# Slowdown estimates for one-dimensional random walks in random environment with holding times

Amir Dembo\*      Ryoki Fukushima†      Naoki Kubota‡

## Abstract

We consider a one dimensional random walk in random environment that is uniformly biased to one direction. In addition to the transition probability, the jump rate of the random walk is assumed to be spatially inhomogeneous and random. We study the probability that the random walk travels slower than its typical speed and determine its decay rate asymptotic.

**Keywords:** random walk; random environment; large deviation; slowdown.

**AMS MSC 2010:** 60K37; 60F10; 60J15.

## 1 Introduction

### 1.1 Setting and preliminaries

Let  $(\omega = \{\omega(x)\}_{x \in \mathbb{Z}}, \mathbf{P})$  be independent and identically distributed random variables taking values in  $(0, 1)$ . For a given  $\omega$ , the random walk in random environment  $\{X_n\}_{n=0}^\infty$  is the Markov chain with transition probability

$$\begin{aligned}\omega(x) &= P^\omega(X_{n+1} = x + 1 | X_n = x) \\ &= 1 - P^\omega(X_{n+1} = x - 1 | X_n = x).\end{aligned}\tag{1.1}$$

It is said to be uniformly biased (to the right) if  $\mathbf{P}\text{-ess\,inf} \omega(0) > 1/2$ . In this case, the law of large numbers is known to hold with a positive speed (see [19]):

$$\lim_{n \rightarrow \infty} \frac{1}{n} X_n = v_{\mathbf{P}} > 0.\tag{1.2}$$

In this paper, we consider a variant of this process whose jump rate is spatially inhomogeneous and random. Specifically, as in [5], let  $(\mu = \{\mu(x)\}_{x \in \mathbb{Z}}, \mathbb{P})$  be independent and identically distributed strictly positive random variables of mean one. For a given  $\mu$ , we consider a continuous time random walk  $(X = \{X_t\}_{t \geq 0}, \{P_z^{\omega, \mu}\}_{z \in \mathbb{Z}})$  on  $\mathbb{Z}$  whose jump rates from  $x$  to  $x + 1$  and  $x - 1$  are given by  $\omega(x)/\mu(x)$  and  $(1 - \omega(x))/\mu(x)$ , respectively.

This type of random walk (usually with  $\omega \equiv 1/2$ ) is sometimes called a random hopping time dynamics. If in addition the mean of  $\mu(0)$  is infinite, it is also called Bouchaud's trap model. Since we assumed finite mean, there is no trapping effect and it is easy to check that the law of large numbers holds:

$$P_0^{\omega, \mu} \left( \lim_{t \rightarrow \infty} \frac{1}{t} X_t = v_{\mathbf{P}} \right) = 1 \quad \mathbf{P} \otimes \mathbf{P}\text{-almost surely.} \tag{1.3}$$

The large deviation principle of rate  $t$  also holds for the law of  $\{t^{-1}X_t\}_{t>0}$  as a special case of the results of [5]. However, when  $\mu$  is unbounded, it is easily seen that the slowdown probability

$$P_0^{\omega, \mu} (X_t < vt) \text{ for } v \in (0, v_{\mathbf{P}}) \tag{1.4}$$

exhibits sub-exponential decay. The aim of this work is to establish the precise sub-exponential rate of the slowdown probability decay and relate it to the tail of the law of  $\mu(x)$ . While our methods apply for quite general distributions of  $\mu$ , we consider three representative classes (Pareto, Intermediate and Weibull) to make the statements concise. To be precise, suppose

$$\mathbf{P}(\mu(0) > r) = \exp\{-g(r)\} \tag{1.5}$$

and  $g$  has either of the following forms:

- (P)  $e^{g(r)}$  is regularly varying at  $\infty$  with index  $\alpha > 1$ ;
- (I)  $g$  is slowly varying at  $\infty$  satisfying  $\lim_{r \rightarrow \infty} g(r)/\log r = \infty$ ;
- (W)  $g$  is regularly varying with index  $\alpha > 0$  at  $\infty$ .

Furthermore, when  $g$  satisfies (W) with  $\alpha = 1$ , we assume in addition that the so-called Cramér condition holds:

- (C) there exists  $C > 0$  such that  $\mathbb{E}[e^{C\mu(0)}] < \infty$ .

In the quenched slowdown estimate, the extreme value of  $\mu$  plays an important role.

Let us recall two results from extreme value theory. Let  $g^{-1}$  denote the left-continuous inverse of  $g$ . The first result gives us a condition under which the running maxima of  $\{\mu(x)\}_{x \in \mathbb{Z}}$  can be approximated by a deterministic sequence up to multiplicative constant.

**Lemma 1.1.** *Suppose that*

$$l = \sup\{\lambda \geq 1 : \mathbb{E}[\exp\{g(\lambda\mu(0))\}] < \infty\} < \infty. \tag{1.6}$$

Then

$$l^{-1} \leq \liminf_{t \rightarrow \infty} \frac{\max_{0 \leq x \leq t} \{\mu(x)\}}{g^{-1}(\log t)} \leq \limsup_{t \rightarrow \infty} \frac{\max_{0 \leq x \leq t} \{\mu(x)\}}{g^{-1}(\log t)} \leq l. \tag{1.7}$$

This can be found in [16, Corollary 1]. Any distribution in the class (W) satisfies (1.6) with  $l = 1$ . For the class (I), it is satisfied for  $g(r) = (\log r)^\beta 1_{\{r \geq 1\}}$  ( $\beta > 1$ ) with  $l = 1$  and  $g(r) = \log r \log \log r 1_{\{r \geq e\}}$  with  $l = e$ , but not for  $g(r) = \log r \log \log \log r 1_{\{r \geq e^e\}}$ . No distribution in (P) satisfies (1.6): indeed, the regular variation assumption implies  $\lim_{x \rightarrow \infty} g(x) - g(\delta x) = -\alpha \log \delta$ , and then we know from [22, Lemma 2.2-(i)] that (1.6) fails to hold for any  $l \geq 1$ .

