The aim of this work is to study the semidiscrete finite element discretization for a class of semilinear parabolic integrodifferential optimal control problems. We derive a posteriori error estimates in $L^2(J; L^2(\Omega))$ -norm and $L^2(J; H^1(\Omega))$ -norm for both the control and coupled state approximations. Such estimates can be used to construct reliable adaptive finite element approximation for semilinear parabolic integrodifferential optimal control problem. Furthermore, we introduce an adaptive algorithm to guide the mesh refinement. Finally, a numerical example is given to demonstrate the theoretical results.

1. Introduction

With the advances of scientific computing, optimal control problems are now widely used in multidisciplinary applications such as physical, biological, medicine, engineering design, finance, fluid mechanics, and socioeconomic systems. As a result, more and more people will benefit greatly by learning to solve the optimal control problems numerically. Realizing such growing needs, books and papers on optimal control put more weight on numerical methods.

In modeling a wide range of problems for physical, economic, and social processes, optimal control problems described by integrodifferential equations play an important role. Parabolic integrodifferential optimal control problems are very important model in engineering numerical simulation, for example, biology mechanics, nuclear reaction dynamics, heat conduction in materials with memory, viscoelasticity, and so forth. Finite element approximation of optimal control problems has a very important status in the numerical methods for these problems. The finite element approximation of optimal control problem by piecewise constant functions was well investigated by Falk [1] and Geveci [2]. The finite element methods for semilinear elliptic optimal control problems were discussed by Casas et al. in [3]. In [4],

the author studied the finite element discretization for a class of quadratic boundary optimal control problems governed by nonlinear elliptic equations and obtained a posteriori error estimates for the coupled state and control approximation. Many introductions about the numerical computation method for optimal control problems can be found in [5–8].

As one of important kinds of optimal control problems, parabolic integrodifferential optimal control problem is widely used in scientific and engineering computing. The literature in this aspect was huge, see; for example, [9]. In [10], Brunner and Yan analyzed finite element Galerkin discretization for a class of optimal control problems governed by integral equations and integrodifferential equations and derived a priori error estimates and a posteriori error estimators for the approximation solutions.

Adaptive finite element method is the most important method to boost accuracy of the finite element discretization. It ensures a higher density of nodes in certain area of the given domain, where the solution is discontinuous or more difficult to approximate, using an a posteriori error indicator. A posteriori error estimates are computable quantities in terms of the discrete solution and they measure the actual discrete errors without the knowledge of exact solutions. They are essential in designing algorithms for mesh which

equidistribute the computational effort and optimize the computation. The literature in this was huge. In [11], the authors presented an a posteriori error analysis for finite element approximation of distributed convex elliptic optimal control problems. They derived a posteriori error estimates for the coupled state and control approximations. Such estimates can be used to construct reliable adaptive finite element approximation schemes for control problems. In [12], Verfürth gave a general framework for deriving a posteriori error estimates for approximate solutions of nonlinear elliptic equations. He obtained a posteriori error estimates, which can easily be computed from the given data of the problem and the computed numerical solution and which give global upper and local lower bounds on the error of the numerical solution. Some of techniques directly relevant to our work can be found in [11, 12]. Recently, in [13–16], we derived a priori error estimates and a posteriori error estimates for optimal control problems using mixed finite element methods. Although a posteriori error estimates of finite element approximation were widely used in numerical simulations, they have not yet been utilized in nonlinear parabolic integrodifferential optimal control problem.

In this paper, we adopt the standard notation $W^{m,p}(\Omega)$ for Sobolev spaces on Ω with a norm $\|\cdot\|_{m,p}$ given by $\|v\|_{m,p}^p = \sum_{|\alpha|\leq m} \|D^\alpha v\|_{L^p(\Omega)}^p$ and a seminorm $|\cdot|_{m,p}$ given by $|v|_{m,p}^p = \sum_{|\alpha|=m} \|D^\alpha v\|_{L^p(\Omega)}^p$. We set $W_0^{m,p}(\Omega) = \{v \in W^{m,p}(\Omega) : v|_{\partial\Omega} = 0\}$. For $p = 2$, we denote $H^m(\Omega) = W^{m,2}(\Omega)$, $H_0^m(\Omega) = W_0^{m,2}(\Omega)$, and $\|\cdot\|_m = \|\cdot\|_{m,2}$, $\|\cdot\| = \|\cdot\|_{0,2}$. We denote by $L^s(0, T; W^{m,p}(\Omega))$ the Banach space of all L^s integrable functions from J to $W^{m,p}(\Omega)$ with norm $\|v\|_{L^s(J; W^{m,p}(\Omega))} = \left(\int_0^T \|v\|_{W^{m,p}(\Omega)}^s dt\right)^{1/s}$ for $s \in [1, \infty)$, and the standard modification for $s = \infty$. The details can be found in [9].

In this paper, we derive a posteriori error estimates for a class of semilinear parabolic integrodifferential optimal control problems. To the best of our knowledge in the context of semilinear parabolic integrodifferential optimal control problems, these estimates are new. We consider the following semilinear parabolic integrodifferential optimal control problems:

$$\min_{u(t) \in K \subset U} \left\{ \int_0^T \left(\frac{1}{2} \|y - y_0\|^2 + \frac{\alpha}{2} \|u\|^2 \right) dt \right\} \quad (1)$$

subject to the state equation

$$\begin{aligned} y_t - \operatorname{div}(A \nabla y(x, t)) \\ - \int_0^t \operatorname{div}(\psi(t, \tau) \nabla y(x, \tau)) d\tau + \phi(y) \\ = f + Bu, \quad x \in \Omega, t \in J, \\ y(x, t) = 0, \quad x \in \partial\Omega, t \in J, \\ y(x, 0) = y_0(x), \quad x \in \Omega, \end{aligned} \quad (2)$$

where the bounded open set $\Omega \subset \mathbb{R}^2$ is 2 regular convex polygon with boundary $\partial\Omega$, $J = (0, T]$, $f \in L^2(\Omega)$, $\psi =$

$\psi(x, t, \tau) = \psi_{i,j}(x, t, \tau)_{2 \times 2} \in C^\infty(0, T; L^2(\bar{\Omega}))^{2 \times 2}$, $y_0 \in H^1(\Omega)$, α is a positive constant, and B is a continuous linear operator from K to $L^2(\Omega)$. For any $R > 0$, the function $\phi(\cdot) \in W^{2,\infty}(-R, R)$, $\phi'(y) \in L^2(\Omega)$ for any $y \in L^2(J; H_0^1(\Omega))$, and $\phi'(y) \geq 0$. We assume that the coefficient matrix $A(x) = (a_{i,j}(x))_{2 \times 2} \in (W^{1,\infty}(\Omega))^{2 \times 2}$ is a symmetric positive definite matrix and there is a constant $c > 0$ satisfying for any vector $\mathbf{X} \in \mathbb{R}^2$, $\mathbf{X}^t \mathbf{A} \mathbf{X} \geq c \|\mathbf{X}\|_{\mathbb{R}^2}^2$. Here, K denotes the admissible set of the control variable defined by

$$K = \left\{ u(x, t) \in U = L^2(J; L^2(\Omega)) : u(x, t) \geq 0, t \in J \right\}. \quad (3)$$

Assume that there are constants c and C , such that for all t and τ in $[0, T]$:

$$a(z, z) \geq c \|z\|_{1,\Omega}^2, \quad \forall z \in V, \quad (4)$$

$$|a(z, w)| \leq C \|z\|_{1,\Omega} \cdot \|w\|_{1,\Omega}, \quad \forall z, w \in V, \quad (5)$$

$$|\psi(t, \tau; z, w)| \leq C \|z\|_{1,\Omega} \cdot \|w\|_{1,\Omega}, \quad \forall z, w \in V. \quad (6)$$

The plan of this paper is as follows. In the next section, we present the finite element discretization for semilinear parabolic integrodifferential optimal control problems. A posteriori error estimates are established for the optimal control problems in Section 3. In Section 4, we introduce an adaptive algorithm to guide the mesh refinement. In Section 5, a numerical example is given to demonstrate our theoretical results. Finally, we analyze the conclusion and future work in Section 6.

