WHEN DO OFFSHORING COMPANIES LEARN FROM THE REPETITION OF FORMER ENTRY MODES?

ABSTRACT

Experience, meant as the repetition of the same action, is considered a predictor of the entry mode choice in foreign markets because it allows reducing uncertainty. However, repetition does not necessarily increase the expected performance, depending on the learning stemming from previous experiences. Focusing on offshoring decisions, namely the choice between captive and outsourcing entry mode, we distinguish between the inertial repetition of routines vs. the mindful repetition of previous entry modes (where the company distinguishes and internalizes the outcomes of the past offshoring initiatives associated to the entry choices). We claim that: (i) the latter leads to higher growth perspectives for the focal offshoring initiative, and; (ii) learning is higher when repetition concerns captive entry modes. Our empirical analysis, run on 410 companies' offshoring decisions undertaken from 2006 to 2011, confirms our expectation.

Keywords: Repeated entries; International experience; Offshoring; Outsourcing and captive entry modes.

1. INTRODUCTION

The existence of transaction costs is one of the main explanations of the traditional make-or-buy dilemma in entry mode studies involving offshoring firms. Transaction Cost Economics (TCE) argues that, when transaction costs are high, companies tend to opt for wholly owned (i.e. captive) solutions rather than arms-length contracts with external suppliers (i.e. outsourcing) (Williamson, 1975). However, different theoretical lenses are required to understand how organizations identify over time the entry mode enabling their competitiveness, as long as the TCE approach does not include learning (Teece, 2014). Moreover, the capabilities leading to competitive advantages are better explained adopting a multidisciplinary and dynamic approach (Cantwell, 2014).

With reference to the entry mode choice in foreign markets, several contributions argue that previous experience is crucial to explain subsequent entries (Chan & Makino, 2007; Chang, 1995; Chang & Rosenzweig, 2001; Erramilli, 1991; Gao & Pan, 2010; Guillen, 2003; Lu, 2002; Padmanabhan & Cho, 1999; Swoboda, Elsner & Olejnik, 2015). Indeed, experience allows companies to reduce the perceived environmental and transactional uncertainty (Anderson & Gatignon, 1986; Aulakh, Kotabe & Sahay, 1996; Benito & Gripsrud, 1992). In particular, the literature has stressed the importance of country-specific experience, which reduces the perception of the institutional and cultural distance between the home and the host country (Benito & Gripsrud, 1992; Henisz & Macher, 2004; Kogut & Singh, 1988; Tihanyi, Griffith, & Russel, 2005; Johanson & Vahlne, 1977), thus mitigating the liability of foreignness, i.e. the additional cost originating from limited knowledge of the host country (Gao & Pan, 2010). However, the connection between country-specific experience and the reduction of the liability of foreignness has been probably over-emphasized; Luo and Peng (1999) argue that country-specific experience is especially important in the start-up phases of foreign operations as long as the effect of experience on performance tends to decrease. Moreover, the mere understanding of the host country does not guarantee lasting competitiveness (Delios & Beamish, 2001; Luo & Peng, 1999) and, by definition, country-specific experience can be employed only when investing in the same country.

Experience can provide MNCs with more than the mere reduction of country-specific uncertainty. In particular, entry-specific experience, i.e. experience stemming from the repetition of the same type of entry mode, enables companies to strengthen and/or develop capabilities that are not necessarily country-specific and that can be adopted across different geographical areas. The literature identifies two different learning mechanisms that firms can take advantage of by repeating the entry mode choice (Di Gregorio, Musteen & Thomas, 2009; Gao & Pan, 2010), thus reducing uncertainty associated to liability of foreignness when investing abroad. On the one hand, repetition implies an experiential learning that strengthens the capability to set-up and manage the foreign venture, such as the ability to select, negotiate and monitor the external contractor or to organize the hierarchical and organizational architecture of the foreign subsidiaries. On the other hand, repetition can also trigger the development of new organizational knowledge, i.e. the acquisition of new routines that affect not only the management of the specific entry mode, but also the whole business model of the firm, through the transfer of the best practises from the subsidiaries and from the external suppliers to the headquarters and to the new foreign ventures.

However, we still have limited understanding of how and to what extent the repetition of previous entry mode can trigger these learning mechanisms and, ultimately, affect the outcomes of the new foreign ventures. In fact, authors studying the relationship between entry modes and outcome identify successful entries by looking at the fit between the chosen mode of entry and the predicted one (Aulakh, Kotabe & Sahay, 1996; Brouthers, 2002; Castañer, Mulotte, Garrette & Dussauge, 2013; Elia, Caniato, Luzzini & Piscitello, 2014; Leiblein, Reuer & Dalsace, 2002; Woodcock, Beamish & Makino, 1994). According to these approaches, performance is expected to increase when the firm selects the entry mode that better fits the contingencies of the actual investment based on firm's resources, transaction characteristics and local context, while overlooking the role of previous experience. To bridge this gap, we study the relationships between different types of repetition of entry mode and growth perspective of the new foreign ventures. To this end, we distinguish between inertial vs. mindful repetition, and the contingent effect of specific entry modes (captive vs. outsourcing) on this main relationship.

As regard the former, firms can repeat their previous choices ritualistically; the inertial self-imitation of previous choices is associated to learning from the process (Perkins, 2014), but it may also lead to lock-in effects, organizational inertia and -ultimately- problems of over-confidence and learning myopia (Petersen, Pedersen & Lyles, 2008). We argue that this type of repetition leads to “inertial” learning¹, where firms sticks to existing routines, thus neglecting the possibility to introduce new successful routines into the organization of the company (Levitt & March, 1988). In other terms, although inertial repetition can still trigger the reduction of liability of foreignness and the experiential learning, it is likely to prevent from the exploration of new organizational knowledge and from the adaptation of existing knowledge to new circumstances (Lewin & Massini, 2003; Lewin, Massini, & Peeters, 2011; Nelson & Winter, 1982).

By contrast, firms may identify the organizational best practices that are responsible for the past successful entry modes, and develop and adapt them to the new initiatives, as theorized by the dynamic capability approach (Teece, Pisano & Shuen, 1997; Teece, 2014). This type of repetition leads to “mindful” learning (Weick & Sutcliffe, 2006), and the growth perspective of the new foreign venture is likely to be higher than in the previous case (i.e. inertial approach).

Concerning contingencies, we consider captive vs. outsourcing entry mode, and claim that the repetition of a captive entry mode is associated to a more direct and effective transfer of information, experiential learning and organizational knowledge (Gao & Pan, 2010), while outsourcing implies the involvement of an external company, which might be less interested in transferring information. Therefore, growth perspectives of the new foreign ventures are greater in case of repetition of captive than in case of repetition of outsourcing entry modes.

In order to test our conceptual framework, we develop an empirical analysis relying on 410 offshoring initiatives involving business functions undertaken from 2006 to 2011. We distinguish between inertial and mindful repetition through a two-stage model, and find that: (i) only the latter affects positively the growth perspective of the focal offshoring initiative, and (ii) the effect of both mindful and inertial learning are larger in case of captive than in case of outsourcing entry mode

¹ Levinthal & Rerup (2006) define this type of learning as “less mindful” or “routine” learning.

Our findings add on the relationship between entry mode and experience along different lines. First, we show the relevance of previous entry-mode experience when firms choose between keeping in-house and outsourcing. Second, we disentangle different learning mechanisms associated to repetition. Additionally, we link entry choices to their future outcome by showing that mindful repetition of previous experiences leads to future higher growth perspectives than inertial repetition. Finally, we show that firms repeating captive entry mode are more likely to increase the growth perspectives of the new ventures with respect to firms repeating the outsourcing entry modes, meaning that the learning mechanisms triggered by the former are stronger than the learning mechanisms triggered by the latter.

The remainder of the paper is organized as follows. The second section illustrates the conceptual framework and, specifically, it discusses how inertial vs. mindful repetition lead to different growth perspectives, and distinguishes between repetition of outsourcing vs. repetition of captive mode. The third section presents the empirical analysis, the data and the models adopted. The fourth section illustrates the empirical results. Finally, the fifth section discusses our findings and concludes.