In order to cover the cases where (1.6) fails to hold, we state another lemma which readily follows from [7, Theorems 3.5.1 and 3.5.2]:

**Lemma 1.2.** *For any  $\epsilon > 0$ ,  $\mathbf{P}$ -a.s., for all sufficiently large  $t$ ,*

$$g^{-1}((1 - \epsilon) \log t) \leq \max_{0 \leq x \leq t} \{\mu(x)\} \leq g^{-1}((1 + \epsilon) \log t). \tag{1.8}$$

This lemma aims at giving an easily computable asymptotic bound and is not sharp. Once an explicit form of the distribution is given, one can often obtain a finer asymptotics from [7, Theorems 3.5.1 and 3.5.2]. For example, if  $g(r) = \alpha \log r 1_{\{r \geq e\}}$ , then it is shown in [23, Lemma 3.3] that

$$\mathbb{P} \left( v_c(t) \leq \max_{0 \leq x \leq t} \{\mu(x)\} \leq u_\rho(t) \text{ eventually} \right) = \begin{cases} 1, & \text{if } \rho > 0 \text{ and } c \in (0, 1), \\ 0, & \text{if } \rho \leq 0 \text{ or } c \geq 1, \end{cases} \quad (1.9)$$

where

$$u_\rho(t) = (t \log t \log \log t)^{1/\alpha} (\log \log \log t)^{1/\alpha + \rho}, \quad (1.10)$$

$$v_c(t) = c(t / \log \log t)^{1/\alpha}. \quad (1.11)$$

### 1.2 Results

To simplify the presentation, we introduce the following notation:

**Definition 1.3.** For two functions  $f, g: (0, \infty) \rightarrow (0, \infty)$ , we write  $f(t) \asymp_{\log} g(t)$  when there exists a  $c \in (0, \infty)$  such that for all sufficiently large  $t$ ,

$$c^{-1} \log g(t) \leq \log f(t) \leq c \log g(t). \quad (1.12)$$

When only the left inequality holds, we write  $f(t) \lesssim_{\log} g(t)$ .

Our first result is the following quenched slowdown estimate.

**Theorem 1.4.** Let  $\mathbf{P}$  be a uniformly biased environment:  $\mathbf{P}\text{-essinf } \omega(0) > 1/2$ . For any  $v \in (0, v_{\mathbf{P}})$ ,  $\mathbf{P} \otimes \mathbb{P}$ -almost surely,

$$\exp \left\{ -\frac{t}{g^{-1}((1-\epsilon)\log t)} \right\} \lesssim_{\log} P_0^{\omega, \mu} (X_t < vt) \lesssim_{\log} \exp \left\{ -\frac{t}{g^{-1}((1+\epsilon)\log t)} \right\}. \quad (1.13)$$

Moreover, if  $\mu$  satisfies the assumption of Lemma 1.1, then

$$P_0^{\omega, \mu} (X_t < vt) \asymp_{\log} \exp \left\{ -\frac{t}{g^{-1}(\log t)} \right\}. \quad (1.14)$$

Our second result is the corresponding annealed slowdown estimate. To this end, for each  $t$ , let  $h(t)$  be the largest  $h > 0$  satisfying

$$\frac{t}{h} \geq g(h) - \log t. \quad (1.15)$$

Such  $h$  exists for all large  $t$ . Indeed, when  $t$  is large, the inequality (1.15) holds for  $h = \log t$  and fails for  $h = t$ , whereas per fixed  $t > 0$  the left hand side of (1.15) is decreasing in  $h$  and its right hand side eventually increasing in  $h$ .

**Remark 1.5.** In general, both  $h(t)$  and  $g(h(t))$  grow sub-linearly in  $t$ . Furthermore, it is straightforward to check that

$$h(t) \sim \begin{cases} \frac{t}{(\alpha-1)\log t} & \text{for (P),} \\ t^{\frac{1}{\alpha+1}} \ell(t) & \text{for (W),} \end{cases} \quad (1.16)$$

where the function  $\ell(t)$  is slowly varying at  $\infty$ . There is no such simple formula in the case (I) but for a representative example  $g(r) = (\log r)^\beta$  ( $\beta > 1$ ), we have

$$h(t) \sim \frac{t}{(\log t)^\beta}. \quad (1.17)$$

**Theorem 1.6.** *Let  $\mathbf{P}$  be a uniformly biased environment:  $\mathbf{P}\text{-essinf}\omega(0) > 1/2$ . Suppose  $v \in (0, v_{\mathbf{P}})$ . Then for  $h(\cdot)$  of (1.15),*

$$\mathbf{P} \otimes \mathbb{P} [P_0^{\omega, \mu} (X_t < vt)] \asymp_{\log} \exp \left\{ -\frac{t}{h(t)} \right\}, \quad (1.18)$$

where  $\mathbf{P} \otimes \mathbb{P}[\cdot]$  denotes the expectation with respect to  $\mathbf{P} \otimes \mathbb{P}$ .