2. Finite Elements for Integrodifferential Optimal Control

We will now describe the finite element discretization of semilinear parabolic integrodifferential optimal control problems (1)-(2). Let $V = H_0^1(\Omega)$ and $W = L^2(\Omega)$. Let

$$a(y, w) = \int_\Omega (A \nabla y) \cdot \nabla w, \quad \forall y, w \in V,$$

$$\psi(t, \tau; z, w) = (\psi(t, \tau) \nabla z, \nabla w), \quad \forall z, w \in V \times V, \quad (7)$$

$$(u, v) = \int_\Omega uv, \quad \forall (u, v) \in W \times W,$$

$$(f_1, f_2) = \int_\Omega f_1 f_2, \quad \forall (f_1, f_2) \in W \times W.$$

Then, the semilinear parabolic integrodifferential optimal control problems (1)-(2) can be restated as

$$\min_{u(t) \in K} \left\{ \int_0^T \left(\frac{1}{2} \|y - y_0\|^2 + \frac{\alpha}{2} \|u\|^2 \right) dt \right\} \quad (8)$$

subject to

$$\begin{aligned} & (y_t, w) + a(y, w) + \int_0^t \psi(t, \tau; y(\tau), w) d\tau + (\phi(y), w) \\ & = (f + Bu, w), \quad \forall w \in V, t \in J, \\ & y(x, 0) = y_0(x), \quad x \in \Omega, \end{aligned} \tag{9}$$

where the inner product in $L^2(\Omega)$ or $L^2(\Omega)^2$ is indicated by (\cdot, \cdot) . From Yanik and Fairweather [17], we know that the above weak form has at least one solution in $y \in W(0, T) = \{w \in L^2(0, T; H^1(\Omega)), w'_t \in L^2(0, T; H^{-1}(\Omega))\}$.

It is well known (see, e.g., [11]) that the optimal control problem has a solution (y, u) , and if a pair (y, u) is the solution of (8)-(9), then there is a costate $p \in V$ such that triplet (y, p, u) satisfies the following optimality conditions:

$$\begin{aligned} & (y_t, w) + a(y, w) \\ & + \int_0^t \psi(t, \tau; y(\tau), w) d\tau + (\phi(y), w) \end{aligned} \tag{10}$$

$$\begin{aligned} & = (f + Bu, w), \quad \forall w \in V, \\ & y(x, 0) = y_0(x), \quad x \in \Omega, \end{aligned} \tag{11}$$

$$\begin{aligned} & - (p_t, w) + a(q, p) + \int_t^T \psi(\tau, t; q, p(\tau)) d\tau + (\phi'(y) p, q) \\ & = (y - y_0, q), \quad \forall q \in V, \end{aligned} \tag{12}$$

$$p(x, T) = 0, \quad x \in \Omega, \tag{13}$$

$$\int_0^T (\alpha u + B^* p, v - u)_V dt \geq 0, \quad \forall v \in K, \tag{14}$$

where B^* is the adjoint operator of B . In the rest of the paper, we will simply write the product as (\cdot, \cdot) whenever no confusion should be caused.

Let us consider the finite element approximation of the optimal control problem (8)-(9). Again here we consider only n -simplex elements and conforming finite elements.

Let \mathcal{T}^h be regular partition of Ω . Associated with \mathcal{T}^h is a finite dimensional subspace V_h of $C(\bar{\Omega})$, such that $\chi|_\tau$ are polynomials of m -order ($m \geq 1$) for all $\chi \in V_h$ and $\tau \in \mathcal{T}^h$. It is easy to see that $V_h \subset V$. Let h_τ denote the maximum diameter of the element τ in \mathcal{T}^h , $h = \max_{\tau \in \mathcal{T}^h} \{h_\tau\}$.

Due to the limited regularity of the optimal control u in general, there will be no advantage in considering higher-order finite element spaces for the control. So, we only consider the piecewise constant finite element space for the approximation of the control, though higher-order finite element spaces will be used to approximate the state and the costate. Let $P_0(\tau)$ denote all the 0-order polynomial over τ . Therefore, we take $K_h = \{u \in K : u(x, t)|_\tau \in P_0(\tau)\}$. In addition, C or c denotes a general positive constant independent of h .

By the definition of finite element subspace, the finite element discretization of (8)-(9) is as follows: compute $(y_h, u_h) \in V_h \times K_h$ such that

$$\min_{u_h \in K_h} \left\{ \int_0^T \left(\frac{1}{2} \|y_h - y_0\|^2 + \frac{\alpha}{2} \|u_h\|^2 \right) dt \right\} \tag{15}$$

$$(y_{ht}, w_h) + a(y_h, w_h) + \int_0^t \psi(t, \tau; y_h(\tau), w_h) d\tau \tag{16}$$

$$\begin{aligned} & + (\phi(y_h), w_h) = (f + Bu_h, w_h), \\ & y_h(x, 0) = y_0^h(x), \quad x \in \Omega, \end{aligned} \tag{17}$$

where $w_h \in V_h$, $y_0^h \in V_h$ is an approximation of y_0 .

Again, it follows that the optimal control problems (15)–(17) have a solution (y_h, u_h) , and if a pair (y_h, u_h) is the solution of (15)–(17), then there is a costate $p_h \in V_h$ such that triplet (y_h, p_h, u_h) satisfies the following optimality conditions:

$$(y_{ht}, w_h) + a(y_h, w_h) + \int_0^t \psi(t, \tau; y_h(\tau), w_h) d\tau \tag{18}$$

$$\begin{aligned} & + (\phi(y_h), w_h) = (f + Bu_h, w_h), \\ & y_h(x, 0) = y_0^h(x), \quad x \in \Omega, \end{aligned} \tag{19}$$

$$- (p_{ht}, w_h) + a(q_h, p_h) + \int_t^T \psi(\tau, t; q_h, p_h(\tau)) d\tau \tag{20}$$

$$\begin{aligned} & + (\phi'(y_h) p_h, q_h) = (y_h - y_0, q_h), \\ & p_h(x, T) = 0, \quad x \in \Omega, \end{aligned} \tag{21}$$

$$\int_0^T (\alpha u_h + B^* p_h, v_h - u_h) dt \geq 0, \tag{22}$$

where $w_h, q_h \in V_h$, and $v_h \in K_h$.