2. CONCEPTUAL FRAMEWORK

When facing new challenges, organizations usually rely on their former experience and often repeat their previous choices and behaviour. However, repetition of former experiences does not necessarily lead to higher performance (Argote & Miron-Spektor, 2011) as replication of, and forgetful reliance on, previous routines might be associated to an “inertial” type of learning. For example, when Norwegian authorities had to operate a sea-based oilrig for the first time, they decided to rely on their experience on ship operations; unfortunately, the safety rules that existed for ships were not adequate and the rig collapsed (March & Olsen, 1989). Individuals and organizations tend to

normalize as acceptable deviations that fit within the pre-existing routines some circumstances that would instead deserve distinctive labels² (Weick & Sutcliffe, 2006).

Conversely, behaviours involving recombination do refer to a mindful type of learning (Argote, 2006). The concept of mindfulness was originally developed in the psychological literature and refers to the individuals' state of engagement in active information processing regarding their former experiences (Weick & Sutcliffe, 2006). Similarly, in organizations, routines evolve through a process of encoding of outcomes (Levinthal & Rerup, 2006). Indeed, the routines developed in former experiences cannot be replicated as such. It is required a reflection on the differences and the similarities between past and present cases in order to adapt the existing knowledge to new projects as "the encoding of outcomes, as perceived to be successful or not, is critical to the evolution of routines" (Levinthal & Rerup, 2006: 504).

We adopt this framework to distinguish inertial vs. mindful repetition of previous entry mode choices by companies entering a foreign market.

The learning mechanisms underlying the entry-mode repetition

Repetition of the entry mode can benefit the growth perspective of a new foreign venture reducing uncertainty and, therefore, liability of foreignness. Indeed, repetition allows firms to gain specific knowledge on how to enter and operate in foreign markets by acquiring first-hand experience from ongoing operations (Gao & Pan, 2010). The repetition of the entry mode, either captive or outsourcing, enables the firm to identify the wide range of aspects that need to be taken into account when operating in foreign locations, thus reducing the level of uncertainty. Indeed, firms that have already adopted a captive entry mode can rely on the network of foreign subsidiaries to gain knowledge about international markets and business opportunities. At the same time, companies repeating outsourcing investments can glean important insights and knowledge about foreign markets thanks to the intensive interactions, personal meetings and frequent communications with the service providers, which typically characterize both the pre- and the post-implementation phases of each

² The same behaviour has been investigated at the individual level (e.g. Gersick & Hackman, 1990).

previous agreement (Di Gregorio et al., 2009). In both cases, the result is the reduction of the uncertainty associated to international investments and an increase of the alertness to international business opportunities, which translate into a decrease of the liability of foreignness. Additionally, previous entry mode can also act as a bridge to a broader network of foreign contacts, such as customers and suppliers, which might accelerate the speed to market (Murtha, 2004) and reduce the liability of outsidership (Johanson & Vahlne, 2009). As a consequence, firms can employ this knowledge to improve and to accelerate the set-up of the present offshoring initiative and to foster its future growth perspective.

Repetition allows experiential learning as firms face lower operation difficulties in setting up and managing the present foreign initiative by repeating the same entry mode already experienced before (Chang, 1995; Delios & Beamish, 2001; Gao, Pan, Lu, & Tao, 2008). Repeated outsourcing enables the firm to develop non supplier-specific routines that decrease uncertainty and accelerate processes, thus reducing transaction costs and improving trust (Aulakh, Kotabe & Sahay, 1996). A procedure to identify the proper supplier, to negotiate the agreement and to monitor its activity, for instance, can be replicated across different outsourcing initiatives involving other suppliers located in different countries (Di Gregorio et al., 2009). At the same time, a company might rely on a specific contractual form containing standard clauses (e.g. property right specifications, service level agreements etc.) that have been developed by building upon previous outsourcing experience and that are applied to every new supplier (with some degrees of adaptation). Benefits in terms of experiential learning can arise also from the repetition of captive initiatives. Indeed, wholly owned subsidiaries imply the delegation of the control of firm's assets to the management; thus, repetition allows firms to strengthen their capabilities to develop control mechanisms to align managers and owners' as well as headquarters and subsidiaries' objectives, and to design organizational and hierarchical architectures that are more efficient and effective in pursuing this goal. Hence, the gains from experience can reduce managerial uncertainty in the organization of both captive and outsourced initiatives abroad, thus increasing the probability to foster the growth perspectives of the new initiative.

Repetition also allows firms to gain knowledge that is not only specific to setting-up and managing the new foreign venture, but that involves the organization and the management of their

whole business. The intense exchange of information and the frequent interaction with the foreign subsidiary (in case of captive entry mode) and with the service provider (in case of outsourcing) provides the firm with the opportunity to absorb and integrate tacit knowledge, best practices and successful business models in their organization (Nonaka, 1994; Di Gregorio et al., 2009). Hence, firms can develop new capabilities by converting and amplifying at organizational-level the tacit knowledge arising from human interactions. Since knowledge represents the main source of a firm's competitive advantage (Nonaka & Takeuchi, 1995), this is likely to translate into an increase of the growth perspectives of the present and future initiatives. This holds true especially in international businesses, which offer the opportunity to source and combine the knowledge and the best practises from different markets (Di Gregorio, et al., 2008). For instance, after opening its subsidiary in South Korea, Wal-Mart discovered that multi-floor shops boost the sales more than single-floor shops, since customers used to spend more time inside the building. Hence, they decided to adopt the same type of strategy when opening new shops in other countries, in order to foster the growth perspectives of the new foreign initiatives (Hill, 2011). Another U.S. company used to outsource to a Korean representative the marketing of its software systems. After a request from the Korean partner, the U.S. company accepted to let the supplier not only sell but also manufacture the workstations (based on the U.S. company's components) and provide the after-sales services. This arrangement enabled the Korean partner to develop new capabilities and to offer more customized solution, and the US client to adopt a new business model, which allowed to sell more tailored products and to get rid of lower-margin installation activities (Di Greogorio et al, 2009). Previous foreign ventures represent an extraordinary opportunity to spiral the knowledge created by subsidiaries and suppliers into new organizational knowledge, thus fostering the international competitiveness of the new ventures.

Inertial vs. Mindful Repetition in Firms' Entry Mode Decision

Although repetition of previous actions can trigger the learning mechanisms discussed in the previous paragraph, we argue that inertial repetition can partially inhibit the resulting positive effects. Initiatives abroad are very costly in organizational terms, and the sunk costs tackled in past foreign ventures lead decision makers to be reluctant to switch to different solutions thus leading to lock-in

effects to previous entry choices (Mudambi, 1998). The risk of this behaviour is that firms cease to acquire knowledge from outside and merely commit and paralyze to existing routines, thus fostering organizational inertia (Cohen & Levinthal, 1990; March, 1991; Vermeulen & Barkema, 2001). Inertial repetition is likely to limit some of the potential benefits arising from previous experience, since, as suggested by Hutzschenreuter, Pedersen, and Volberda, (2007: 1057) interpreting the internationalization process model (Johanson & Vahlne, 1977), “the gradual accumulation of experience is both the limiting and the driving factor of internationalization”. The inertial self-imitation of established routines reduces the uncertainty and the operational difficulties related with international expansion through the experiential learning, but it also leads to problems of over-confidence concerning the existing routines and learning myopia, which are likely to limit the development of organizational knowledge and innovation (Petersen et al., 2008).

By contrast, when firms adopt a mindful repetition, they employ the experience gained in the past to further develop their skills and support the growth perspectives of the new foreign ventures. That happens when companies adapt their organizational and managerial capabilities from the past to the present context. This perspective relies on the assumption that the ownership of knowledge is not sufficient *per se* to foster performance, requiring to be complemented with a proactive process of capability building where firms re-process the knowledge and apply it to the new contexts (Tallman, 2003; Teece, 2014). Firms replicating the entry mode after discerning the outcome of previous foreign ventures are able to acquire the knowledge and information regarding the routines that are responsible for success and failures of past initiatives across different functions and countries. The knowledge acquired is then employed by the firm to identify the most promising investment projects and select the organizational routines enabling the success of the new entry. Finally, after selecting the project, the company fits and adapts its existing knowledge to the purposes of the new venture, thus replicating former entries.