### 1.3 Related works

Sub-exponential tail estimates are established in [6] for the annealed slowdown probability of the random walk in random environment  $(X_n)_{n \geq 0}$  governed by (1.1). When the environment assumes both positive and negative drift, that is,  $\mathbf{P}\text{-essinf}\omega(0) < 1/2 < \mathbf{P}\text{-esssup}\omega(0)$ , the annealed slowdown probability exhibits a polynomial decay. In the case of positive and zero drift, that is,  $\mathbf{P}\text{-essinf}\omega(0) = 1/2$ , under an additional assumption that  $\mathbf{P}(\omega(0) = 1/2) > 0$ , the slowdown probability is shown to decay stretched exponentially with exponent  $1/3$ . The rate of decay of the corresponding quenched slowdown probability is determined in [8], based on the annealed result and the block argument. In the case of positive and zero drift, both annealed and quenched results are refined to the precision of the usual large deviation principle in [15] and [14], respectively. On the other hand, in the case of positive and negative drift, it has recently been shown in [1] that the leading order of the quenched slowdown probability oscillates and hence does not satisfy a large deviation principle. For more details, we refer the reader to a survey article [9] as well as the introduction of [1].

We focus here on the uniformly biased situation with (inhomogeneous) holding times. Indeed, for uniformly biased environments, the result of [10] shows that without holding times the slowdown probability decays exponentially. Thus, the sub-exponential decay of the slowdown probability is caused in this setting solely by the inhomogeneity of holding times. Note that in case of positive and negative drift, since the annealed slowdown probability decays polynomially without holding times, the holding time can cause a visible effect only if  $\mu$  has a power law tail. Similarly, in the case of positive and zero drift, the most natural choice of  $\mu$  would be the Weibull distribution. We leave the latter two cases for future research.

Finally, [20, 21, 2] provide estimates for the decay rate of the slowdown probability for random walk in random environment in higher dimensions. While it is interesting to see how the holding times affect such slowdown probabilities, our method relies on a certain renewal structure which is limited to the one dimensional setting.

### 1.4 Outline

Section 2 provide the relatively easy proofs of our lower bounds, where in both quenched and annealed settings, we simply let the random walk stay until time  $t$  at the site of the highest  $\mu$ -value within  $[0, vt - 1]$ . In the quenched case, the highest  $\mu$ -value behaves as in Lemmas 1.1 and 1.2, while in the annealed setting, we can make it larger at a suitable cost in  $\log \mathbb{P}$ -probability, so we optimize the sum of the corresponding cost and gain.

The derivation of the upper bounds is more involved. Since a sub-exponential slowdown decay for a uniformly biased random walk can only be caused by the inhomogeneity of the holding times  $\mu$ , we introduce in Section 3 a suitable time change and thereby reduce such upper bounds on the slowdown decay to a tail bound for certain additive functionals. Section 4 provides our main technical contribution, showing that conditioning on some good events with respect to  $\omega$  and  $\mu$  yields the stated upper bounds. Finally, in Section 5, we show that

- (i) in the quenched setting, the good event has probability one;
- (ii) in the annealed setting, the good event has probability comparable to the upper bound in Theorem 1.6.

## 2 Lower bounds

*Proof of the lower bound in Theorem 1.4.* Let us define a regularly varying function

$$M(t) = \begin{cases} g^{-1}((1 - \epsilon) \log t), & \text{or} \\ g^{-1}(\log t), & \text{when (1.6) holds.} \end{cases} \quad (2.1)$$

Then due to Lemmas 1.1 and 1.2, the following holds  $\mathbb{P}$ -almost surely: for all sufficiently large  $t$ , there exist a point  $x \in [0, vt - 1]$  and  $c_v > 0$  (which is independent of  $x$ ) such that  $\mu(x) \geq c_v M(t)$ . It follows that

$$P_0^{\omega, \mu}(X_t < vt) \geq P_0^{\omega, \mu}(\tau_1(x) \geq t) \geq \exp\left\{-\frac{t}{c_v M(t)}\right\}, \quad (2.2)$$

where  $\tau_1(x)$  is the first holding time at  $x$ , which is distributed as  $\text{Exp}(1/\mu(x))$ . □

*Proof of the lower bound in Theorem 1.6.* As in the quenched case, if there is a point  $x \in [0, vt - 1]$  such that  $\mu(x) \geq h(t)$ , then we can slow the random walk by using the first holding time at  $x$ . Therefore, by the definition of  $h(t)$ , we have

$$\begin{aligned} \mathbf{P} \otimes \mathbb{P} [P_0^{\omega, \mu}(X_t < vt)] &\geq \exp\left\{-\frac{t}{h(t)}\right\} \mathbb{P}\left(\max_{x \in [0, vt-1]} \mu(x) \geq h(t)\right) \\ &\asymp_{\log} \exp\left\{-\frac{t}{h(t)} + \log t - g(h(t))\right\} \\ &\geq \exp\left\{-\frac{2t}{h(t)}\right\}, \end{aligned} \quad (2.3)$$

which is the desired lower bound. □

## 3 Preliminaries for upper bounds

### 3.1 Reduction to tail estimate for additive functional

Let us first translate the problem in terms of the hitting time  $H(x)$  of  $x$  by our process. For any  $u > v$ , on the slowdown event  $\{X_t < vt\}$ , either the walk hit  $ut$  before time  $t$  and thereafter go back to  $(-\infty, vt]$  or it does not reach  $ut$  before time  $t$ . Hence,

$$P_0^{\omega, \mu}(X_t < vt) \leq P_0^{\omega, \mu}(H(ut) < t, X_t < vt) + P_0^{\omega, \mu}(H(ut) \geq t). \quad (3.1)$$