In the rest of the paper, we will use some intermediate variables. For any control function $u_h \in K$, we first define the state solution $(y(u_h), p(u_h))$ satisfying

$$\begin{aligned} & (y_t(u_h), w) + a(y(u_h), w) \\ & + \int_0^t \psi(t, \tau; y(u_h)(\tau), w) d\tau \end{aligned} \tag{23}$$

$$\begin{aligned} & + (\phi(y(u_h)), w) = (f + Bu_h, w), \\ & \forall w \in V, \quad y(u_h)(x, 0) = y_0(x), \quad x \in \Omega, \end{aligned} \tag{24}$$

$$\begin{aligned} & - (p_t(u_h), q) + a(q, p(u_h)) + \int_t^T \psi(\tau, t; q, p(u_h)(\tau)) d\tau \\ & + (\phi'(y(u_h)) p(u_h), q) \end{aligned} \tag{25}$$

$$\begin{aligned} & = (y(u_h) - y_0, q), \quad \forall q \in V, \quad p(u_h)(x, T) = 0, \quad x \in \Omega. \end{aligned} \tag{26}$$

Now, we restate the following well-known estimates in [9].

Lemma 1. Let $\hat{\pi}_h$ be the Clément-type interpolation operator defined in [9]. Then for any $v \in H^1(\Omega)$ and all element τ ,

$$\begin{aligned} & \|v - \hat{\pi}_h v\|_{L^2(\tau)} + h_\tau \|\nabla(v - \hat{\pi}_h v)\|_{L^2(\tau)} \\ & \leq Ch_\tau \sum_{\tau' \cap \bar{\tau} \neq \emptyset} |v|_{L^2(\tau')}, \end{aligned} \quad (27)$$

$$\|v - \hat{\pi}_h v\|_{L^2(l)} \leq Ch_l^{1/2} \sum_{l \subset \tau'} |\nabla v|_{L^2(\tau')},$$

where l is the edge of the element.

For $\varphi \in W_h$, we will write

$$\begin{aligned} \phi(\varphi) - \phi(\rho) &= -\bar{\phi}'(\varphi)(\rho - \varphi) \\ &= -\phi'(\rho)(\rho - \varphi) + \bar{\phi}''(\varphi)(\rho - \varphi)^2, \end{aligned} \quad (28)$$

where

$$\begin{aligned} \bar{\phi}'(\varphi) &= \int_0^1 \phi'(\varphi + s(\rho - \varphi)) ds, \\ \bar{\phi}''(\varphi) &= \int_0^1 (1-s) \phi''(\rho + s(\varphi - \rho)) ds \end{aligned} \quad (29)$$

are bounded functions in $\bar{\Omega}$ [12].

3. A Posteriori Error Estimates

In this section, we will obtain a posteriori error estimates for semilinear parabolic integrodifferential optimal control problems. Firstly, we estimate the error $\|u - u_h\|_{L^2(J;L^2(\Omega))}$.

For given $u \in K$, let M be the inverse operator of the state equation (10), such that $y(u) = MBu$ is the solution of the state equation (10). Similarly, for given $u_h \in K_h$, $y_h(u_h) = M_h B u_h$ is the solution of the discrete state equation (16). Let

$$\begin{aligned} S(u) &= \frac{1}{2} \|MBu - y_0\|^2 + \frac{\alpha}{2} \|u\|^2, \\ S_h(u_h) &= \frac{1}{2} \|M_h B u_h - y_0\|^2 + \frac{\alpha}{2} \|u_h\|^2. \end{aligned} \quad (30)$$

It is clear that S and S_h are well defined and continuous on K and K_h . Also the functional S_h can be naturally extended on K . Then (8) and (15) can be represented as

$$\min_{u \in K} \{S(u)\}, \quad (31)$$

$$\min_{u_h \in K_h} \{S_h(u_h)\}. \quad (32)$$

It can be shown that

$$\begin{aligned} (S'(u), v) &= (\alpha u + B^* p, v), \\ (S'(u_h), v) &= (\alpha u_h + B^* p(u_h), v), \\ (S'_h(u_h), v) &= (\alpha u_h + B^* p_h, v), \end{aligned} \quad (33)$$

where $p(u_h)$ is the solution of (23)–(25).

In many applications, $S(\cdot)$ is uniformly convex near the solution u (see, e.g., [18]). The convexity of $S(\cdot)$ is closely related to the second-order sufficient conditions of the control problems, which was assumed in many studies on numerical methods of the problems. If $S(\cdot)$ is uniformly convex, then there is a $c > 0$, such that

$$\int_0^T (S'(u) - S'(u_h), u - u_h) dt \geq c \|u - u_h\|_{L^2(J;L^2(\Omega))}^2, \quad (34)$$

where u and u_h are the solutions of (31) and (32), respectively. We will assume the above inequality throughout this paper.

Let $p(u_h)$ be the solution of (23)–(25); we establish the following error estimate.

Theorem 2. Let u and u_h be the solutions of (31) and (32), respectively. Assume that $K_h \subset K$. In addition, assume that $(S'_h(u_h))|_\tau \in H^s(\tau)$, for all $\tau \in \mathcal{T}_h$, ($s = 0, 1$), and there is a $v_h \in K_h$ such that

$$\left| (S'_h(u_h), v_h - u) \right| \leq C \sum_{\tau \in \mathcal{T}_h} h_\tau \|S'_h(u_h)\|_{H^s(\tau)} \|u - u_h\|_{L^2(\tau)}^s. \quad (35)$$

Then, one has

$$\|u - u_h\|_{L^2(J;L^2(\Omega))}^2 \leq C \eta_1^2 + C \|p_h - p(u_h)\|_{L^2(J;H^1(\Omega))}^2, \quad (36)$$

where

$$\eta_1^2 = \int_0^T \sum_{\tau \in \mathcal{T}_h} h_\tau^{1+s} \|\alpha u_h + B^* p_h\|_{H^s(\tau)}^{1+s} dt. \quad (37)$$

Proof. It follows from (31) and (32) that

$$\int_0^T (S'(u), u - v) \leq 0, \quad \forall v \in K, \quad (38)$$

$$\int_0^T (S'_h(u_h), u_h - v_h) \leq 0, \quad \forall v_h \in K_h \subset K. \quad (39)$$

Then it follows from (35), (39), and the Schwartz inequality, that

$$\begin{aligned} & c \|u - u_h\|_{L^2(J;L^2(\Omega))}^2 \\ & \leq \int_0^T (S'(u) - S'(u_h), u - u_h) dt \\ & \leq - \int_0^T (S'(u_h), u - u_h) dt \\ & = \int_0^T \left\{ (S'_h(u_h), u_h - u) \right. \\ & \quad \left. + (S'_h(u_h) - S'(u_h), u - u_h) \right\} dt \end{aligned}$$

$$\begin{aligned}
 &\leq \int_0^T \left\{ (S'_h(u_h), v_h - u) \right. \\
 &\quad \left. + (S'_h(u_h) - S'(u_h), u - u_h) \right\} dt \\
 &\leq C \int_0^T \left\{ \sum_{\tau \in \mathcal{T}_h} h_\tau^{1+s} \|S'_h(u_h)\|_{H^s(\tau)}^{1+s} \right. \\
 &\quad \left. + \|S'_h(u_h) - S'(u_h)\|_{L^2(\Omega)}^2 \right\} dt \\
 &\quad + \frac{c}{2} \|u - u_h\|_{L^2(J; L^2(\Omega))}^2.
 \end{aligned} \tag{40}$$