The internationalization of Wal-Mart provides an interesting example of how this company adopted a mindful learning approach, by improving and adapting progressively its business model when repeating the (captive) entry mode. Wal-Mart learnt not only from its successes, as in the case of the Korean multi-floor shops, but also from its failures. After opening the first shop in Mexico,

Wal-Mart realized that it was no possible to replicate the U.S. business model, which was based on a very efficient logistics, a strong bargaining power with the suppliers, and the marketing of products complying with the tastes of the U.S. costumers. Indeed, the Mexican logistics and infrastructures were not as developed as in the U.S.; additionally, Mexican suppliers were not willing to grant discounts due to the underdeveloped distribution network of Wal-Mart shops in Mexico; finally, Mexican tastes were very different from the U.S. tastes. After that experience, Wal-Mart changed and adapted its business model when opening new shops in foreign countries, by establishing strategic partnership with logistics companies and local suppliers in the host countries, and by adapting the products to the local tastes (Hill, 2011). Therefore, the mindful repetition of the entry mode, based on the identification of past successes and failures, is probably one of the key factors underlying the successful internationalization of Wal-Mart, which was able to foster the growth perspective of its new ventures by exploiting the creation of new organizational learning from past experiences.

A mindful learning can, hence, become a self-generating process where firms that have learnt how to gain from previous successes and failures will continue to do so at an increasing rate (Cohen & Levinthal, 1990), and the growth of the present and future initiative is fostered by the incremental improvement of managerial and organizational capabilities (Chang, 1995). This means that the mindful repetition of the entry mode is expected to enhance the growth perspective of the present initiative more than the inertial repetition. Therefore, we expect the following first hypothesis to hold:

Hypothesis 1: A mindful repetition of the entry mode choice increases the growth perspective of the present offshoring initiative more than an inertial repetition of the entry mode choice.

Captive vs. Outsourcing Repetition in Firms' Entry Mode Decision

So far, we discussed about the mechanisms underlying the inertial and mindful repetition of captive vs. outsourcing initiatives. We now stress such peculiarities by claiming that these two different entry modes can affect the extent to which the learning mechanisms underlying inertial and mindful repetition benefit the growth perspective of the focal venture.

According to TCE, outsourcing solutions involve two or more firms, and the management and control of activities require coordination and consensus among partner organizations, but solutions are typically associated to a lower resource and operational involvement than in hierarchical modes. The latter, instead, are managed and controlled by a single entity, entail higher commitment, tighter control and larger risks, but eliminate the need to gain cooperation and consensus from other firms (Brouthers and Brouthers, 2003). This implies that firms adopting a captive entry mode are more likely to acquire intensive and direct information flows, and to leverage their own learning-by-doing and task-specific experience in subsequent entries (Pan & Tse, 2000; Foss & Pedersen, 2002). Firms repeating a captive entry mode can nurture a process of learning by leveraging their network of subsidiaries, which can transfer both their knowledge about foreign markets and their best organizational practises directly to the headquarters and to the other subsidiaries through intranet platforms, frequent meetings, job turnover etc. Additionally, hierarchical and managerial fiat can be easily implemented to foster the full adaptation of the new practises within the company and, above all, in the new foreign venture, thus maximizing the effects of the acquired learning (Larsen & Lyngsie, 2017).

Conversely, the involvement of external companies make the transfer of knowledge in outsourcing initiatives less immediate and less straightforward (Gao & Pan, 2010). As such, the learning mechanisms discussed above (related both to the strengthening of existing capabilities, and to the development of new capabilities) are likely to be less effective when repeating an outsourcing than when repeating a captive entry mode. The supplier of an outsourcing initiative, for instance, might provide no useful information about how to operate in foreign markets, thus reducing the effectiveness of the learning mechanisms that decrease the liability of foreignness. Additionally, the contribution of experiential learning might be weaker in case of outsourcing than in case of captive experience due to the continuous change of partner, which requires a higher level of adaptation to the specific agreement and, hence, a lower possibility to reuse the past knowledge. Finally, the supplier might be reluctant to transfer its knowledge and best practices to the partner; at the same time, the client might have not sufficient absorptive capacities to learn from the external company. As a consequence, also the organizational-level learning mechanism might be less effective in case of

outsourcing than in case of captive entry modes. Of course, outsourcing partners might engage in a long-term relationship based on detailed contracts specifying all the obligations and rights aiming at reducing all these incidents (Larsen & Lyngsie, 2017), given that “a long-term contract that specifies the terms and conditions for some set of future transactions *ex-ante*, provides a vehicle for guarding against *ex-post* performance problems” (Joskow, 1987: 169). However, this approach is likely to increase the initial transaction costs, thus reducing the short-term profitability of the new foreign venture. Additionally, due to the high intangibility and specificity of knowledge, it is difficult to define extensive agreements and to design complete contracts, meaning that *ex-post* problems affecting the growth perspective might arise. Following this reasoning, we formulate our second hypothesis as follows:

Hypothesis 2: The inertial and the mindful repetition of the entry-mode choice have a more positive effect on the growth perspective of the present offshoring initiative when repeating a captive entry-mode than when repeating an outsourcing entry-mode.

3. EMPIRICAL STUDY

3.1. The Context and the Sample

To test our conceptual framework, we use the context of business functions offshoring. The offshoring phenomenon typically regards manufacturing and production activities delocalized to emerging economies (either through captive or through outsourcing entry modes) in order to exploit cost advantages, as long as knowledge-intensive activities are traditionally located in advanced countries' headquarters (Contractor, Kumar, Kundu, & Pedersen, 2010). However, the standardization of complex tasks, the improvement of the capabilities in emerging economies and the advances in ICT have led to increasingly offshore to developing countries also high value-added business functions such as engineering services, product development and R&D (Lewin, Massini, & Peeters, 2009; Manning, Massini, & Lewin, 2008). The underlying drivers are shifting accordingly from cost

reduction to strategic resource achievement, meaning that firms need to source knowledge from abroad in order to improve their competitiveness. Therefore, the analysis of the relationship between entry-specific experience and outcome becomes extremely relevant for business functions offshoring, since firms are involved in sequential investments that require an increase of organizational capabilities through a process of knowledge recombination across different offshoring initiatives.

We employ the dataset developed by the Offshoring Research Network (ORN) survey, which inquires the offshoring of business functions including knowledge intensive activities (e.g. engineering services, product development and R&D). This is one of the most comprehensive initiative for studying offshoring of business services by companies of varied size, in a wide range of industries and countries (Elia et al., 2014; Lewin & Peeters, 2006; Lewin et al., 2009).

ORN initiated thanks to the Centre for International Business Education and Research (CIBER) of Duke University in the United States, with the participation of an international network of researchers and practitioners counting 13 partner universities and business schools belonging to the following countries: Australia, Belgium, Brazil, China, Denmark, Germany, France, Italy, Japan, Korea, the Netherlands, the United Kingdom, and Spain. Each partner collected data on offshoring of business functions administrative services in their own country and shared them with the other members of the network, thus contributing to the ORN database.

The ORN program tracked global sourcing strategies, drivers, geographic dynamics, risks, entry mode, performance and plans across all industries and business functions through a detailed questionnaire about administrative and technical work from abroad. The respondents to the ORN survey are managers of the companies that implemented the offshoring initiatives. The survey was sent to a top manager (e.g. CEO, CFO, etc.) of listed companies by email with the request to pass it to colleagues with expert information about offshoring initiatives and reshoring plans of his/her company. The ORN database builds on six repeated surveys starting in 2005; the last survey was administered in 2011.

This dataset benefits from including a remarkably high number of home countries, which reflects the geographic areas covered by ORN partners, whose headquarters are mostly located in the European and US areas. The offshoring flows are directed towards advanced, emerging and

developing countries. The original ORN project was designed to study the offshoring phenomenon using an original comprehensive survey, which covered most aspects of the offshoring of business services at the level of the individual implementation. Therefore, despite some limitations related to the unavailability of panel data, we find that the ORN dataset is a valuable source to study the repetition of the entry modes of offshoring companies given that, for each firm, we are able to assess the sequence of the offshoring initiatives having the information about the year of implementation for each venture.

In order to include some factors related to the role of the macro-economic performance, the institutions and the culture of the host country, we integrated the ORN database with other three datasets: (i) the World Competitiveness Yearbook; (ii) the World Bank, and (iii) Hofstede (2001)³. The latest release of the ORN dataset issued in 2011 records 5,619 observations; however, as we focus on the offshoring initiatives with previous experiences, the number of observations in our econometric investigation amounts to 410 (belonging to 138 companies), also due to missing values in some of the variables considered. More than 66% of the firms have their headquarters in the United States and Canada; the rest of the firms have their headquarters in Europe or Australia (table 1). The host country with the highest percentage of offshoring initiatives is India (around 34%, table 2). Regarding business functions, the ones with highest percentage of offshoring ventures are the Customer Contact and the Information Technology (both with a percentage of around 18%, table 3). The software and IT service is the industry with the highest percentage of offshoring initiatives with a percentage of almost 26% (table 3).