The first term on the right hand side is exponentially small in  $t$ . Indeed, since the random walk then must backtrack for length  $(u - v)t$ , it follows that

$$\begin{aligned} P_0^{\omega, \mu}(H(ut) < t, X_t < vt) &\leq P_{ut}^{\omega, \mu}(H(vt) < \infty) \\ &= P_{ut}^{\omega}(H(vt) < \infty) \leq \exp\{-c(u - v)t\} \end{aligned} \quad (3.2)$$

(see Lemma 3.1 for the last inequality). To handle the other term on the right side of (3.1) we utilize the following time change description of  $P^{\omega, \mu}$ . Let  $(\{S_t\}_{t \geq 0}, \{P_x^\omega\}_{x \in \mathbb{Z}})$  be the continuous time random walk in random environment, that is, it jumps after  $\text{Exp}(1)$  time regardless of its position and where it moves obeys the rule (1.1). Then, define the strictly increasing positive continuous additive functional

$$A_\mu(t) = \int_0^t \mu(S_r) dr \quad (3.3)$$

and denote by  $A_\mu^{-1}$  its inverse. Since the process  $\{S_{A_\mu^{-1}(t)}\}_{t \geq 0}$  has under  $P_0^\omega$  the same law as  $\{X_t\}_{t \geq 0}$  has under  $P_0^{\omega, \mu}$ , the second term in (3.1) is precisely

$$P_0^\omega(H(ut) \geq A_\mu^{-1}(t)) = P_0^\omega(A_\mu(H(ut)) \geq t). \tag{3.4}$$

### 3.2 Green function estimates

The Green function for  $\{S_t\}_{t \geq 0}$  is defined for  $-\infty \leq a < x < b \leq \infty$  as

$$G_{(a,b)}^\omega(x, y) = E_x^\omega \left[ \int_0^{H(a) \wedge H(b)} 1_{\{y\}}(S_r) dr \right]. \tag{3.5}$$

Since our random walk is transient, this quantity is finite  $\mathbf{P}$ -almost surely.

**Lemma 3.1.** *There exist positive constants  $c_1, c_2$  and a function  $\eta(\epsilon) \rightarrow 0$  as  $\epsilon \rightarrow 0$  that depend only on  $\mathbf{P}$ -essinf  $\omega(0) > 1/2$  such that the following hold  $\mathbf{P}$ -almost surely:*

- (i) for any  $z \in \mathbb{Z}$ ,  $E_{z-1}^\omega[\exp\{\epsilon H(z)\}] \leq 1 + \eta(\epsilon)$ ,
- (ii) for all  $x \geq y$ , both  $P_x^\omega(H(y) < \infty)$  and  $G_{(-\infty, \infty)}^\omega(x, y)$  are bounded by  $c_1 \exp\{-c_2(x - y)\}$ .

*Proof.* Let  $(\{S_t\}_{t \geq 0}, \{P_x^\omega\}_{x \in \mathbb{Z}})$  be the biased random walk corresponding to the deterministic environment  $\omega \equiv \mathbf{P}$ -essinf  $\omega(0) > 1/2$ . It is standard to construct a coupling  $(S_t, \underline{S}_t)$  so that the two walks jump at the same time and  $\underline{S}_t \leq S_t$  for all  $t \geq 0$ . The first assertion (i) readily follows from this coupling since for any  $\epsilon > 0$ ,

$$\sup_{z \in \mathbb{Z}} E_{z-1}^\omega[\exp\{\epsilon H(z)\}] \leq E_0^\omega[\exp\{\epsilon H(1)\}] =: 1 + \eta(\epsilon). \tag{3.6}$$

Next, turning to the proof of (ii), by our coupling  $P_z^\omega(H(z - 1) = \infty) \geq \eta$ , uniformly in  $\omega$  and  $z \in \mathbb{Z}^d$ , where  $\eta := P_z^\omega(H(z - 1) = \infty)$  is positive. Hence, by the strong Markov property,

$$P_x^\omega(H(y) < \infty) = \prod_{z=x}^{y-1} P_z^\omega(H(z - 1) < \infty) \leq (1 - \eta)^{y-x} \tag{3.7}$$

as claimed. Another application of the strong Markov property yields the identity

$$G_{(-\infty, \infty)}^\omega(x, y) = P_x^\omega(H(y) < \infty) G_{(-\infty, \infty)}^\omega(y, y). \tag{3.8}$$

Further, by our coupling with  $\{P_x^\omega\}_{x \in \mathbb{Z}}$ , the return probability of the process  $(S_t)_{t \geq 0}$  is bounded away from one, uniformly in its starting point  $S_0 = y$  and the environment  $\omega$ . This implies same uniform boundedness of  $G_{(-\infty, \infty)}^\omega(y, y)$ , which in view of (3.7) and (3.8) completes the proof.  $\square$