It is not difficult to show that

$$S'_h(u_h) = \alpha u_h + B^* p_h, \quad S'(u_h) = \alpha u_h + B^* p(u_h), \tag{41}$$

where $p(u_h)$ is defined in (23)–(26). Thanks to (11), it is easy to derive

$$\begin{aligned}
 &\int_0^T \|S'_h(u_h) - S'(u_h)\|_{L^2(\Omega)} dt \\
 &= \int_0^T \|B^*(p_h - p(u_h))\|_{L^2(\Omega)} dt \\
 &\leq C \|p_h - p(u_h)\|_{L^2(J; L^2(\Omega))} \\
 &\leq C \|p_h - p(u_h)\|_{L^2(J; H^1(\Omega))}.
 \end{aligned} \tag{42}$$

Then, by the estimates (40) and (42), we can prove the requested result (36). \square

Now, we estimate the error $\|y(u_h) - y_h\|_{L^2(J; H^1(\Omega))}$.

Theorem 3. *Let $(y(u_h), p(u_h))$ and (y_h, p_h) be the solutions of (23)–(26) and (18)–(22), respectively. Then*

$$\|y(u_h) - y_h\|_{L^2(J; H^1(\Omega))}^2 \leq C \sum_{i=2}^4 \eta_i^2, \tag{43}$$

where

$$\begin{aligned}
 \eta_2^2 = &\int_0^T \sum_{\tau \in \mathcal{T}_h} h_\tau^2 \int_\tau \left(f + Bu_h - y_{ht} + \operatorname{div}(A\nabla y_h) \right. \\
 &\quad \left. + \int_0^t \operatorname{div}(\psi(t, \tau) \nabla y_h(\tau)) d\tau \right. \\
 &\quad \left. - \phi(y_h) \right)^2 dt,
 \end{aligned}$$

$$\begin{aligned}
 \eta_3^2 = &\int_0^T \sum_{\tau \in \mathcal{T}_h} h_l \int_{\partial\tau} \left[(A\nabla y_h) \cdot n \right. \\
 &\quad \left. + \int_0^t (\psi(t, \tau) \nabla y_h(\tau)) \cdot n d\tau \right]^2 dl dt, \\
 \eta_4^2 = &\|y_h(x, 0) - y_0(x)\|_{L^2(\Omega)}^2,
 \end{aligned} \tag{44}$$

where l is a face of an element τ , h_l is the size of face l , and $[(A\nabla y_h) \cdot n]$ is the A -normal derivative jump over the interior face l , defined by

$$[(A\nabla y_h) \cdot n]_l = (A\nabla y_h|_{\tau_l^1} - A\nabla y_h|_{\tau_l^2}) \cdot n, \tag{45}$$

where n is the unit normal vector on $l = \bar{\tau}_l^1 \cap \bar{\tau}_l^2$ outwards τ_l^1 . For convenience, one defines $[(A\nabla y_h) \cdot n]_l = 0$ when $l \subset \partial\Omega$.

Proof. Let e_I^y be the Clément-type interpolator of e^y defined in Lemma 1. It follows from (18) and (23) that we have

$$\begin{aligned}
 &((y_h - y(u_h))_t, w_h) + a(y_h - y(u_h), w_h) \\
 &\quad + \int_0^t \psi(t, \tau; (y_h - y(u_h))(\tau), w_h) d\tau \\
 &\quad + (\phi(y_h) - \phi(y(u_h)), w_h) = 0, \quad \forall w_h \in V_h.
 \end{aligned} \tag{46}$$

Let $e^y = y_h - y(u_h)$; by using (46), then we obtain

$$\begin{aligned}
 &((y_h - y(u_h))_t, e^y) + a(y_h - y(u_h), e^y) \\
 &\quad + \int_0^t \psi(t, \tau; (y_h - y(u_h))(\tau), e^y) d\tau \\
 &\quad + (\phi(y_h) - \phi(y(u_h)), e^y) \\
 &= ((y_h - y(u_h))_t, e^y - e_I^y) + a(y_h - y(u_h), e^y - e_I^y) \\
 &\quad + \int_0^t \psi(t, \tau; (y_h - y(u_h))(\tau), e^y - e_I^y) d\tau \\
 &\quad + (\phi(y_h) - \phi(y(u_h)), e^y - e_I^y) \\
 &= (y_{ht}, e^y - e_I^y) + a(y_h, e^y - e_I^y) \\
 &\quad + \int_0^t \psi(t, \tau; y_h(\tau), e^y - e_I^y) d\tau \\
 &\quad + (\phi(y_h), e^y - e_I^y) - (f + Bu_h, e^y - e_I^y) \\
 &= \sum_{\tau} \int_{\tau} \left(y_{ht} - \operatorname{div}(A\nabla y_h) \right. \\
 &\quad \left. - \int_0^t \operatorname{div}(\psi(t, \tau) \nabla y_h) d\tau \right. \\
 &\quad \left. + \phi(y_h) - f - Bu_h, e^y - e_I^y \right)
 \end{aligned}$$

$$\begin{aligned}
& + \sum_{\tau} \int_{\partial\tau} \left[(A\nabla y_h) \cdot n \right. \\
& \quad \left. + \int_0^t (\psi(t, \tau) \nabla y_h(\tau)) \cdot n d\tau \right] (e^y - e_I^y) \Big].
\end{aligned} \tag{47}$$

Then, we have

$$\begin{aligned}
& \frac{1}{2} \frac{d}{dt} \|y_h - y(u_h)\|_{0,\Omega}^2 + c \|y_h - y(u_h)\|_{1,\Omega}^2 \\
& \leq ((y_h - y(u_h))_t, e^y) + a (y_h - y(u_h), e^y) \\
& \quad + (\phi(y_h) - \phi(y(u_h)), e^y) \\
& \leq \sum_{\tau} \int_{\tau} \left(y_{ht} - \operatorname{div}(A\nabla y_h) - \int_0^t \operatorname{div}(\psi(t, \tau) \nabla y_h) d\tau \right. \\
& \quad \left. + \phi(y_h) - f - Bu_h, e^y - e_I^y \right) \\
& \quad + \sum_{\tau} \int_{\partial\tau} \left[(A\nabla y_h) \cdot n + \int_0^t (\psi(t, \tau) \nabla y_h(\tau)) \cdot n d\tau \right] \\
& \quad \times (e^y - e_I^y) \\
& \quad - \int_0^t \psi(t, \tau; (y_h - y(u_h))(\tau), e^y) d\tau.
\end{aligned} \tag{48}$$