3.2. Methodology

³ The combination of the ORN survey with external databases is also useful to limit the Common Method bias.

The literature has already shown that the relationship between entry mode and outcome can be potentially affected by self-selection and endogeneity problems resulting from underlying omitted and unobserved factors influencing both strategy choice and performance. Indeed, managers typically select the entry mode of a foreign venture having a specific outcome in mind, meaning that, on the one hand, the ultimate outcome is conditional upon unobserved factors that influence firms' modes of entry; on the other hand, the entry mode turns out to be affected by the expected outcome. As long as statistical analyses not accounting self-selection process can suffer from biased estimations, we adopted a two-step selection approach *à la* Heckman (1979). This technique is probably the most established methodology in the literature when assessing the relationship between the entry mode and an outcome variable and which enables to obtain consistent and unbiased estimates (Brouthers, 2002; Castañer et al., 2013; Elia et al., 2014; Leiblein et al., 2002; Shaver, 1998)⁴. Specifically, in the first stages, we estimate a probit model in which the entry mode (outsourcing versus captive) is the dependent variable, and it is regressed against a set of variables identified in the literature.

Accordingly, in step (1) we assess the relationship between the entry mode and a set of variables, including the repetition of previous entry modes:

$$\text{Entry mode} = f(\text{repetition of previous entry modes, controls}, \varepsilon) \quad (1)$$

We then compute the entry-fit, i.e. the fit between the entry mode predicted by step (1) and the entry mode selected by the companies in our samples for each offshoring initiative. The entry-fit allows assessing the extent to which the entry choice of each foreign venture is based on a model driven by the repetition of previous entry modes. In step (2), we include the entry-fit as a main explicative variable, in order to investigate whether and how the outcome of the focal offshoring initiative is affected by an entry choice based on repetition:

⁴ An instrumental variable approach controlling for the endogeneity underlying the entry mode choice could also be employed as alternative technique. However, in order to account also for the self-selection bias, we opted for a two-stage approach *à la* Heckman, which, indeed, is the most popular methodology employed in this literature.

$$Outcome = f(entry_fit, controls, \mu) \quad (2)$$

To test our conceptual framework, we run the two-step methodology twice. Indeed, through the first step we estimated two alternative models: (a) an “inertial entry choice model”, i.e. an entry model based on the inertial repetition of past entry modes; (b) a “mindful entry choice model”, i.e. an entry model based on the mindful repetition of past entry modes. The inertial repetition of past entry modes has been captured by assessing the impact on the actual entry mode (e.g. outsourcing) arising from the former entries of the same type (i.e. outsourcing) and from the former entries of the opposite type (i.e. captive). We consider as an evidence of inertial repetition when, in the first step of model (a), the outsourcing (captive) entry mode is fostered by the past outsourcing (captive) offshoring initiatives, regardless of their past performance.

The mindful repetition of past entry modes is still assessed as the impact on the actual entry mode arising from the entries of the same vs. opposite type, but after distinguishing between the growing versus the non-growing initiatives. We consider as an evidence of mindful repetition when, in the first step of model (b), the outsourcing (captive) entry mode is fostered by the past successful outsourcing (captive) offshoring initiatives. Indeed, the literature has shown that organizational learning is measured through changes in the characteristics of performance (Argote & Epple, 1990; Dutton & Thomas, 1984), and that knowledge and learning translates into greater growth perspectives and further investments. This means that past growing outsourcing (captive) experiences are the result of a process of mindful learning, and that the latter can trigger a mindful entry choice model as long as it is able to positively affect the probability to undertake an outsourcing (captive) entry mode in the first step.

In this way, we are able to distinguish between the inertial entry choice model, where former initiatives are ritualistically iterated without considering the former outcome, and the mindful entry choice model, where former initiatives are iterated once allowed for the former outcome. Specifically, in step (1), equations (1.a) estimates the inertial entry choice model (a), while equation (1.b) concerns the alternative mindful entry choice model (b):

$$\text{Entry mode} = f(\text{inertial repetition of previous entry modes, controls, } \varepsilon_1) \quad (1.a)$$

$$\text{Entry mode} = f(\text{mindful repetition of previous entry modes, controls, } \varepsilon_2) \quad (1.b)$$

Accordingly, two entry-fits have been estimated and two different equations have been employed also in step 2. Specifically, equation (2.a) investigates the impact of the entry fit arising from equation (1.a), i.e. the inertial entry fit, while equation (2.b) considers the entry fit arising from equation (1.b), i.e. the mindful entry fit:

$$\text{Outcome} = f(\text{inertial entry fit, controls, } \mu_1) \quad (2.a)$$

$$\text{Outcome} = f(\text{mindful entry fit, controls, } \mu_2) \quad (2.b)$$

The inertial entry fit captures the extent to which each offshoring initiative complies with the inertial entry choice model (a), and equation 2.a how this affects the outcome of the present offshoring initiative. Conversely, the captive entry fit captures the extent to which each offshoring initiative complies with the mindful entry choice model (b), and equation 2.b how this affects the outcome of the present offshoring initiative⁵. Figure 1 provides a representation of the empirical methodology employed in our paper.

- Insert figure 1 about here -

In the next paragraphs we illustrate in details the dependent, explanatory and control variables employed in the two equations of each step.

⁵ It is worth noting that the variable *Outcome* employed as dependent variable in step 2 refers to the current initiative, while the variable *Outcome* employed in equation 1.b refers to the former experiences. Additionally, the variable *Outcome* has not been employed directly in equation 1.b but only to distinguish between growing and not growing initiatives. Of course, we are aware that using lagged value variables can only alleviate the endogeneity issue but it may not solve it completely.

3.3 Variables of Step (1)

Dependent variable. The dependent variable in both equation (1.a) and (1.b) is the entry mode, i.e. a dummy (*Outsourcing*) which assumes value 1 for outsourcing (i.e. international, local or domestic third-party service provider), and 0 for captive (i.e. wholly-owned subsidiary). The variable is obtained from the following question in the ORN survey: “What is the service delivery model currently used for this offshoring implementation?”. The number of captive (51.46% of the sample with 211 observations) and outsourcing (48.54% of the sample with 199 observations) initiatives is quite balanced.

Explanatory variables. The main explanatory variables employed in the equations of step (1) refer to the repetition of previous entry modes, which relies on the count of the times the two alternative types of entry modes have been already adopted by the company (Chan & Makino, 2007; Chang, 1995; Dikova & Van Witteloostuijn, 2007; Gao & Pan, 2010; Guillen, 2003; Lu, 2002).

Specifically, in order to proxy the inertial repetition of previous entry modes, we define *Repeated Captive Experience* and *Repeated Outsourcing Experience* as the number of previous captive and outsourcing initiatives, respectively.

Likewise, to account for the mindful repetition of previous entry modes, we distinguished between *Repeated Growing Captive Experience*, *Repeated Growing Outsourcing Experience*, *Repeated Non-Growing Captive Experience* and *Repeated Non-Growing Outsourcing Experience*. The first two variables refer to the number of previous captive and outsourcing initiatives for which the respondent to the ORN questionnaire is expecting some growth perspectives, while the latter refer to previous captive and outsourcing experiences for which no growth is expected. Specifically, we counted the number of past captive and outsourcing experiences that were and were not planned to be expanded in the next three years, based on the answer to the question: “What are the plans for this implementation for the next three years? Expand the activities in the current offshore location: yes or no?”. When the answer is “yes”, we consider it as a growing experience, when the answer is “no”, we

consider it as a non-growing experience. Hence, these variables introduce in the count of previous offshoring ventures an assessment of their outcome, thus reflecting a mindful attitude in the replication of previous entry modes.

Table 4 provides an example of the procedure employed to build the explicative variables of equations 1.a and 1.b.

- Insert table 4 about here -

Control variables

We introduce *Country-specific experience* as a first control, in order to wipe off the country-specific effect (i.e. the effect arising from the repetition of the investment in the same host country) from the entry-specific experience. This variable accounts for the number of times the company has already invested in the host country during past offshoring initiatives. In our sample, 46.5% of deals involve firms with no previous country-specific experience, while the remaining deals have a number of previous investments in the same country ranging from 1 (28% of the sample) to 7 (0.73% of the sample).