## 4 Upper bound on a good event

Let us fix  $u \in (v, v_{\mathbf{P}})$  and a regularly varying and increasing function  $M$  with  $\lim_{t \rightarrow \infty} M(t) = \infty$ . Throughout this section, we will fix  $\omega$  and  $\mu$  and assume that they satisfy the following conditions:

$$\frac{1}{M(ut)} \max_{-\epsilon t \leq z \leq ut} \{\mu(z)\} \leq 1, \tag{4.1}$$

and there exists  $\delta \in (0, 1)$  such that

$$\sum_{y \in (-\epsilon t, ut)} c_{-\epsilon t}^\omega(y) \mu(y) \leq (1 - \delta)t \tag{4.2}$$

holds for

$$c_{-\epsilon t}^\omega(y) := \sum_{x \in (y, ut]} G_{(-\epsilon t, x)}^\omega(x-1, y) \tag{4.3}$$

and all sufficiently small  $\epsilon > 0$ . Let us introduce

$$f_{\epsilon, t}(x, y) = E_x^\omega \left[ \exp \left\{ \frac{\epsilon}{M(ut)} \int_0^{H(y) \wedge H(-\epsilon t)} \mu(S_r) dr \right\} \right] \tag{4.4}$$

for  $0 \leq x < y \leq ut$ . By the strong Markov property and the fact  $f_{\epsilon, t}(x, y) \geq 1$ , this can be shown to be sub-multiplicative in the following sense: for any  $0 \leq x < y < z \leq ut$ ,

$$f_{\epsilon, t}(x, z) \leq f_{\epsilon, t}(x, y) f_{\epsilon, t}(y, z). \tag{4.5}$$

The assumption (4.1) and Lemma 3.1 imply

$$f_{\epsilon, t}(x, y) \leq E_x^\omega [\exp \{ \epsilon H(y) \}] = \prod_{z=x+1}^y E_{z-1}^\omega [\exp \{ \epsilon H(z) \}] \leq (1 + \eta(\epsilon))^{y-x}. \tag{4.6}$$

By the Feynman-Kac formula (Theorem 6.7 in [4]), we have

$$\begin{aligned} f_{\epsilon, t}(x-1, x) &= 1 + \frac{\epsilon}{M(ut)} \sum_{y \in (-\epsilon t, x)} G_{(-\epsilon t, x)}^\omega(x-1, y) \mu(y) f_{\epsilon, t}(y, x) \\ &\leq 1 + \frac{\epsilon}{M(ut)} \sum_{y \in (-\epsilon t, x)} G_{(-\epsilon t, x)}^\omega(x-1, y) \mu(y) (1 + \eta(\epsilon))^{x-y}. \end{aligned} \tag{4.7}$$

Now using  $\log(1+x) \leq x$  for  $x \geq 0$ , we obtain from (4.5) and (4.7) that

$$\begin{aligned} \log f_{\epsilon, t}(0, ut) &\leq \sum_{1 \leq x \leq ut} \log f_{\epsilon, t}(x-1, x) \\ &\leq \sum_{1 \leq x \leq ut} \frac{\epsilon}{M(ut)} \sum_{y \in (-\epsilon t, x)} G_{(-\epsilon t, x)}^\omega(x-1, y) \mu(y) (1 + \eta(\epsilon))^{x-y} \\ &\leq \frac{\epsilon}{M(ut)} \sum_{y \in (-\epsilon t, ut)} \mu(y) \sum_{x \in (y, ut]} G_{(-\epsilon t, x)}^\omega(x-1, y) (1 + \eta(\epsilon))^{x-y}. \end{aligned} \tag{4.8}$$

Next, by Lemma 3.1(ii) we have that uniformly in  $\omega, t$  and  $y$ , as  $\epsilon \rightarrow 0$ ,

$$\begin{aligned} 0 &\leq \sum_{x \in (y, ut]} G_{(-\epsilon t, x)}^\omega(x-1, y) (1 + \eta(\epsilon))^{x-y} - c_{-\epsilon t}^\omega(y) \\ &\leq \sum_{x \in (y, \infty)} c_1 e^{-c_2(x-y)} ((1 + \eta(\epsilon))^{x-y} - 1) \rightarrow 0. \end{aligned} \tag{4.9}$$

Further,  $c_{-\epsilon t}^\omega(y) \geq G_{(-\epsilon t, y+1)}^\omega(y, y) \geq 1$  (the latter being the expected first jump time of  $\{S_t\}_{t \geq 0}$  out of  $y$ ). Consequently, it follows from (4.9) that

$$\sum_{x \in (y, ut]} G_{(-\epsilon t, x)}^\omega(x-1, y) (1 + \eta(\epsilon))^{x-y} \leq (1 + \delta) c_{-\epsilon t}^\omega(y) \tag{4.10}$$

for all sufficiently small  $\epsilon > 0$ , uniformly in  $y$ . Substituting this to (4.8), we deduce thanks to (4.2) that

$$\log f_{\epsilon, t}(0, ut) \leq \frac{\epsilon(1 + \delta)}{M(ut)} \sum_{y \in (-\epsilon t, ut)} \mu(y) c_{-\epsilon t}^\omega(y) \leq \frac{\epsilon(1 - \delta^2)t}{M(ut)}. \tag{4.11}$$

Thus, using Chebyshev's inequality and recalling (3.3) and (4.4), we obtain that

$$\begin{aligned} P_0^\omega (A_\mu(H(ut) \wedge H(-\epsilon t)) \geq t) &\leq \exp \left\{ -\frac{\epsilon t}{M(ut)} \right\} f_{\epsilon,t}(0, ut) \\ &\leq \exp \left\{ -\frac{\epsilon \delta^2 t}{M(ut)} \right\}. \end{aligned} \tag{4.12}$$

Recall Lemma 3.1(ii) that  $P_0^\omega(H(-\epsilon t) < \infty)$  decays exponentially in  $t$ , so we can choose  $\epsilon > 0$  such that for all sufficiently large  $t$ ,

$$\begin{aligned} P_0^\omega (A_\mu(H(ut)) \geq t) &\leq P_0^\omega (A_\mu(H(ut) \wedge H(-\epsilon t)) \geq t) + \exp\{-c_\epsilon t\} \\ &\leq 2 \exp \left\{ -\frac{\epsilon \delta^2 t}{M(ut)} \right\}. \end{aligned} \tag{4.13}$$

Referring to Subsection 3.1, this leads us to an upper bound

$$P_0^{\omega,\mu}(X_t < vt) \lesssim_{\log} \exp \left\{ -\frac{t}{M(t)} \right\} \tag{4.14}$$

under the assumptions (4.1) and (4.2) (where we also used the fact that  $t \mapsto M(t)$  is regularly varying at infinity).