By integrating time from 0 to t in the above inequality, combining (6) and the Schwartz inequality, we have

$$\begin{aligned}
& \frac{1}{2} \|y_h - y(u_h)\|_{0,\Omega}^2 + c \int_0^t \|y_h - y(u_h)\|_{1,\Omega}^2 d\tau \\
& \leq C \int_0^t \sum_{\tau} h_{\tau}^2 \int_{\tau} \left(y_{ht} - \operatorname{div}(A\nabla y_h) \right. \\
& \quad \left. - \int_0^t \operatorname{div}(\psi(t, \tau) \nabla y_h) d\tau \right. \\
& \quad \left. + \phi(y_h) - f - Bu_h \right)^2 d\tau \\
& \quad + \int_0^t \sum_{\tau} h_l \int_{\partial\tau} \left[(A\nabla y_h) \cdot n \right. \\
& \quad \left. + \int_0^t (\psi(t, \tau) \nabla y_h(\tau)) \cdot n d\tau \right]^2 d\tau \\
& \quad + \delta \int_0^t \|y_h - y(u_h)\|_{1,\Omega}^2 d\tau \\
& \quad + C \int_0^t \int_{\tau} \| (y_h - y(u_h))(s) \|_{1,\Omega}^2 ds d\tau \\
& \quad + \|y_h(x, 0) - y_0(x)\|_{L^2(\Omega)}^2.
\end{aligned} \tag{49}$$

Since δ is small enough, then from (49) and the Gronwall inequality, we have

$$\begin{aligned}
& \int_0^t \|y_h - y(u_h)\|_{1,\Omega}^2 d\tau \\
& \leq C \int_0^t \sum_{\tau} h_{\tau}^2 \int_{\tau} \left(y_{ht} - \operatorname{div}(A\nabla y_h) \right. \\
& \quad \left. - \int_0^t \operatorname{div}(\psi(t, \tau) \nabla y_h) d\tau \right. \\
& \quad \left. + \phi(y_h) - f - Bu_h \right)^2 d\tau \\
& \quad + C \int_0^t \sum_{\tau} h_l \int_{\partial\tau} \left[(A\nabla y_h) \cdot n + \int_0^t (\psi(t, \tau) \nabla y_h(\tau)) \right. \\
& \quad \left. \cdot n d\tau \right]^2 d\tau + \|y_h(x, 0) - y_0(x)\|_{L^2(\Omega)}^2.
\end{aligned} \tag{50}$$

So, by using the inequality (50) we obtain

$$\|y_h - y(u_h)\|_{L^2(J; H^1(\Omega))}^2 \leq C \sum_{i=2}^4 \eta_i^2. \tag{51}$$

This completes the proof. \square

Analogous to Theorem 3, we can prove the following estimates.

Theorem 4. Let $(y(u_h), p(u_h))$ and (y_h, p_h) be the solutions of (23)–(26) and (18)–(22), respectively. Then

$$\|p(u_h) - p_h\|_{L^2(J; H^1(\Omega))}^2 \leq C \sum_{i=2}^6 \eta_i^2, \tag{52}$$

where

$$\begin{aligned}
\eta_5^2 & = \int_0^T \sum_{\tau \in \mathcal{F}^h} h_{\tau}^2 \int_{\tau} \left(y_h - y_0 + p_{ht} + \operatorname{div}(A^* \nabla p_h) \right. \\
& \quad \left. + \int_t^T \operatorname{div}(\psi^*(\tau, t) \nabla p_h(\tau)) d\tau \right. \\
& \quad \left. - \phi'(y_h) p_h \right)^2 d\tau dt, \\
\eta_6^2 & = \int_0^T \sum_{\tau \in \mathcal{F}^h} h_l \int_{\partial\tau} \left[(A^* \nabla p_h) \cdot n \right. \\
& \quad \left. + \int_0^t ((\psi^*(t, \tau) \nabla p_h(\tau)) \cdot n) d\tau \right]^2 dl dt,
\end{aligned} \tag{53}$$

where $\eta_2 - \eta_4$ are defined in Theorem 3, l is a face of an element τ , and $[(A^* \nabla p_h) \cdot n]$ is the A -normal derivative jump over the interior face l , defined by

$$[(A^* \nabla p_h) \cdot n]_l = (A^* \nabla p_h|_{\tau_1^l} - A^* \nabla p_h|_{\tau_2^l}) \cdot n, \tag{54}$$

where n is the unit normal vector on $l = \bar{\tau}_l^1 \cap \bar{\tau}_l^2$ outwards τ_l^1 . For convenience, one defines $[(A \nabla p_h) \cdot n]_l = 0$ when $l \subset \partial \Omega$.

Proof. Let $e^p = p(u_h) - p_h$, and let $e_I^p = \hat{\pi}_h e^p$, where $\hat{\pi}_h$ is the Clément-type interpolator defined in Lemma 1. Then, from (20) and (25), we obtain

$$\begin{aligned} & - (q_h, (p_h - p(u_h))_t) + a(q_h, p_h - p(u_h)) \\ & + \int_t^T \psi(\tau, t; q_h(t), (p_h - p(u_h))(\tau)) d\tau \\ & + (\phi'(y_h) p_h - \phi'(y(u_h)) p(u_h), q_h) \\ & = (y_h - y(u_h), q_h), \quad \forall q_h \in V_h. \end{aligned} \quad (55)$$

Namely,

$$\begin{aligned} & - (q_h, (p_h - p(u_h))_t) + a(q_h, p_h - p(u_h)) \\ & + \int_t^T \psi(\tau, t; q_h(t), (p_h - p(u_h))(\tau)) d\tau \\ & + (\phi'(y_h) (p_h - p(u_h)), q_h) \\ & = (y_h - y(u_h), q_h) \\ & - ((\phi'(y_h) - \phi'(y(u_h))) p(u_h), q_h). \end{aligned} \quad (56)$$

By using (56), we obtain

$$\begin{aligned} & - (e^p, (p_h - p(u_h))_t) + a(e^p, p_h - p(u_h)) \\ & + \int_t^T \psi(\tau, t; e^p(t), (p_h - p(u_h))(\tau)) d\tau \\ & + (\phi'(y_h) (p_h - p(u_h)), e^p) \\ & = - (e^p - e_I^p, (p_h - p(u_h))_t) + a(e^p - e_I^p, p_h - p(u_h)) \\ & + \int_t^T \psi(\tau, t; (e^p - e_I^p)(t), (p_h - p(u_h))(\tau)) d\tau \\ & + (\phi'(y_h) (p_h - p(u_h)), e^p - e_I^p) \\ & - (e_I^p, (p_h - p(u_h))_t) + a(e_I^p, p_h - p(u_h)) \\ & + \int_t^T \psi(\tau, t; e_I^p(t), (p_h - p(u_h))(\tau)) d\tau \\ & + (\phi'(y_h) (p_h - p(u_h)), e_I^p) \\ & = - (e^p - e_I^p, (p_h - p(u_h))_t) + a(e^p - e_I^p, p_h - p(u_h)) \\ & + \int_t^T \psi(\tau, t; (e^p - e_I^p)(t), (p_h - p(u_h))(\tau)) d\tau \\ & + (\phi'(y_h) (p_h - p(u_h)), e^p - e_I^p) + (y_h - y(u_h), e_I^p) \\ & - ((\phi'(y_h) - \phi'(y(u_h))) p(u_h), e_I^p) \end{aligned}$$

