e) MDCK cell cultures: influenza A virus (H1N1 and H3N2 subtypes) and influenza B virus. Ganciclovir, cidoacyclovir, brivudine, zalcitabine, zanamivir, fovir. alovudine, amantadine, rimantadine, ribavirin, dextran sulfate (molecular weight 10,000, DS-10000), mycophenolic acid, Hippeastrum hybrid agglutinin (HHA) and Urtica dioica agglutinin (UDA) were used as the reference compounds. The antiviral activity was expressed as the EC_{50} : the compound concentration required to reduce virus plaque formation (VZV) by 50% or to reduce virus-induced cytopathogenicity by 50% (other viruses). None of the tested compounds showed appreciable antiviral activity toward any of the tested DNA and RNA viruses at concentrations up to 100 µM, nor affected cell morphology of HEL, HeLa, Vero, MDCL, and CrFK cells.

Cytostatic activity

The 50% cytostatic inhibitory concentration (IC₅₀) causing a 50% decrease in cell proliferation was determined against

Fig. 3 Active derivatives of 5-fluorouracil

murine leukemia L1210, human lymphocyte CEM, human cervix carcinoma HeLa, and human dermal microvascular endothelial cells (HMEC-1).

Among all tested compounds, only phosphonate **18d** showed slight antiproliferative activity toward L1210 ($IC_{50} = 89 \pm 16 \mu M$) and HeLa cells ($IC_{50} = 194 \pm 19 \mu M$) and thus enlarges a collection of 5-fluorouracil derivatives which together with the parent compound have been widely clinically applied in therapies of various cancers [35]. Furthermore, the closest structural analog of **18d** (compound **18e**) was found active in vitro against L1210 cells at concentration of 15 μM [36] (Fig. 3).

Conclusion

Replacement of the P-CH₂-O-CHR- fragment in ANPs (e.g., acyclovir, tenofovir) by the P-CH₂-HN-C(O)residue was introduced to study the influence of a linker rigidity and changes in donor-acceptor properties. To elaborate an appropriate synthetic methodology, a series of the 36 respective phosphonates as O,O-diethyl esters was prepared in good yields by the EDC-induced coupling of the straight chain ω -aminophosphonates and nucleobasederived acetic acids. Besides the rigidity of the amide bond based on the ¹H and ¹³C NMR data, it was concluded that the unrestricted rotation within the methylene (series a) and 1,2-ethylidene (series b) linkers takes place while for phosphonates containing 1,3-propylidene (series c) fragments antiperiplanar disposition of the bulky O,Odiethylphosphonate and substituted amidomethyl groups was observed. The phosphonates 17a-25d appeared inactive in antiviral assays against a wide variety of DNA and RNA viruses at concentrations up to 100 µM. Marginal antiproliferative activity (L1210, IC₅₀ = $89 \pm 16 \mu M$ and HeLa, $IC_{50} = 194 \pm 19 \mu M$) was noticed for the phosphonate 18d derived from (5-fluorouracyl-1-yl)acetic acid and *O*,*O*-diethyl (2-aminoethoxy)methylphosphonate. Studies on the analogous phosphonates containing functionalized linkages are currently ongoing in our laboratory and the most active diethyl esters will be transformed into

phosphonates [37].

¹H NMR spectra were recorded in CD₃OD, CDCl₃, or DMSO- d_6 on the following spectrometers: Varian Gemini 2000BB (200 MHz) and Bruker Avance III (600 MHz) with TMS as internal standard. ¹³C NMR spectra were recorder for CD₃OD, CDCl₃, or DMSO- d_6 solution on the Bruker Avance III at 151.0 MHz. ³¹P NMR spectra were performed on the Varian Gemini 2000BB at 81.0 MHz or on Bruker Avance III at 243.0 MHz. IR spectral data were measured on a Bruker Alpha-T FT-IR spectrometer. Melting points were determined on a Boetius apparatus. Elemental analyses were performed by Microanalytical Laboratory of this Faculty on Perkin Elmer PE 2400 CHNS analyzer and their results were found to be in good agreement (±0.3%) with the calculated values.

The following absorbents were used: column chromatography, Merck silica gel 60 (70–230 mesh); analytical TLC, Merck TLC plastic sheets silica gel 60 F_{254} . TLC plates were developed in chloroform–methanol solvent systems. Visualization of spots was effected with iodine vapors. All solvents were purified by methods described in the literature.