### 5 Proofs of upper bounds

*Proof of the upper bound in Theorem 1.4.* In view of (4.14), we have only to show that (4.1) and (4.2) are satisfied for a suitable  $M$  and  $u \in (v, v_{\mathbf{P}})$ . Thanks to Lemmas 1.1 and 1.2, if we choose

$$M(t) = \begin{cases} g^{-1}((1 + \epsilon) \log t), & \text{or} \\ u_\rho(t), & \text{when (1.6) holds,} \end{cases} \tag{5.1}$$

with  $\epsilon > 0$ , then (4.1) holds  $\mathbb{P}$ -almost surely for all sufficiently large  $t$ .

Let us turn to verify the second condition (4.2). Replacing  $\mu(y)$  by their mean value  $\mathbb{E}[\mu(y)] = 1$ , on the left side of (4.2), yields

$$\begin{aligned} \sum_{y \in (-\epsilon t, ut)} c_{-\epsilon t}^\omega(y) &\leq \sum_{x \in (-\epsilon t, ut)} \sum_{y \in (-\infty, x)} G_{(-\infty, x)}^\omega(x - 1, y) \\ &= E_{-\epsilon t}^\omega[H(ut)]. \end{aligned} \tag{5.2}$$

The last expression is  $\mathbf{P}$ -almost surely of size  $\frac{u+\epsilon}{v_{\mathbf{P}}}(t + o(t))$  as  $t \rightarrow \infty$ . This can be seen as follows: in the same way as in [19, (1.16)], we find that for  $\mathbf{P}$ -a.e.  $\omega$ ,  $t^{-1}H(ut) \rightarrow (u + \epsilon)/v_{\mathbf{P}}$  in  $P_{-\epsilon t}^\omega$ -probability as  $t \rightarrow \infty$ . On the other hand, by the same coupling as in the proof of Lemma 3.1, it follows that  $\sup_{t,\omega} E_{-\epsilon t}^\omega[(H(ut)/t)^2] < \infty$ . This implies the uniform integrability of  $\{H(ut)/t\}_{n \in \mathbb{N}}$  with respect to  $P_{-\epsilon t}^\omega$  for every  $\omega$ , and hence the above in probability convergence can be upgraded to the convergence in  $L^1$ .

For any fixed  $u < v_{\mathbf{P}}$ , we can choose  $\delta > 0$  such that  $\frac{u+\epsilon}{v_{\mathbf{P}}} < 1 - \delta$  for all sufficiently small  $\epsilon$ , so it remains to control the discrepancy on the left-side of (4.2) due to replacing  $\mu(y)$  by  $\mathbb{E}[\mu(y)] = 1$ . To this end, note that from Lemma 3.1-(ii) we have that the weights  $c_{-\epsilon t}^\omega(y)$  are uniformly bounded. Thus, applying the strong law of large numbers for the weighted sum of zero mean i.i.d. variables  $\{\mu(y) - 1\}$ , with such weights  $\{c_{-\epsilon t}^\omega(y)\}$  yields that  $\mathbb{P} \otimes \mathbf{P}$ -almost surely,

$$\sum_{y \in (-\epsilon t, ut)} c_{-\epsilon t}^\omega(y)(\mu(y) - 1) = o(t) \tag{5.3}$$

as  $t \rightarrow \infty$  and we are done. □

In order to prove the upper bound in Theorem 1.6, we need the following lemma, which states that (1.15) is not too far from an equality.

**Lemma 5.1.** *Let  $h(t)$  be as in (1.15). Then for sufficiently large  $t$ ,*

$$\frac{t}{h(t)} \leq 2(g(h(t)) - \log t). \tag{5.4}$$

*Proof.* We claim that for some  $c < \infty$  and all  $t$  large enough  $h(t) \leq ct/\log t$ . Indeed, for  $h(t) > ct/\log t$  the left side of (1.15) is smaller than  $c^{-1} \log t$ . On the other hand, since eventually  $g(h) \geq \beta \log h$  for some  $\beta > 1$  in all three cases (P), (I) and (W), the right hand side of (1.15) must then be at least  $\frac{1}{2}(\beta - 1) \log t$  for all large  $t$ . Thus, by (1.15) we must have  $h(t) \leq ct/\log t$  for  $c = 2/(\beta - 1)$  and all  $t$  large enough.