$$\begin{aligned} & = - (e^p - e_I^p, p_{ht}) + a(e^p - e_I^p, p_h) \\ & + \int_t^T \psi(\tau, t; (e^p - e_I^p)(t), p_h)(\tau) d\tau \\ & + (\phi'(y_h) (p_h), e^p - e_I^p) \\ & + (e^p - e_I^p, p_t(u_h)) - a(e^p - e_I^p, p(u_h)) \\ & - \int_t^T \psi(\tau, t; (e^p - e_I^p)(t), p(u_h)(\tau)) d\tau \\ & - (\phi'(y_h) (p(u_h)), e^p - e_I^p) + (y_h - y(u_h), e_I^p) \\ & - ((\phi'(y_h) - \phi'(y(u_h))) p(u_h), e_I^p) \\ & = \sum_{\tau} \int_{\tau} \left(-y_h + y_0 - p_{ht} - \operatorname{div}(A^* \nabla p_h) \right. \\ & \quad \left. - \int_t^T \operatorname{div}(\psi^*(\tau, t) \nabla p_h(\tau)) d\tau + \phi'(y_h) p_h \right) \\ & \quad \times (e^p - e_I^p) \\ & + \sum_{\tau} \int_{\partial \tau} \left((A^* \nabla p_h) \cdot n + \int_0^t ((\psi^*(t, \tau) \nabla p_h(\tau)) \cdot n) d\tau \right) \\ & \quad \times (e^p - e_I^p) + (y_h - y(u_h), e_I^p) \\ & - ((\phi'(y_h) - \phi'(y(u_h))) p(u_h), e^p). \end{aligned} \quad (57)$$

Then, we have

$$\begin{aligned} & - \frac{1}{2} \frac{d}{dt} \|p_h - p(u_h)\|_{0, \Omega}^2 + c \|p_h - p(u_h)\|_{1, \Omega}^2 \\ & \leq - (e^p, (p_h - p(u_h))_t) + a(e^p, p_h - p(u_h)) \\ & \quad + (\phi'(y_h) (p_h - p(u_h)), e^p) \\ & \leq \sum_{\tau} \int_{\tau} \left(-y_h + y_0 - p_{ht} - \operatorname{div}(A^* \nabla p_h) \right. \\ & \quad \left. - \int_t^T \operatorname{div}(\psi^*(\tau, t) \nabla p_h(\tau)) d\tau \right. \\ & \quad \left. + \phi'(y_h) p_h \right) (e^p - e_I^p) \\ & + \sum_{\tau} \int_{\partial \tau} \left((A^* \nabla p_h) \cdot n \right. \\ & \quad \left. + \int_t^T ((\psi^*(t, \tau) \nabla p_h(\tau)) \cdot n) d\tau \right) \\ & \quad \times (e^p - e_I^p) + (y_h - y(u_h), e_I^p) \\ & - ((\phi'(y_h) - \phi'(y(u_h))) p(u_h), e^p) \\ & + \int_t^T \psi(\tau, t; e^p(t), (p_h - p(u_h))(\tau)) d\tau. \end{aligned} \quad (58)$$

By integrating time from t to T in the above inequality, combining (6) and the Schwartz inequality, we have

$$\begin{aligned}
& \frac{1}{2} \|p_h - p(u_h)\|_{0,\Omega}^2 + c \int_t^T \|p_h - p(u_h)\|_{1,\Omega}^2 d\tau \\
& \leq C \int_t^T \sum_{\tau} h_{\tau}^2 \int_{\tau} \left(y_h - y_0 + p_{ht} + \operatorname{div}(A^* \nabla p_h) \right. \\
& \quad \left. + \int_t^T \operatorname{div}(\psi^*(\tau, t) \nabla p_h(\tau)) d\tau \right. \\
& \quad \left. - \phi'(y_h) p_h \right)^2 d\tau \\
& \quad + \int_t^T \sum_{\tau} h_{\tau} \int_{\partial\tau} \left[(A^* \nabla p_h) \cdot n \right. \\
& \quad \left. + \int_t^T ((\psi^*(t, \tau) \nabla p_h(\tau)) \cdot n) d\tau \right]^2 d\tau \\
& \quad + \delta \int_t^T \|p_h - p(u_h)\|_{1,\Omega}^2 d\tau \\
& \quad + C \int_t^T \int_{\tau} \|(p_h - p(u_h))(s)\|_{1,\Omega}^2 ds d\tau \\
& \quad + C \int_t^T \int_{\tau} \|y_h - y(u_h)\|_{0,\Omega}^2 d\tau.
\end{aligned} \tag{59}$$

Since δ is small enough, then from (59) and the Gronwall inequality, we have

$$\begin{aligned}
& \int_t^T \|p_h - p(u_h)\|_{1,\Omega}^2 d\tau \\
& \leq C \int_t^T \sum_{\tau} h_{\tau}^2 \int_{\tau} \left(y_h - y_0 + p_{ht} + \operatorname{div}(A^* \nabla p_h) \right. \\
& \quad \left. + \int_t^T \operatorname{div}(\psi^*(\tau, t) \nabla p_h(\tau)) d\tau \right. \\
& \quad \left. - \phi'(y_h) p_h \right)^2 d\tau \\
& \quad + \int_t^T \sum_{\tau} h_{\tau} \int_{\partial\tau} \left[(A^* \nabla p_h) \cdot n \right. \\
& \quad \left. + \int_t^T ((\psi^*(t, \tau) \nabla p_h(\tau)) \cdot n) d\tau \right]^2 d\tau \\
& \quad + \|y(u_h) - y_h\|_{L^2(J;L^2(\Omega))}^2
\end{aligned}$$

$$\begin{aligned}
& \leq C \int_t^T \sum_{\tau} h_{\tau}^2 \int_{\tau} \left(y_h - y_0 + p_{ht} + \operatorname{div}(A^* \nabla p_h) \right. \\
& \quad \left. + \int_t^T \operatorname{div}(\psi^*(\tau, t) \nabla p_h(\tau)) d\tau \right. \\
& \quad \left. - \phi'(y_h) p_h \right)^2 d\tau \\
& \quad + \int_t^T \sum_{\tau} h_{\tau} \int_{\partial\tau} \left[(A^* \nabla p_h) \cdot n \right. \\
& \quad \left. + \int_t^T ((\psi^*(t, \tau) \nabla p_h(\tau)) \cdot n) d\tau \right]^2 d\tau \\
& \quad + \|y(u_h) - y_h\|_{L^2(J;H^1(\Omega))}^2.
\end{aligned} \tag{60}$$

Finally, combine inequality (60) and Theorem 3 to obtain

$$\|p(u_h) - p_h\|_{L^2(J;H^1(\Omega))}^2 \leq C \sum_{i=2}^6 \eta_i^2. \tag{61}$$

This completes the proof. \square

Hence, we combine Theorems 2–4 to conclude.

Theorem 5. Let (y, p, u) and (y_h, p_h, u_h) be the solutions of (10)–(14) and (18)–(22), respectively. Then

$$\begin{aligned}
& \|u - u_h\|_{L^2(J;L^2(\Omega))}^2 + \|y - y_h\|_{L^2(J;H^1(\Omega))}^2 \\
& \quad + \|p - p_h\|_{L^2(J;H^1(\Omega))}^2 \leq C \sum_{i=1}^6 \eta_i^2,
\end{aligned} \tag{62}$$

where η_1 – η_6 are defined in Theorems 2–4, respectively.