As regards the other controls, the literature suggests that offshoring is a complex phenomenon, which needs to be investigated at different levels of analysis (Hätönen & Eriksson, 2009; Oshri, Kotlarsky & Willcocks, 2015). Therefore, we introduced firm-level, function-level, industry-level, country-level and deal-level control variables that are likely to affect the entry mode of the foreign offshoring ventures. We employ the same controls in equations (1.a) and (1.b).

As regards the firm-level variables, we adopted a discrete measure of firms' size as long as ORN questionnaires collected categorical instead of continuous data: the dummy variable *Small Firms* (less than 500 employees) is the default, while the other two dummy variables account for *Medium Firms* (between 500 and 20,000 employees), and *Large Firms* (those with more than 20,000 employees). *Small Firms* account for 21.95% in our sample, *Medium Firms* for 36.59% and *Large Firms* for 41.46%. It is worth noting that the firms included in the ORN survey are quite large and this is the reason why the thresholds set for our size dummies are equally large.

We then control for the functions and the industries. Specifically, we introduce a dummy variable, named *High Value Added Functions*, which distinguishes between high value-added activities (Product Design, Engineering Services and Research & Development) and the remaining ones (Software Development, Call Centres, Finance and Accounting, Human Resources, Information Technology, Knowledge Services, Legal Services, Marketing and Sales and Procurement)⁶. Also, a standard industry control is included through a dummy variable named *IT Sector*, in order to account for the numerous ICT firms in the sample that have offshored especially in India, one of the top destinations for ICT industry due the large availability of service providers and skilled human resources (Pereira & Malik, 2015).

As regards the country-level variables, we first control for the *Cultural Distance* between the home and host country involved in each deal, by employing the formula suggested by Kogut and Singh (1988), and based on Hofstede (2001) items⁷. Higher cultural distance is associated to higher uncertainty, which, on the one hand, might discourage a full commitment thus favouring an outsourcing solution but, on the other hand, it also implies higher transaction costs and, hence, a larger probability to select a captive entry mode. We also control for the institutional context and macro-economic performance of the host countries, which have been suggested to play a crucial role in the offshoring decisions by affecting the quality of resources, knowledge, skills and talent (Peng, Sun, Pinkham, & Chen, 2009), through the variables *Governance Infrastructure* and *Market Attractiveness*, respectively (Globerman & Shapiro, 2003). Both these variables are the result of a factor analysis implemented respectively on World Governance Indicators databases (source: World Bank) and the World Competitiveness Yearbook using only the average of the data between 2004 and 2011 (the years of the survey). Table 5 provides further details regarding the construction of these variables and the underlying items. Additionally, we accounted for firms having the US as home

⁶ This variable has been built following Youngdahl, Ramaswamy, & Dash (2010).

⁷ The items included in the measure of cultural distance are the followings (Hofstede, 2001): Power Distance Index (PDI), Individualism versus Collectivism (IDV), Masculinity versus Femininity (MAS), Uncertainty Avoidance Index (UAI), Long Term Orientation versus Short Term Normative Orientation (LTO), and Indulgence versus Restraint (IND).

country by employing a dummy variable named *Home country United States*, as long as the majority of the firms in the sample belong to this country.

- Insert table 5 about here -

Finally, deal-level controls have been included by looking at the strategic drivers of each investment through the variables *Access to Qualified Talents*, *Labour Cost*, *Colocation of Manufacturing* and *Market Penetration*, which are based on a 1 to 5 Likert scale (source: ORN survey). The first two variables enable to understand if the deal is driven by resource-seeking or cost-saving purposes, respectively, while the third one signals if the investment is connected with other investments already implemented in the area and the fourth one captures if the venture has been implemented to penetrate new markets abroad. These variables enable us to better account for the complex nexus between locations, motivations and disintegration arising from offshoring, which have been highlighted to be crucial to understand the offshoring phenomenon by several scholars (Hätönen & Eriksson, 2009; Oshri, Kotlarsky & Willcocks, 2015). Moreover, we account for the duration of each offshoring venture using the variable *Age of the Initiative*, computed as the difference between the year of the survey (i.e. 2011) and the year of the implementation of the deal.

3.4 Variables of Step (2)

Dependent variable. Growth Perspective is the dependent variable of both equations (2.a) and (2.b); it is measured as the company's intention to increment the activities at the current offshore location in the next three years (the relevant question in the ORN survey is: "What are the plans for this implementation for the next three years? Expand the activities in the current offshore location: yes or no?"). The variable assumes value 1 when it is forecasted an expansion of the offshoring venture, and 0 otherwise. The number of initiatives with growing perspectives in our sample is 234 (57.07%).

It is worth noting that our dependent variable is a perceptual measure. Subjective measures have been largely employed as non-financial performance (Brouters, 2002), also in studies about

offshoring ventures (Hult et al., 2008; Martin, 2013). Even if subjective indicators suffer of social desirability bias, as long as respondents to surveys tend to reply in a manner that will be viewed favourably by other people, the adoption of financial data to assess firm's performance might be biased by short-run contingencies. Furthermore, some major issues challenge the adoption of objective performance measures in international business. Indeed, (i) companies are reluctant to provide objective data regarding their foreign subsidiaries; (ii) some offshoring ventures are not undertaken in order to obtain financial gains; (iii) it is not easy to convert data stemming from several countries and companies into a common and consistent unit of measure. Additionally, the relevance of the growth perspective as a key variable capturing the performance was remarked by Kaplan and Norton (2001)⁸. The authors state that financial measures are not sufficient to assess the performance of a firm, due to the reasons explained above. Therefore, they propose a "Balanced Scorecard" methodology, which relies on interviews and discussions with senior executives and which is based on the evaluation of four different dimensions, including the "learning and growth perspectives". This relationship, which represents the core of our paper, is considered the most important dimension of the performance assessment, being the foundation of any strategy, since "in the learning and growth perspective, managers define the employee capabilities and skills, technology, and corporate climate needed to support a strategy" (Kaplan & Norton, 2001, p.94).

Explanatory Variables. Following previous studies (e.g. Leiblein et al., 2002), we computed from both equations of step (1) the entry-fit between the predicted entry mode and the entry mode selected by companies as a continuous variable (ranging from 0 to 1), equal to Φ in case of outsourcing and to $1 - \Phi$ in case of captive, where Φ is defined as the standard normal cumulative distribution function, as follows:

$$\text{Prob}(Y_i = 1) = \Phi(\beta'X_i)$$

⁸ The paper by Kaplan and Norton (2001) was published in the journal "Accounting Horizons", which is part of the American Accounting Association.

We named *Inertial Entry Fit* the entry-fit computed from equation (1.a) and *Mindful Entry Fit* the entry-fit computed from equation (1.b). The main advantage of computing two entry fits is that they allow identifying and distinguishing effectively the offshoring initiatives based on an inertial entry choice model and the offshoring initiatives based on a mindful entry choice model. The inertial and mindful entry fits have been introduced as main independent variables in equations (2.a) and (2.b), respectively⁹. According with hypothesis 1, we expect *Mindful Entry Fit* to have a stronger impact on growth perspective than *Inertial Entry Fit*.

Following the literature assessing the relationship between entry mode and performance (Brouthers, 2002; Castañer et al., 2013; Elia et al., 2014; Leiblein et al., 2002; Shaver, 1998), we also introduced the dependent variables of step (1), i.e. *Outsourcing*, as explicative variable of step (2). This variable enables to investigate whether the entry mode (beside the entry-fit) has both a direct impact on the growth perspective and a moderating effect on the inertial and mindful entry fits. In order to test the latter, we adopted two alternative methods. On the one hand, we introduced the interaction term between outsourcing and inertial entry fit in equations 2.a and between outsourcing and mindful entry fit in equation 2.b. On the other hand, following the recommendation by Greene (2010) and Gooris and Peeters (2016)¹⁰ and following the literature on entry modes and performance (see, e.g. Leiblein et al., 2002), we also split equations 2.a and 2.b in two subsamples, one accounting for outsourcing and one accounting for captive initiatives. Based on hypothesis 2, we expect a negative moderation effect of outsourcing on both entry fits (when using the interaction term) and a stronger positive effect of inertial and mindful entry fit in case of captive than in case of outsourcing initiatives (when using subsamples).