Now by the definition of  $h(t)$ , it follows that for any  $\lambda > 1$ ,

$$\lambda h(t)(g(\lambda h(t)) - \log t) > t, \tag{5.5}$$

which implies

$$\begin{aligned} h(t)(g(h(t)) - \log t) &> \frac{g(h(t))}{g(\lambda h(t))} \frac{t}{\lambda} + h(t) \log t \left( \frac{g(h(t))}{g(\lambda h(t))} - 1 \right) \\ &\geq \frac{g(h(t))}{g(\lambda h(t))} \frac{t}{\lambda} + ct \left( \frac{g(h(t))}{g(\lambda h(t))} - 1 \right), \end{aligned} \tag{5.6}$$

where in the second line, we have used that  $g(\cdot)$  is increasing and  $h(t) \leq ct/\log t$ . The stated conclusion (5.4) thus holds whenever

$$\lim_{\lambda \downarrow 1} \frac{g(h(t))}{g(\lambda h(t))} > \frac{c + \frac{1}{2}}{c + 1}. \tag{5.7}$$

To complete the proof, recall that for increasing and regularly varying  $g(\cdot)$  the left hand side gets arbitrarily close to one as  $h(t) \rightarrow \infty$ . □

*Proof of the upper bound in Theorem 1.6.* Again in view of (4.14) and (5.4), it remains to show that for any fixed  $u \in (v, v_{\mathbf{P}})$  and small  $\delta, \epsilon > 0$  such that  $\frac{u+\epsilon}{v_{\mathbf{P}}} < 1 - 2\delta$ , one has

$$\mathbf{P} \left( \max_{-\epsilon t \leq z \leq ut} \{\mu(z)\} > h(t) \right) \lesssim_{\log} \exp\{-g(h(t)) + \log t\}, \tag{5.8}$$

$$\mathbf{P} \otimes \mathbf{P} \left( \sum_{y \in (-\epsilon t, ut)} c_{-\epsilon t}^{\omega}(y) \mu(y) > (1 - \delta)t \right) \lesssim_{\log} \exp\{-g(h(t)) + \log t\}. \tag{5.9}$$

The bound (5.8) follows by the definition of  $g(\cdot)$  and the union bound. Turning to (5.9), recall (5.2) that the event on its left-side is contained in the union of:

$$E_{-\epsilon t}^{\omega}[H(ut)] > (1 - 2\delta)t, \tag{5.10}$$

$$\sum_{y \in (-\epsilon t, ut)} c_{-\epsilon t}^{\omega}(y) (\mu(y) - 1) > \delta t. \tag{5.11}$$

To bound the probability of (5.10) we use Jensen's inequality to find that

$$\begin{aligned} \mathbf{P} (E_{-\epsilon t}^{\omega}[H(ut)] > (1 - 2\delta)t) &\leq \inf_{\lambda} e^{-\lambda(1-2\delta)t} \mathbf{E} [\exp \{ \lambda E_{-\epsilon t}^{\omega}[H(ut)] \}] \\ &\leq \inf_{\lambda} e^{-\lambda(1-2\delta)t} \mathbf{E} [E_{-\epsilon t}^{\omega}[\exp \{ \lambda H(ut) \}]]. \end{aligned} \tag{5.12}$$

The last expression is precisely the large deviation upper bound for the hitting time, which is shown in [3] to decay exponentially in  $t$  whenever  $1 - 2\delta > (u + \epsilon)/v_{\mathbf{P}}$ . Recall

Remark 1.5 that  $t \mapsto g(h(t))$  grows sub-linearly, hence any event having exponential decay in  $t$  is negligible for the purpose of verifying (5.9). Turning to similarly control the probability of the event in (5.11) recall that the positive  $c_{-\epsilon t}^\omega(y)$  are bounded away from zero and infinity, uniformly in  $\omega$ ,  $t$  and  $y$ . Thus, standard large deviation estimates for such weighted sums yield that

$$\mathbb{P} \left( \sum_{y \in (-\epsilon t, ut)} c_{-\epsilon t}^\omega(y) (\mu(y) - 1) > \delta t \right) \lesssim_{\log} \exp\{-g(h(t)) + \log t\} \tag{5.13}$$

as claimed. Indeed, if  $\mu(y)$  has a finite exponential moment (which we have for (W), when  $\alpha \geq 1$ , see (C) in case  $\alpha = 1$ ), then the Chernoff bound yields an exponential decay in  $t$  of the probability on the left-side, whereas appealing to Remark 1.5 for the sub-linear growth of  $t \mapsto h(t)$ , in case  $\mu(y)$  has no finite exponential moments, we get (5.13) as a special case of Lemma 5.2 below.  $\square$

**Lemma 5.2.** *Let  $(\{\mu_k\}_{k \in \mathbb{N}}, \mathbb{P})$  be a family of i.i.d. mean-one random variables obeying either (P), (I) or (W) with  $\alpha < 1$ . Then, for any sequence  $\{w_k\}_{k \in \mathbb{N}} \subset [0, \kappa]$  and  $\delta > 0$ , there exists  $c < \infty$  depending only on  $\delta$ ,  $\kappa < \infty$  and  $\alpha$  (which appears in conditions (P) and (W)), such that*

$$\mathbb{P} \left( \sum_{k=1}^n w_k (\mu_k - 1) > \delta n \right) \leq \begin{cases} cn^{1-\alpha}, & \text{for (P),} \\ \exp\{-c^{-1}g(\delta n)\}, & \text{for (I) and (W) with } \alpha < 1. \end{cases}$$

Such behavior of the large deviation estimates for sums of independent random variables is well-known in the literature. However, we were not able to find results in this specific form, hence for reader’s convenience include its proof in the appendix.