Proof. From (10)–(14) and (23)–(26), we obtain the error equations

$$\begin{aligned}
& (y_t - y_t(u_h), w) + a(y - y(u_h), w) \\
& \quad + \int_0^t \psi(t, \tau; (y - y(u_h))(\tau), w_h) d\tau \\
& \quad + (\phi(y) - \phi(y(u_h)), w) = (B(u - u_h), w), \\
& \quad - (p_t - p_t(u_h), q) + a(q, p - p(u_h)) \\
& \quad + \int_t^T \psi(\tau, t; q_h(t), (p - p(u_h))(\tau)) d\tau \\
& \quad + (\phi'(y) p - \phi'(y(u_h)) p(u_h), q) = (y - y(u_h), q)
\end{aligned} \tag{63}$$

for all $w \in V$ and $q \in V$. Thus, it follows from (63) that

$$\begin{aligned}
& (y_t - y_t(u_h), w) + a(y - y(u_h), w) \\
& \quad + \int_0^t \psi(t, \tau; (y - y(u_h))(\tau), w_h) d\tau \\
& \quad + (\phi(y) - \phi(y(u_h)), w) = (B(u - u_h), w),
\end{aligned}$$

$$\begin{aligned}
 & - (p_t - p_t(u_h), q) + a(q, p - p(u_h)) \\
 & + \int_t^T \psi(\tau, t; q_h(t), (p - p(u_h))(\tau)) d\tau \\
 & + (\phi'(y(u_h))(p - p(u_h)), q) \\
 & = (y - y(u_h), q) + (\tilde{\phi}''(y(u_h))(y(u_h) - y), p, q).
 \end{aligned} \tag{64}$$

By using the stability results in [17, 19], then we can prove that

$$\begin{aligned}
 \|y - y(u_h)\|_{L^2(J; H^1(\Omega))}^2 & \leq C \|u - u_h\|_{L^2(J; L^2(\Omega))}^2, \\
 \|p - p(u_h)\|_{L^2(J; H^1(\Omega))}^2 & \leq \|y - y(u_h)\|_{L^2(J; H^1(\Omega))}^2 \\
 & \leq C \|u - u_h\|_{L^2(J; L^2(\Omega))}^2.
 \end{aligned} \tag{65}$$

Finally, combining Theorems 2–4 and (65) leads to (62). \square

4. An Adaptive Algorithm

In this section, we introduce an adaptive algorithm to guide the mesh refinement process. A posteriori error estimates which have been derived in Section 3 are used as an error indicator to guide the mesh refinement in adaptive finite element method.

Now, we discuss the adaptive mesh refinement strategy. The general idea is to refine the mesh such that the error indicator like η is equally distributed over the computational mesh. Assume that an a posteriori error estimator η has the form of $\eta^2 = \sum_{\tau_i} \eta_{\tau_i}^2$, where τ_i is the finite elements. At each iteration, an average quantity of all $\eta_{\tau_i}^2$ is calculated, and each $\eta_{\tau_i}^2$ is then compared with this quantity. The element τ_i is to be refined if $\eta_{\tau_i}^2$ is larger than this quantity. As $\eta_{\tau_i}^2$ represents the total approximation error over τ_i , this strategy makes sure that higher density of nodes is distributed over the area where the error is higher.

Based on this principle, we define an adaptive algorithm of the semilinear parabolic integrodifferential optimal control problems (1)-(2) as follows: starting from initial triangulations \mathcal{T}_{h_0} of Ω , we construct a sequence of refined triangulation \mathcal{T}_{h_j} as follows. Given \mathcal{T}_{h_j} , we compute the solutions (y_h, p_h, u_h) of the system (18)–(22) and their error estimator as follows:

$$\begin{aligned}
 \eta_{\tau}^2 & = \int_0^T \sum_{\tau \in \mathcal{T}_h} h_{\tau}^{1+s} \|\alpha u_h + B^* p_h\|_{H^s(\tau)}^{1+s} dt \\
 & + \int_0^T \sum_{\tau \in \mathcal{T}_h} h_{\tau}^2 \int_{\tau} \left(f + Bu_h - y_{ht} + \operatorname{div}(A \nabla y_h) \right. \\
 & \quad \left. + \int_0^t \operatorname{div}(\psi(t, \tau) \nabla y_h(\tau)) d\tau \right. \\
 & \quad \left. - \phi(y_h) \right)^2 d\tau dt
 \end{aligned}$$

$$\begin{aligned}
 & + \int_0^T \sum_{\tau \in \mathcal{T}_h} h_{\tau} \int_{\partial \tau} \left[(A \nabla y_h) \cdot n \right. \\
 & \quad \left. + \int_0^t ((\psi(t, \tau) \nabla y_h(\tau)) \cdot n) d\tau \right]^2 dl dt \\
 & + \|y_h(x, 0) - y_0(x)\|_{L^2(\Omega)}^2 \\
 & + \int_0^T \sum_{\tau \in \mathcal{T}_h} h_{\tau}^2 \int_{\tau} \left(y_h - y_0 + p_{ht} + \operatorname{div}(A^* \nabla p_h) \right. \\
 & \quad \left. + \int_t^T \operatorname{div}(\psi^*(\tau, t) \nabla p_h(\tau)) d\tau \right. \\
 & \quad \left. - \phi'(y_h) p_h \right) d\tau dt \\
 & + \int_0^T \sum_{\tau \in \mathcal{T}_h} h_{\tau} \int_{\partial \tau} \left[(A^* \nabla p_h) \cdot n \right. \\
 & \quad \left. + \int_0^t ((\psi^*(t, \tau) \nabla p_h(\tau)) \cdot n) d\tau \right]^2 dl dt, \\
 E_j & = \sum_{\tau \in \mathcal{T}_h} \eta_{\tau}^2.
 \end{aligned} \tag{66}$$

Then, we adopt the following mesh refinement strategy: all the triangles $\tau \in \mathcal{T}_{h_j}$ satisfying $\eta_{\tau}^2 \geq \rho E_j/n$ are divided into four new triangles in $\mathcal{T}_{h_{j+1}}$ by joining the midpoints of the edges, where n is the number of the elements of \mathcal{T}_{h_j} and ρ is a given constant. In order to maintain the new triangulation $\mathcal{T}_{h_{j+1}}$ to be regular and conformal, some additional triangles need to be divided into two or four new triangles depending on whether they have one or more neighbors which have been refined. Then, we obtain the new mesh $\mathcal{T}_{h_{j+1}}$. The above procedure will continue until $E_j \leq \text{tol}$, where tol is a given tolerance error.