Synthesis of amides 17-24

General procedure A

A solution of 0.100 g aminophosphonate **7a** (0.598 mmol) in 2 cm³ DMF containing 0.100 g (thymine-1-yl)acetic acid (**12**, 0.544 mmol) was cooled to 0 °C and 0.152 cm³ TEA (1.09 mmol) followed by a 0.481 cm³ of a 50% solution of T3P[®] in DMF (0.816 mmol) were added. The reaction mixture was stirred at room temperature for 24 h, concentrated in vacuo and treated with 5 cm³ water. A solid was filtered off, air dried, and subjected to chromatography on a silica gel column with chloroform–methanol mixtures (20:1, 10:1 v/v) to give pure compound **20a** (0.072 g, 40% yield) as a white powder.

General procedure B

To a solution of aminophosphonates 7a-7d (1.00 mmol) in 2 cm³ DMF or chloroform the respective acetic acids 9-16 (1.00 mmol), EDC × HCl (1.00 mmol), and TEA (1.00 mmol) were added. The reaction mixture was stirred at room temperature for 48–72 h and then concentrated in vacuo. The residue was chromatographed on a silica gel column with chloroform–methanol mixtures and crystal-lized from the appropriate solvents.

General procedure C

To a solution of aminophosphonates 7a-7d (1.00 mmol) in 2 cm³ chloroform the respective acetic acids 9-16 (1.00 mmol), EDC × HCl (1.00 mmol), and TEA (1.00 mmol) were added. The reaction mixture was irradiated (100 W) at 35 °C for the specified time (15 min-3 h) and then concentrated in vacuo. The residue was chromatographed on a silica gel column with chloroformmethanol mixtures and crystallized from the appropriate solvents.

Diethyl [2-(3,4-*dihydro*-2,4-*dioxopyrimidin*-1(2H)-yl)acetamido]methylphosphonate (**17a**, C₁₁H₁₈N₃O₆P)

The crude product obtained from 0.100 g diethyl 2aminomethylphosphonate (7a, 0.60 mmol) and 0.097 g (uracil-1-yl)acetic acid (9, 0.60 mmol) in the presence of 0.115 g EDC \times HCl (0.60 mmol) and 0.083 cm³ TEA (0.60 mmol) according to the general procedure B was chromatographed with chloroform-methanol mixtures (50:1, 20:1 v/v) to give pure compound 17a (0.106 g, 55% yield) as a white powder. M.p.: 215–217 °C; IR (KBr): $\bar{v} = 3254$, 3058, 2997, 2882, 2831, 1703, 1679, 1259, 1193, 1031 cm⁻¹; ¹H NMR (200 MHz, CD₃OD): $\delta = 7.56$ (d, ${}^{3}J = 7.9$ Hz, 1H, HC6), 5.71 (d, ${}^{3}J = 7.9$ Hz, 1H, HC5), 4.51 (d, ${}^{3}J = 1.4$ Hz, 2H, C(O)CH₂), 4.26–4.11 (m, 4H, $2 \times POCH_2CH_3$, 3.78 (d, $^2J = 11.8$ Hz, 2H, PCH₂N), 1.37 (t, J = 7.0 Hz, 6H, $2 \times POCH_2CH_3$) ppm; ¹³C NMR (151 MHz, CD₃OD): $\delta = 167.92$ (d, J = 3.7 Hz), 165.38, 151.36, 146.37, 100.85, 62.79 (d, J = 6.5 Hz, POC), 49.56, 34.23 (d, J = 158.5 Hz, PC), 15.28 (d, J = 5.8 Hz, POCC) ppm; ³¹P NMR (243 MHz, CD₃OD): $\delta = 23.6$ ppm.

Diethyl 2-[2-(3,4-dihydro-2,4-dioxopyrimidin-1(2H)-yl)acetamido]ethylphosphonate (**17b**, C₁₂H₂₀N₃O₆P)