⁹ It is worth noting that using two separate equations not only enables us to estimate two alternative repetition entry choice models, i.e. the inertial (a) and the mindful (b) ones, but also to avoid multicollinearity problems both in the first and in the second step. Indeed, the explicative variables employed in equation 1.a, which distinguishes between previous captive and previous outsourcing entry modes, are linear combination of the variables employed in equation 1.b, where each captive and outsourcing initiative is further sliced into growing and not growing initiatives. At the same time, running only once the second step would imply to use two different entry fits, i.e. the inertial and the mindful one, in the same equation, which is likely to give birth to a further multicollinearity problem, given that the entry fits are computed from two models whose key variables are linearly dependent one from each other.

¹⁰ Greene (2010) suggests that the estimation technique based on interaction in non-linear models is “generally uninformative and sometimes contradictory and misleading”. Therefore, he recommends dealing with interaction effects through model design (which, as in Gooris and Peeters, 2016, can be addressed through the use of subsamples) rather than employing interaction coefficients.

Control variables. We employed in both equations of step (2) the same control variable of step (1)¹¹. The table in the appendix provides further information regarding all the variables adopted and their construction.

Table 6 provides the correlation matrix and some descriptive statistics of the dependent, explanatory and control variables employed in the equations of steps (1) and (2), in order to check for possible multicollinearity issues. However, none of the relationships appears to be large enough to warrant concern for multicollinearity. We also computed the Variance Inflation Factors (VIFs) for both equations of each step. None of the values is above the threshold of 10.00, thus ruling out potential multicollinearity problems.

4. RESULTS

4.1 Findings

Given the nature of the dependent variables, we employ Probit models using a robust variance estimator in both Step (1) and Step (2). Table 7 shows the results concerning hypothesis 1. Namely, columns 1.a and 1.b are associated to Step (1), as they report the coefficients of the estimation of equations (1.a) and (1.b), respectively, while columns 2.a and 2.b are associated to step (2), as they show the results of the estimation of equations (2.a) and (2.b), respectively.

¹¹ The two-step methodology adopted in this paper requires at least one excluded explanatory variable that influences step (1) and not step (2). Our exclusion restrictions are the variables *Repeated Captive Experience* and *Repeated Outsourcing Experience* in equation 1.a, and *Repeated Growing Captive Experience*, *Repeated Growing Outsourcing Experience*, *Repeated Non-Growing Captive Experience* and *Repeated Non Growing Outsourcing Experience* in equation 1.b.

Estimates for Step (1) confirm the temporal interdependence of entry choices (Chan & Makino, 2007; Chang & Rosenzweig, 2001; Guillen, 2003; Lu, 2002; Padmanabhan & Cho, 1999; Swoboda et al., 2015). Indeed, the variables reflecting the captive past entry modes show negative and significant coefficients, i.e. *Repeated Captive Experience* with a coefficient of -0.167 ($p < 0.01$) (column 1.a), and *Repeated Growing Captive Experience* with a coefficient of -0.305 ($p < 0.001$) (column 1.b). Conversely, the variables reflecting the outsourcing past entry modes, i.e. *Repeated Outsourcing Experience* (column 1.a) and *Repeated Growing Outsourcing Experience* (column 1.b), display positive (respectively 0.213 and 0.362) and significant ($p < 0.001$ in both cases) correlations with the dependent variable. Therefore, results confirm that firms tend to replicate the previous entry modes of the same type. In particular, the mindful entry-choice model shows that firms tend to repeat the past successful experiences.

In step (2), we find that the variable *Inertial Entry Fit* is not statistically significant ($p = 0.276$) (column 3). Conversely, the variable *Mindful Entry Fit* is statistically significant with a positive sign ($p = 0.022$) and a coefficient of 0.642 (column 4), thus signalling that offshoring firms relying on mindful repetition of their entry modes foster the growth perspectives of their initiatives more than offshoring firms relying on inertial repetition of their entry modes¹². Firms analysing their previous experiences and their success drivers, indeed, are able to foster learning and develop knowledge and, ultimately, enhance the growth perspective of their offshoring initiatives over time. Hence, our hypothesis 1 is fully verified.

Regarding the control variables in step (1), we find that country-specific experience increases the probability of undertaking captive entry modes ($p < 0.001$), as suggested by the traditional stage theories (e.g., Johanson & Vahlne, 1977). As firms gain familiarity with the host country, they face a lower liability of foreignness, thus increasing the level of commitment through captive entry modes. It also turns out that larger firms ($p < 0.05$) and firms operating in IT industries ($p < 0.001$) are more likely

¹² We performed a post-estimation Chi-Square test in order to verify whether the coefficient of the variable *Inertial Entry Fit* is significantly different from the coefficient of the variable *Mindful Entry Fit*. The test rejects the null hypothesis that the difference between the two coefficients is equal to zero (Chi-square=8.923, p-value=0.0028), thus confirming that the mindful entry fit has a significantly larger effect on growth perspective than the inertial entry fit.

to undertake captive investments, probably due to the high amount of resources required by the latter and to the need of IT firms to keep a tight control of foreign operations for security and quality reasons. Additionally, results show that outsourcing initiatives are less likely in countries with high cultural distance ($p < 0.01$ in column 1.a and $p < 0.05$ in column 1.b) and high governance infrastructure ($p < 0.001$), since familiar and stable environments enable firms to invest with a higher commitment. Conversely, outsourcing seems to be more likely if the home country is the U.S. ($p < 0.05$ in column 1.b). Finally, captive investments are more likely in case of colocation of manufacturing firms ($p < 0.01$ in column 1.a and $p < 0.05$ in column 1.b) - probably because synergies across activities are better managed through vertical integration - and when the main driver is market penetration ($p < 0.10$) – probably because captive investments enable a higher rent appropriation.

As regards the control variables in step (2), the outsourcing mode of entry ($p < 0.001$), the cultural distance ($p < 0.10$), the governance infrastructure ($p < 0.001$) and the age of the initiative ($p < 0.001$) reduce the likelihood of an expansion of the offshoring venture. Therefore, results suggest that an increase in growth perspective is more likely in the case of captive mode of entry. Additionally, results show that greater cultural distance reduces the likelihood of an expansion of the foreign venture, and that long-established offshoring ventures are subject to exploitative behaviours. As regards the governance infrastructure, it is likely that this variable captures stable business environments that are not subject to companies' expansion plans, which explains the negative sign ($p < 0.001$). Finally, firms driven by the access to qualified talents ($p < 0.001$) and by labour cost reduction ($p < 0.05$) are more likely to expand their businesses. In the first case, the positive correlation is probably related with the aspiration to achieve new resources typical of expanding firms, while, in the second case, it is connected with the need to obtain greater economies of scale.

- Insert table 7 about here -

Table 8 shows the results concerning hypothesis 2. Columns 1 and 2 introduce the interaction term in equations 2.a and 2.b, columns 3 and 4 split equation 2.a between outsourcing and captive subsamples, respectively, and columns 5 and 6 split equation 2.b between outsourcing and captive subsample, respectively.

Both interaction terms show a negative coefficient (columns 1 and 2), although only the interaction between outsourcing and inertial entry fit turns out to be significant ($p < 0.05$). Given the non-linearity nature of our model, we plotted the results in order to gain more insights on the moderation effect. Figure 2.a shows the interaction between outsourcing and inertial entry fit, while figure 2.b the interaction between outsourcing and mindful entry fit. The former clearly shows that the effect of inertial entry fit is positive only in case of captive entry mode, while becoming negative in case of outsourcing; conversely, the latter shows that mindful entry fit is simply more positive in case of captive than in case of outsourcing entry mode. The analyses on subsamples confirm that the inertial ($p < 0.05$) and mindful ($p < 0.01$) entry fits have a positive and significant effect on growth perspective only in case of captive (columns 4 and 6) initiatives, while the same effect is not significant in case of outsourcing initiatives (columns 3 and 5). Hence, hypothesis 2 turns out to be verified, although with a stronger effect for the inertial than for the mindful repetition.

- Insert table 8 about here -

4.2 Robustness check and additional analysis

We conducted additional robustness checks in order to verify the reliability of our results. More specifically, we replicated the second step using as independent variables the *Inertial Repeated Entry Mode* and the *Mindful Repeated Entry Mode* instead of the *Inertial Entry Fit* and the *Mindful Entry Fit*. The aim is to provide a direct connection between previous entry mode experience, on the one hand, and growth perspective, on the other hand, without relying on the fit from the first step. This latter variable, indeed, captures the extent to which a firm complies with an entry mode choice that is driven not only by previous entry mode experiences, but also by other covariates. Conversely, by employing directly the variables *Inertial Repeated Entry Mode* and *Mindful Repeated Entry Mode*, we are able to assess the direct effect of different types of previous entry mode experience on the growth perspectives.