5. Numerical Example

In this section, we will give a numerical example to illustrate our theoretical results. Our numerical example is the following semilinear parabolic integrodifferential optimal control problem:

$$\begin{aligned}
 & \min_{u(t) \in K} \left\{ \int_0^1 \left(\frac{1}{2} \|y - y_0\|^2 + \frac{1}{2} \|u - u_0\|^2 \right) dt \right\} \\
 & y_t - \operatorname{div}(\nabla y(x, t)) - \int_0^t \operatorname{div}(\psi(t, \tau) \nabla y(x, \tau)) d\tau \\
 & + \phi(y) = f + u, \quad x \in \Omega, t \in J,
 \end{aligned}$$

$$\begin{aligned}
y(x, t) &= 0, \quad x \in \partial\Omega, \quad t \in J, \\
y(x, 0) &= 0, \quad x \in \Omega, \\
-p_t - \operatorname{div}(\nabla p(x, t)) - \int_t^1 \operatorname{div}(\psi^*(\tau, t) \nabla p(x, \tau)) d\tau \\
&+ \phi'(y) p = y - y_0, \quad x \in \Omega, \quad t \in J, \\
p(x, t) &= 0, \quad x \in \partial\Omega, \quad t \in J, \\
p(x, 1) &= 0, \quad x \in \Omega.
\end{aligned} \tag{67}$$

In this example, we choose the domain $\Omega = [0, 1] \times [0, 1]$. Let Ω be partitioned into \mathcal{T}_h as described Section 2. For the constrained optimization problem:

$$\min_{u \in K \subset U} \int_0^1 S(u) dt, \tag{68}$$

where $S(u) = (1/2)\|y - y_0\|^2 + (1/2)\|u - u_0\|^2$ is a convex functional on U and $K = \{u \in U : u \geq 0 \text{ a.e. in } \Omega \times J\}$; the iterative scheme reads ($n = 0, 1, 2, \dots$)

$$\begin{aligned}
b(u_{n+1/2}, v) &= b(u_n, v) - \rho_n (S'(u_n), v), \quad \forall v \in U, \\
u_{n+1} &= P_K^b(u_{n+1/2}),
\end{aligned} \tag{69}$$

where $b(\cdot, \cdot)$ is a symmetric and positive definite bilinear form such that there exist constants c_0 and c_1 satisfying

$$\begin{aligned}
|b(u, v)| &\leq c_1 \|u\|_U \|v\|_U, \quad \forall u, v \in U, \\
b(u, u) &\geq c_0 \|u\|_U^2,
\end{aligned} \tag{70}$$

and the projection operator $P_K^b U \rightarrow K$ is defined: for given $w \in U$ find $P_K^b w \in K$ such that

$$b(P_K^b w - w, P_K^b w - w) = \min_{u \in K} b(u - w, u - w). \tag{71}$$

The bilinear form $b(\cdot, \cdot)$ provides suitable preconditioning for the projection algorithm. An application of (69) to the discretized semilinear parabolic integrodifferential optimal control problem yields the following algorithm:

$$\begin{aligned}
b(u_{n+1/2}, v_h) &= b(u_n, v_h) - \rho_n (u_n + p_n, v_h), \quad \forall v_h \in K_h, \\
\int_0^1 \left((y_t, w) + a(y, w) + \int_0^t \psi(\tau, t; y(\tau), w) d\tau \right. \\
&\left. + (\phi(y), w) \right) dt = \int_0^1 (f + u, w) dt, \quad \forall w \in V, \\
\int_0^1 \left(-(p_t, q) + a(q, p) + \int_t^1 \psi(\tau, t; q, p(\tau)) d\tau \right. \\
&\left. + (\phi'(y) p, q) \right) dt = \int_0^1 (y - y_0, q) dt, \quad \forall q \in V, \\
u_{n+1} &= P_K^b(u_{n+1/2}), \quad u_{n+1/2}, u_n \in K_h.
\end{aligned} \tag{72}$$

The main computational effort is to solve the state and costate equations and to compute the projection $P_K^b u_{n+1/2}$. In this paper, we use a fast algebraic multigrid solver to solve the state and costate equations. Then, it is clear that the key to saving computing time is how to compute $P_K^b u_{n+1/2}$ efficiently. For the piecewise constant elements, $K_h = \{u_h : u_h \geq 0\}$ and $b(u, v) = (u, v)_U$; then

$$P_K^b u_{n+1/2}|_\tau = \max(0, \operatorname{avg}(u_{n+1/2})|_\tau), \tag{73}$$

where $\operatorname{avg}(u_{n+1/2})|_\tau$ is the average of $u_{n+1/2}$ over τ .

In solving our discretized optimal control problem, we use the preconditioned projection gradient method with $b(u, v) = (u, v)_U$ and a fixed step size $\rho = 0.9$. We now briefly describe the solution algorithm to be used for solving the numerical example in this section as follows.

- (1) Solve the discretized optimization problem with the projection gradient method on the current meshes and calculate the error estimators η_i .
- (2) Adjust the meshes using the estimators and update the solution on new meshes, as described.

Now, we give a numerical example to illustrate our theoretical results.

Example 1. Let $\psi(t, \tau) = 1$, $\phi(y) = y^5$. We choose the state function by

$$y(x_1, x_2) = 2 \sin \pi x_1 \sin \pi x_2 \sin \pi t. \tag{74}$$

The function f is given by $f(x) = y_t - \operatorname{div}(\nabla y(x, t)) - \int_0^t \operatorname{div}(\nabla y(x, \tau)) d\tau + y^5 - u$. The costate function can be chosen as

$$p(x_1, x_2) = \sin \pi x_1 \sin \pi x_2 \sin \pi t. \tag{75}$$

The function y_0 is given by $y_0(x) = y + p_t + \operatorname{div}(\nabla p(x, t)) + \int_t^1 \operatorname{div}(\nabla p(x, \tau)) d\tau - 5y^4 p$. We assume that

$$\lambda = \begin{cases} 0.8, & x_1 + x_2 > 1.0, \\ 0.3, & x_1 + x_2 \leq 1.0, \end{cases} \tag{76}$$

$$u_0(x_1, x_2) = 1 - \sin \frac{\pi x_1}{2} - \sin \frac{\pi x_2}{2} + \lambda.$$

Thus, the control function is given by

$$u(x_1, x_2) = \max(u_0 - p, 0). \tag{77}$$

In this example, the control function u has a strong discontinuity introduced by u_0 . The control function u is discretized by piecewise constant functions, whereas the state y and the costate p were approximated by piecewise linear functions. In Table 1, numerical results of u , y , and p on uniform and adaptive meshes are presented. It can be found that the adaptive meshes generated using our error indicators can save substantial computational work, in comparison with the uniform meshes. On the other hand, for the discontinuous control variable u , the accuracy has become better from the uniform meshes to the adaptive meshes in Table 1.

TABLE I: Numerical results on uniform and adaptive meshes.

	On uniform mesh			On adaptive mesh

6. Conclusion and Future Works

In this paper, we discuss the semi-discrete finite element methods of the semilinear parabolic integrodifferential optimal control problems (1)-(2). We have established a posteriori error estimates for each the state, the costate, and the control approximation. The posteriori error estimates for those problems by finite element methods seem to be new.

In our future work, we will use the mixed finite element method to deal with nonlinear parabolic integrodifferential optimal control problems. Furthermore, we will consider a posteriori error estimates and superconvergence of mixed finite element solution for nonlinear parabolic integrodifferential optimal control problems.

Acknowledgments

The author expresses his thanks to the referees for their helpful suggestions, which led to improvements of the presentation.