The crude product obtained from 0.100 g diethyl 2aminoethylphosphonate (7b, 0.550 mmol) and 0.094 g (uracil-1-yl)acetic acid (9, 0.55 mmol) in the presence of 0.105 g EDC \times HCl (0.550 mmol) and 0.077 cm³ TEA (0.55 mmol) according to the general procedure B was chromatographed with chloroform-methanol mixtures (50:1, 20:1 v/v) to give pure compound **17b** (0.095 g, 52% yield) as a white powder. M.p.: 138-140 °C; IR (KBr): $\bar{v} = 3340$, 2986, 2953, 2896, 2826, 1696, 1673, 1236, 1024 cm⁻¹; ¹H NMR (600 MHz, CD₃OD): $\delta = 7.52$ (d, ${}^{3}J = 7.9$ Hz, 1H, HC6), 5.70 (d, ${}^{3}J = 7.9$ Hz, 1H, HC5), 4.43 (s, 2H, C(O)CH₂), 4.18-4.10 (m, 4H, $2 \times \text{POC}H_2\text{CH}_3$, 3.48 (dt, J = 12.3 Hz, J = 7.6 Hz, 2H, PCH_2CH_2), 2.10 (dt, J = 15.3 Hz, J = 7.6 Hz, 2H, PCH_2), 1.36 (t, J = 7.1 Hz, 6H, 2 × POCH₂CH₃) ppm; ¹³C NMR (151 MHz, CD₃OD): $\delta = 167.92$, 165.38, 151.49, 146.38, 100.95, 62.09 (d, J = 6.5 Hz, POC), 49.81, 33.41, 24.87 (d, J = 139.0 Hz, PC), 15.31 (d, J = 6.2 Hz, POCC) ppm;³¹P NMR (243 MHz, CD₃OD): $\delta = 29.34$ ppm.

Antiviral activity assays

The compounds were evaluated against the following viruses: herpes simplex virus type 1 (HSV-1) strain KOS, herpes simplex virus-2 strain G, thymidine kinase-deficient (TK⁻) HSV-1 KOS strain resistant to ACV (ACV^r), adenovirus-2, vesicular stomatitis virus, varicella-zoster virus (VZV) strain Oka, TK⁻ VZV strain 07-1, human cytomegalovirus (HCMV) strains AD-169 and Davis, feline herpes virus (FHV), vaccinia virus Lederle strain, respiratory syncytial virus (RSV) strain Long, vesicular stomatitis virus (VSV), feline coronovirus (FIPV), Coxsackie B4, Parainfluenza 3, Influenza virus A (subtypes H1N1, H3N2), influenza virus B, Reovirus-1, Sindbis, Reovirus-1, Punta Toro, yellow fever virus. The antiviral, other than anti-HIV, assays were based on inhibition of virus-induced cytopathicity or plaque formation in human embryonic lung (HEL) fibroblasts, African green monkey cells (Vero), human epithelial cells (HeLa), Crandell-Rees feline kidney cells (CRFK) or Madin-Darby canine kidney cells (MDCK). Confluent cell cultures in microtiter 96-well

plates were inoculated with 100 CCID₅₀ of virus (1 CCID₅₀ being the virus dose to infect 50% of the cell cultures) or with 20 plaque forming units (PFU) (VZV) in the presence of varying concentrations of the test compounds. Viral cytopathicity or plaque formation was recorded as soon as it reached completion in the control virus-infected cell cultures that were not treated with the test compounds. Antiviral activity was expressed as the EC_{50} or compound concentration required to reduce virus-induced cytopathogenicity or viral plaque formation by 50%. Cytotoxicity of the test compounds was expressed as the minimum cytotoxic concentration (MCC) or the compound concentration that caused a microscopically detectable alteration of cell morphology.

Cytostatic activity assays

All assays were performed in 96-well microtiter plates. To each well were added $(5-7.5) \times 10^4$ tumor cells and a given amount of the test compound. The cells were allowed to proliferate for 48 h (murine leukemia L1210 cells) or 72 h (human lymphocytic CEM and human cervix carcinoma HeLa cells) at 37 °C in a humidified CO₂-controlled atmosphere. At the end of the incubation period, the cells were counted in a Coulter counter. The IC₅₀ (50% inhibitory concentration) was defined as the concentration of the compound that inhibited cell proliferation by 50%.

Acknowledgements Financial supports from the National Science Centre (Grant UMO-2013/09/B/NZ7/00729—synthetic part of the project) and the KU Leuven (GOA 15/19 TBA—biological screening) are gratefully acknowledged. The Faculty of Pharmacy authors wish to express their gratitude to Mrs. Jolanta Płocka and Mrs. Małgorzata Pluskota for excellent technical assistance. Special thanks are forwarded to the Rega Institute collaborators: Mrs. Leentje Persoons, Mrs. Frieda De Meyer, Mrs. Ellen De Waegenaere and Mrs. Lizette van Berckelaer.