The *Inertial Repeated Entry Mode* accounts for the number of previous initiatives that adopted the same mode of entry regardless of previous outcome, while the *Mindful Repeated Entry*

Mode is the number of previous initiatives that adopted the same mode of entry, taking into consideration the outcome of the former initiatives (where failures are accounted with a negative sign, while successes with a positive one and then the two measures are summed)¹³. Following our conceptual framework, the former variable is expected to have a weaker correlation with the dependent variable than the latter on the growth perspective.

Equations (3.a) and (3.b) are estimated in our robustness check and the related results (which are available upon request) substantially confirm our previous findings.

$$Outcome_i = \alpha + \beta \cdot Inertial\ repeated\ entry\ mode_i + \gamma \cdot controls_i + \varepsilon_i \quad (3.a)$$

$$Outcome_i = \alpha + \beta \cdot Mindful\ repeated\ entry\ mode_i + \gamma \cdot controls_i + \varepsilon_i \quad (3.b)$$

Given that the extent to which a firm is willing and able to trigger the learning mechanisms is likely to depend also on the specific roles assigned to the subsidiary or supplier of the new venture, we explored whether the drivers of offshoring have a moderating effect on the inertial and mindful repetition. Specifically, we tested the interaction effect between the entry fits, on the one hand, and the access to talented employees, the cheap labour costs, the co-location with manufacturing activities and the market-seeking drivers, on the other hand. Results, which are available upon request, show that when the offshoring initiatives are driven by the access to talented employees, the impact of both the inertial and mindful entry fit on growth perspective is magnified. A possible explanation is that the access to talents is likely to maximize the transfer of information and knowledge, which is typically embedded in individuals, thus amplifying the effect of the learning mechanisms underlying the inertial and mindful learning on the growth perspective of the new venture. We also found that, when the offshoring initiative is driven by the co-location with manufacturing activities, the effect of mindful learning on growth perspective is strengthened. This is likely to be due to the combination of

¹³ See Diwas, Staats & Gino (2013)

the positive effects arising from the mindful learning approach and from the strong synergies underlying the co-location of manufacturing and business activities.

5. DISCUSSION AND CONCLUDING REMARKS

This paper studies the relationship between different types of repetition of entry choices and growth perspectives of offshoring ventures. Although several works have already identified the temporal interdependence of entry choices, results on whether entry-specific experience fosters learning and, ultimately, growth perspectives are still ambiguous.

The inter-dependence of entry choices has been traditionally attributed to the need of reducing ambiguity as long as greater familiarity with organizational-specific attributes decreases the perceived uncertainty. In our paper we try to identify two main learning mechanisms underlying the repetition of entry choice, i.e. the experiential learning and the creation of new organizational learning both allowing the reduction of liability of foreignness,. However, when learning is inertial, firms tend to be over-confident with the organizational routines adopted in the past and to be subject to lock-in effects and organizational inertia (Petersen et al., 2008). Indeed, we find that the inertial repetition of previous entry modes is not positively associated to the future growth perspectives of offshoring ventures. Conversely, the mindful repetition of previous entry modes is an incremental and self-generating process as firms recombine, develop and apply their expanding organizational routines thus fostering the growth perspectives of their foreign initiatives.

We also find that repetition of captive entry mode displays a more positive effect on the growth perspective than the repetition of outsourcing entry mode, probably due to the more direct and straightforward possibility to transfer information and knowledge associated to the former, which is likely to increase the effectiveness of the learning mechanisms. Our results show that the captive entry mode is able to trigger a positive effect on growth perspective even in case of inertial repetition, while on the opposite side the same type of repetition turns out to be detrimental in case of outsourcing entry mode. Overall, our empirical analysis confirms our theoretical framework, thus providing

further understanding to the relationship between experience, learning and entry mode for foreign initiatives (in the case of business services offshoring).

We believe that our paper contributes to the ongoing debate on entry mode, which is still lively in the IB literature. Indeed, our work departs from the attempt to answer some of the questions raised by the recent revival of the debate on (the need of more) entry mode studies. The selection of the entry mode is one of the key concerns for managers of companies investing abroad; despite the large number of papers on this topic, “we still lack clear tools to help managers to make their choices” (Brouthers, 2013: 14). In addition, following the question posed by Shaver (2013) on whether we need further entry mode studies, Hennart and Slangen (2015) argue that entry mode studies require an evolutionary approach accounting for the role of previous experience. One of the most promising research in this field regards how to choose the entry mode that enables and fosters firms’ competitiveness (Hennart & Slangen, 2015; Martin, 2013). In particular, it is not clear whether firms “merely consider the frequency with which specific modes were chosen previously”, or “take into account the ex post performance of prior choices and hence learn from them”, and, if they learn from prior experience, “from which types of experiences do they learn more” (Hennart & Slangen, 2015: 118). Thus, we add to previous literature on entry modes by inquiring how different types of entry-specific experience lead to different types of learning and, hence, different growth perspectives for the offshoring present initiative. In doing so, we contribute to the managerial and international business literature by showing that, when considering repeated entry modes, Transaction Cost Economics by itself is insufficient to explain MNEs’ critical managerial issues such as the need to create and develop capabilities and processes (Teece, 2014). The Dynamic Capability approach can provide a complementary view by highlighting the role of the learning underlying the repetition of the entry mode. Indeed, previous entry-specific experience might allow decreasing liability of foreignness and overcoming contractual and managerial uncertainties, but it is also likely to lead to organizational inertia, while the development of the most important learning capabilities stems from the iteration of expanding organizational routines leading to a selective and self-reinforcing wisdom (i.e. mindful learning). We also offer novel insights on the different learning process underlying captive and outsourcing.

We finally provide a contribution to one (probably the most important) of the *five* decision making questions concerning offshoring (Hätönen & Eriksson, 2009; Pereira & Malik, 2015), i.e. when to outsource or keep in-house. We show, indeed, the need to take into account the previous entry-specific experience when analysing this strategic decision and we highlight the positive consequences arising from the adoption of an entry choice model that takes into consideration the increasing and decreasing levels of the competitive advantage underlying previous growing and non-growing experiences.

In terms of managerial implications, our results warn practitioners against the risk of adopting inertial repetition of previous entry modes, especially in case of outsourcing. The results of this research suggest that decision makers should carefully inquire the drivers of the success and failures of previous international activities, and particular attention should be granted to the repository of organizational routines (e.g. the workers) and to the mechanisms (e.g. job rotation) that enable the transmission of organizational knowledge across space and time within the firm.

We believe that the present work opens possible future research avenues. First, future works should consider other types of experience (e.g. function-specific, industry-specific, supplier-specific etc.) that might be a source of knowledge and learning enabling the growth of the initiative. Second, future research should consider that not all experiences are equal; older ventures, for instance, might prevent smooth knowledge sharing as long as the context might have deeply changed over time; likewise, the geographic distribution of previous repeated entry modes might also play a role in assessing the type of learning the company can rely on to foster growth. Third, alternative subjective and/or objective dependent variables could be adopted in step (2) in order to investigate other facets of the outcome of foreign ventures. Fourth, future works should disentangle the relationship between the repetition of entry modes and outcome considering also intermediate entry modes such as joint ventures and alliances, and to better disentangle the specific learning arising from each type of entry mode. Fifth, future econometric analysis should be based on panel data in order to study a time-varying phenomenon. Finally, future researches should also clarify the role of unsuccessful initiatives in order to understand if they (i) lead to quit any future offshoring project; (ii) induce to change the

entry mode of the actual or future ventures, or instead; (iii) trigger a learning-from-mistakes process without changing the entry mode structure.

Table 4 - Example of the procedure employed to build the explicative variables of the equations of step

1: all the observations of the example refers to a single firm.

