Kev indicators

Single-crystal X-ray study T = 173 K Mean $\sigma(\text{C-C}) = 0.009 \text{ Å}$ Disorder in solvent or counterion R factor = 0.062 wR factor = 0.162 Data-to-parameter ratio = 14.0

For details of how these key indicators were automatically derived from the article, see http://journals.iucr.org/e.

The title compound, $[Ru(N_3)_2(C_{25}H_{22}P_2)_2]$ or cis- $[Ru(N_3)_2-(dppm)_2]$ [dppm is bis(diphenylphosphino)methane], was obtained unexpectedly from our attempts to prepare new ruthenium molecular wires using organic bridging ligands. Both the azido ligands show a triple bond adjacent to the metal.

Received 6 July 2006 Accepted 26 July 2006

Comment

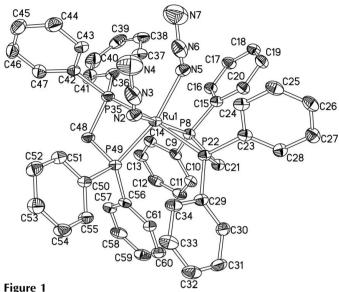

Three structures of diazidoruthenium monomeric complexes are known from the literature and in all these the two azide ligands are in the trans configuration (Siebald et al., 1996; Wehlan et al., 2000; Buys et al., 1995). In the title compound, (I), the RuII atom is in a distorted octahedral coordination environment. It is coordinated by two chelating bis(diphenylphosphino) methane ligands and two azido anions in a mutually cis geometry. Noteworthy features of the complex are the two N-N bonds adjacent to the metal, with bond lengths of 0.847 (7) and 0.823 (7) Å; this clearly defines them as triple bonds, thus locating a formal negative charge on the uncoordinated end of the azido group. 16 examples of metalcoordinated azido ligands, with N-N bonds adjacent to the metal shorter than 1 Å, can be found in the Cambridge Structural Database (CSD, Version 5.27; Allen, 2002), with refcodes AZNPNI, EBUXEE, EMOFOB, FASJAK, FIOLEX, HOJLIB, INOXAK, JAHSOA, LOZVOL, MENPUQ, NEHJEP, NEKLUK, REDKOA, WIVLOC, YETYUR and DAWTUR. There is no indication of disorder in the structure of the title complex of which the short N-N

\end{array}$$
(I)

bonds could be an artefact. Bond lengths and angles within the distorted octahedral coordination environment of the metal are reported in Table 1. Along with the neutral complex molecule, the asymmetric unit also contains dichloromethane, partially occupied and disordered about a twofold axis.

Experimental

© 2006 International Union of Crystallography All rights reserved The title complex was obtained from the reaction of a solution of trans-[RuCl(NO)(dppm)₂](BF₄)₂ (0.075 g, 0.12 mmol) and NaN₃

The molecular structure of (I) (H atoms omitted), showing the atomnumbering scheme. Displacement ellipsoids are drawn at the 30% probability level. The disordered solvent molecule has been omitted.

(0.008 g, 0.12 mmol) in 10 ml of acetone. The reaction mixture was refluxed for 2 h, then stirred for 20 h. A brown liquid fraction was removed by filtration and the recovered yellow residue dried under vacuum, washed with diethyl ether $(2 \times 5 \text{ ml})$ and dried again. Bright-yellow crystals suitable for X-ray diffraction were obtained from a dichloromethane/n-pentane (5:3) mixture.

The occupancy of the dichloromethane molecule, disordered about a twofold axis, was refined freely to 0.417 (7). Geometrical restraints were applied on the dichloromethane molecule; on the solvent molecule, as well as on the two azido ligands, displacement parameter restraints were also applied. All H atoms were refined using a riding model, with C-H = 0.95 Å for aromatic atoms, C-H = 0.99 Å for CH₂ and $U_{\rm iso}({\rm H}) = 1.2 U_{\rm eq}({\rm C})$. The maximum electrondensity peak in the final difference map lies 0.46 Å from atom N2.