### A Proof of Lemma 5.2

For case (P), suppose that the independent  $\nu_k = w_k(\mu_k - 1)$  are such that

$$A_t^+ = \sum_{k=1}^n \mathbb{E}[\nu_k^t : \nu_k \geq 0] < \infty \tag{A.1}$$

for some  $t \in [1, 2]$ . Then, by [13, Corollary 1.6] we have that for any  $y \in [(4A_t^+)^{1/t}, x)$ ,

$$\mathbb{P} \left( \sum_{k=1}^n \nu_k > x \right) \leq \sum_{k=1}^n \mathbb{P}(\nu_k > y) + \left( \frac{e^2 A_t^+}{xy^{t-1}} \right)^{x/2y}. \tag{A.2}$$

With  $c := \mathbb{E}[\mu_k^t] < \infty$  for  $t = \min\{2, (\alpha + 1)/2\} > 1$ , it follows that  $A_t^+ \leq c\kappa^t n$ . Thus, fixing  $0 < \epsilon < \delta$ , from (A.2) with  $x = \delta n$  and  $y = \epsilon n$ , we obtain that

$$\mathbb{P} \left( \sum_{k=1}^n \nu_k > \delta n \right) \leq n \mathbb{P} \left( \mu_1 - 1 \geq \frac{\epsilon n}{\kappa} \right) + \left( \frac{e^2 c \kappa^t}{\delta \epsilon^{t-1} n^{t-1}} \right)^{\delta/2\epsilon} \tag{A.3}$$

as soon as  $n^{1-1/t} \geq \epsilon^{-1}(4c\kappa^t)^{1/t}$ . The first term on the right hand side of (A.3) has the desired form while the second term there is negligible when  $\delta(t - 1) > 2\epsilon(\alpha - 1)$ .

The case (W) with  $\alpha < 1$  and (I) are studied in [11, 12] and [17], respectively, for the i.i.d. setting. Utilizing a standard truncation argument, we extend their results to our weighted case in the large deviation regime. Specifically, note first that for any  $0 < \epsilon < \delta$ ,

$$\begin{aligned} \mathbb{P} \left( \sum_{k=1}^n \nu_k > \delta n \right) &\leq \mathbb{P} \left( \max_{1 \leq k \leq n} \{\mu_k\} > \epsilon n \right) + \mathbb{P} \left( \sum_{k=1}^n \nu_k > \delta n, \max_{1 \leq k \leq n} \{\mu_k\} \leq \epsilon n \right) \\ &\leq ne^{-g(\epsilon n)} + e^{-\delta g(n)} \prod_{k=1}^n \mathbb{E} \left[ \exp \left\{ \frac{g(n)}{n} \nu_k \right\} : \mu_k \leq \epsilon n \right]. \end{aligned} \tag{A.4}$$

The first term has the desired form since  $g(\cdot)$  is regularly varying and grows faster than the logarithm. It thus suffices to show that the product term on the right of (A.4) is bounded by  $\exp\{\epsilon g(n)\}$ . To this end, recalling that  $e^x \leq 1 + x + x^2 e^\kappa$  for  $x \leq \kappa$ , whereas  $\mathbb{E}[\nu_k : \mu_k \leq n/g(n)] \leq 0$  and  $\frac{g(n)}{n} \nu_k \leq \kappa$  when  $\mu_k \leq n/g(n)$ , we deduce that

$$\mathbb{E} \left[ \exp \left\{ \frac{g(n)}{n} \nu_k \right\} : \mu_k \leq \frac{n}{g(n)} \right] \leq 1 + e^\kappa \left( \frac{g(n)}{n} \right)^2 \mathbb{E}[\nu_k^2] = 1 + o \left( \frac{g(n)}{n} \right) \tag{A.5}$$

as  $n \rightarrow \infty$  (since  $g(n)/n \rightarrow 0$  and  $\sup_k \mathbb{E}[\nu_k^2] < \infty$ ). Next,  $\nu_k \leq \kappa \mu_k$ , hence using integration by parts and the definition of  $g(\cdot)$ ,

$$\mathbb{E} \left[ \exp \left\{ \frac{g(n)}{n} \nu_k \right\} : \frac{n}{g(n)} \leq \mu_k \leq \epsilon n \right] \tag{A.6}$$

$$\begin{aligned} &\leq \mathbb{E} \left[ \exp \left\{ \frac{\kappa g(n)}{n} \mu_1 \right\} : \frac{n}{g(n)} \leq \mu_1 \leq \epsilon n \right] \\ &\leq e^{\kappa - g(n/g(n))} + \frac{g(n)\kappa}{n} \int_{n/g(n)}^{\epsilon n} \exp \left\{ \frac{g(n)\kappa}{n} r \right\} e^{-g(r)} dr. \end{aligned} \tag{A.7}$$

The first term in (A.7) is  $o(g(n)/n)$  thanks to our assumption that  $g(\cdot)$  grows faster than the logarithm. Furthermore, from the representation formula for slowly varying functions [18, Theorem 1.2], it follows that for all  $n \geq n_0(\kappa, \epsilon)$ ,

$$\frac{g(n)}{n} \kappa r \leq \frac{g(r)}{2} \quad \forall r \in [n/g(n), \epsilon n]. \tag{A.8}$$

The integral in (A.7) is thus at most  $\int_{n/g(n)}^\infty e^{-g(r)/2} dr = o(1)$  when  $n \rightarrow \infty$ . Collecting the preceding estimates, we conclude that for all sufficiently large  $n$ ,

$$\prod_{k=1}^n \mathbb{E} \left[ \exp \left\{ \frac{g(n)}{n} \nu_k \right\} : \mu_k \leq \epsilon n \right] \leq \left( 1 + \frac{\epsilon g(n)}{n} \right)^n \leq \exp \{ \epsilon g(n) \}, \tag{A.9}$$

and the proof is complete.