Original data			Equation 1.a		Equation 1.b			
Year of the initiative	Entry mode	Growing Experience	Repeated captive experience	Repeated outsourcing experience	Repeated growing captive experience	Repeated growing outsourcing experience	Repeated non-growing captive experience	Repeated non-growing outsourcing experience
1999	Outsourcing	0	0	0	0	0	0	0
2000	Captive	0	0	1	0	0	0	1
2001	Captive	1	1	1	0	0	1	1
2002	Captive	0	2	1	1	0	1	1
2005	Outsourcing	1	3	1	1	0	2	1

Table 5 - Exploratory Factor Analysis on location variables (Principal Components with Varimax Rotation)

First order construct	Items	Source	Description	Scale	Loading	Alpha
Market Attractiveness	Gross Domestic Product	WCY	Gross Domestic Product	US\$ billions	0.99	0.79
	Gross Fixed Capital Formation	WCY	Total value of acquisitions of domestic firms (net of disposals) of fixed capital during a specific period plus the value increments of non-productive assets generated by productive activities	US\$ billions	0.95	
	Direct Investment Inflows Inward	WCY	Direct Investment Inflows Inward	US\$ billions	0.87	
	Government Consumption Expenditure	WCY	Government Consumption Expenditure	US\$ billions	0.97	
	Household Consumption Expenditure	WCY	Household Consumption Expenditure	US\$ billions	0.97	
Governance Infrastructure	Political Stability and Absence of Violence/Terrorism	WGI	Perception of the likelihood that the government will be destabilized or overthrown by unconstitutional or violent means, including politically-motivated violence and terrorism.	-2.5/2.5	0.88	0.97
	Government Effectiveness	WGI	Perception of the quality of public services, the quality of the civil service and the degree of its independence from political pressures, the quality of policy formulation and implementation, and the credibility of the government's commitment to such policies.	-2.5/2.5	0.86	
	Regulatory Quality	WGI	Perception of the ability of the government to formulate and implement sound policies and regulations that permit and promote private sector development.	-2.5/2.5	0.90	
	Rule of Law	WGI	Perceptions of the extent to which agents have confidence in and abide by the rules of society, and in particular the quality of contract enforcement, property rights, the police, and the courts, as well as the likelihood of crime and violence.	-2.5/2.5	0.89	
	Control of Corruption	WGI	Perceptions of the extent to which public power is exercised for private gain, including both petty and grand forms of corruption, as well as "capture" of the state by elites and private interests.	-2.5/2.5	0.85	

Note: The factor analysis has been performed on 60 countries. The items have been included in the factor analysis as the average value of the period 2004-2011. Higher values reflect better outcomes for all items. WCY stands for World Competitiveness Yearbook, published by the International Institute for Management Development (IMD) of Lausanne (<http://www.imd.org/wcc/>), while WGI stands for Worldwide Governance Indicators, published by the World Bank (<http://info.worldbank.org/governance/wgi/index.asp>).

APPENDIX

Table A: Summary of the variables employed in the model

Variables	Description of the variable
Dependent variables	
Outsourcing (Equations 1.a and 1.b)	Dummy variable resulting from the ORN question: “What is the service delivery model currently used for this offshoring implementation?” <ul style="list-style-type: none"> - Captive (fully owned subsidiary offshore undertakes the activity) (=0) - Outsourced to an international third party provider offshore (e.g. Infosys, IBM) and outsourced to a local third party provider at the offshore location (=1)
Growth Perspective (Equation 2.a and 2.b)	Dummy variable resulting from the ORN question: “What are the plans for this implementation for the next three years?” <ul style="list-style-type: none"> - Expand the activities in the current offshore location (No) (=0) - Expand the activities in the current offshore location (Yes) (=1)
Explanatory variables	
Repeated Captive Experience (Equation 1.a)	Count variable obtained considering the number of 0 in the variable “Outsourcing” before the year of implementation of the initiative
Repeated Outsourcing Experience (Equation 1.a)	Count variable obtained considering the number of 1 in the variable “Outsourcing” before the year of implementation of the initiative
Repeated Growing Captive Experience (Equation 1.b)	Count variable obtained considering the number of 0 in the variable “Outsourcing” when the variable “Growth Perspective” takes value of 1 before the year of implementation of the initiative
Repeated Growing Outsourcing Experience (Equation 1.b)	Count variable obtained considering the number of 1 in the variable “Outsourcing” when the variable “Growth Perspective” takes value of 1 before the year of implementation of the initiative
Repeated Non-Growing Captive Experience (Equation 1.b)	Count variable obtained considering the number of 0 in the variable “Outsourcing” when the variable “Growth Perspective” takes value of 0 before the year of implementation of the initiative
Repeated Non-Growing Outsourcing Experience (Equation 1.b)	Count variable obtained considering the number of 1 in the variable “Outsourcing” when the variable “Growth Perspective” takes value of 0 before the year of implementation of the initiative
Inertial Entry Fit (Equation 2.a)	Fit variable obtained from step 1 (see the methodology)
Mindful Entry Fit (Equation 2.b)	Fit variable obtained from step 1 (see the methodology)
Outsourcing (Equations 2.a and 2.b)	See the dependent variables of equations 1.a and 1.b
Control variables (All equations)	
Country-specific experience	Count variable obtained considering the number of times the company invested in the host country before the year of implementation of the initiative
Firm-level variables	
Medium size	Dummy variable resulting from the ORN question: “What is the total number of employees in your company (domestic only)?” <ul style="list-style-type: none"> - Midsize (500-20,000) (=1 if yes, =0 if no)
Large size	Dummy variable resulting from the ORN question: “What is the total number of employees in your company (domestic only)?” <ul style="list-style-type: none"> - Large size (>20,000) (=1 if yes, =0 if no)
Function-level variables	
High value added function	Dummy variable resulting from the ORN question: “Which of the following functions or processes has your company or organization or division/business unit offshored (including projects that have been terminated)?” <ul style="list-style-type: none"> - Analytical/Knowledge Services (=0) - Call Centre/Customer contact (=0) - Finance/Accounting (=0) - Human Resources (=0) - IT Infrastructure (=0) - Legal Services (=0) - Marketing and Sales (=0) - Software Development (=0) - Supply Chain and Facilities (=0) - Other (=0) - Product Design (=1) - Engineering Services (=1) - Research and Development (=1)
Industry-level variables	
	Dummy variable resulting from the ORN question: “What is the primary industry sector of your company?” <ul style="list-style-type: none"> - Software and IT services (=1)

- Aerospace and Defence (=0)
- Arts, Entertainment and Recreation (=0)
- Automotive (=0)
- Construction (=0)
- Energy, Utilities and Mining (=0)
- Financial Services and Insurance (=0)
- Government/Public Services (=0)
- Healthcare (=0)
- Manufacturing (=0)
- Pharmaceuticals and Life Sciences (=0)
- Professional Services (=0)
- Retail and Consumer Goods (=0)
- Telecommunications (=0)
- Transportation and Logistics (=0)
- Other (=0)

Country-level variables

Cultural Distance	Difference between the home and host cultures computed employing the formula adopted by Kogut and Singh (1988) (Hofstede, 2001)
Governance Infrastructure	First order construct stemming from an exploratory factor analysis on location variables; see table 5 for further details (WGI database)
Market Attractiveness	First order construct stemming from an exploratory factor analysis on location variables; see table 5 for further details (WGI database)
Home country United States	Dummy variable resulting from the ORN question: "In which country is your company headquarters located?" (see table 1 for further information) <ul style="list-style-type: none"> - United States (1) - Rest of the World (0)

Deal-level variables

Access to Qualified Talent	Likert scale variable resulting from the ORN question: "What is the importance of each of the following drivers in considering offshoring this function?" <ul style="list-style-type: none"> - Access to qualified personnel offshore (1-'not important' 5-'very important')
Labour Cost	Likert scale variable resulting from the ORN question: "What is the importance of each of the following drivers in considering offshoring this function?" <ul style="list-style-type: none"> - Labour cost savings (1-'not important' 5-'very important')
Colocation of manufacturing	Likert scale variable resulting from the ORN question: "Why was this particular location chosen?" <ul style="list-style-type: none"> - Co-locating with existing offshore business processes facilities (1-'not important' 5-'very important')
Market Penetration	Likert scale variable resulting from the ORN question: "What is the importance of each of the following drivers in considering offshoring this function?" <ul style="list-style-type: none"> - Access to new markets for products and services (1-'not important' 5-'very important')
Age of the Initiative	Difference between the year of the last release of the survey (2011) and the year of the initiative, the latter resulting from the ORN question: "In what year was this implementation launched?" <ul style="list-style-type: none"> - (Text)
