v2 First published: 22 Nov 2018, 7:1837 (<https://doi.org/10.12688/f1000research.17005.1>)Latest published: 07 Jun 2019, 7:1837 (<https://doi.org/10.12688/f1000research.17005.2>)**Abstract**

InterMine is a data integration and analysis software system that has been used to create both inter-connected and stand-alone biological databases for the analysis of large and complex biological data sets. Together, the InterMine databases provide access to extensive data across multiple organisms. To provide more convenient access to these data from Android mobile devices, we have developed the InterMine app, an application that can be run on any Android mobile phone or tablet. The InterMine app provides a single interface for data access, search and exploration of the InterMine databases. It can be used to retrieve information on genes and gene lists, and their relatives across species. Simple searches can be used to access a range of data about a specific gene, while links to the InterMine databases provide access to more detailed report pages and gene list analysis tools. The InterMine app thus facilitates rapid exploration of genes across multiple organisms and kinds of data.

REVISED Amendments from Version 1

The article has been updated to include further rationale for its development and clarification of the open access conditions for the data and open source nature of the underlying software.

See referee reports

Introduction

InterMine¹ is an open source data integration and analysis software system (license LGPL 2.1) that has been used to create a suite of both inter-connected and stand-alone biological databases for the analysis of large and complex biological data sets. InterMine databases have been developed for the major model organisms budding yeast², nematode worm, fruit fly³, zebrafish, mouse⁴ and rat⁵, (which we will refer to as the Model Organism Database (MOD-) InterMines, together with a human database and databases for plants, bees and wasps⁶, cows⁷, *Medicago truncatula*⁸, mitochondrial proteomics⁹ and drug targets¹⁰ (Table 1; <https://registry.intermine.org/>). Together, the InterMine databases provide access to extensive data across multiple organisms (for full listings of data included see the website for each individual InterMine, Table 1). To provide more convenient

access to these data from Android mobile devices, we have developed the InterMine app¹¹, an application that can be run on any Android mobile phone or tablet.

The InterMine app provides a single interface for data access, search and exploration of the above databases. It can be used to retrieve information on genes and gene lists, and their relatives across species. Simple searches can be used to access a range of data about a specific gene, while links to the InterMine databases provide access to more detailed report pages and gene list analysis tools. Although a number of mobile applications have been developed for the laboratory (see <https://www.bio-compare.com/Editorial-Articles/168745-Ten-Mobile-Apps-for-Biology-Laboratories/>), only a few so far exist for biological databases. Some examples include the YeastGenome app developed by SGD¹², Molecules, for viewing 3D protein structures (<https://itunes.apple.com/us/app/molecules/id284943090?mt=8>) and Pubmed on Tap (<https://itunes.apple.com/us/app/pubmed-on-tap/id301316540?mt=8>) / Pubmed Mobile (<https://play.google.com/store/apps/details?id=com.bim.pubmed&hl=en>) for searching Pubmed and retrieving PDFs. Thus, development of the InterMine app was largely an exploratory exercise as it was not known at the outset what sort of demand there would be for accessing data in such a way, although we were encouraged

Table 1. InterMine databases available through the InterMine app by default. The list can be configured in the app.

ZebrafishMine	Zebrafish	ZFIN	http://zebrafishmine.org/
HymenopteraMine	Various Hymenoptera	University of Missouri	http://hymenopteragenome.org/hymenopteramine

by the success of the yeastGenome app. It is intended that the app provides quick and easy access to information about Genes when researchers may be away from their main computing source, such as when attending a conference or meeting. However, in addition to providing a quick and novel way to access biological data, InterMine app also expands InterMine's functionality in allowing all registered InterMine databases to be searched at once, thus providing a cross-organism view of the term(s) searched.

The app is available from the Google Play Store at <https://play.google.com/store/apps/details?id=org.intermine.app>.

Methods

Data sources

The InterMine app allows users to search a default subset of InterMine data warehouses (Table 1). This list is configurable, and so users are able to refine or add mines to match their interests. See <https://registry.intermine.org> for the full list of known public InterMine instances.

InterMine databases typically integrate data from many resources. For instance BioGRID¹³, IntAct¹⁴, UniProt¹⁵, and can include high quality curated data (from the Model Organism Databases), genome-wide high-throughput data and data from smaller more focused studies (See individual InterMine websites for more details). All the InterMine databases accessible from the app are open source (License LGPL 2.1) and the data within them is free to access and download. Some individual InterMines may have restrictions for commercial use of the data and each individual InterMine should be consulted for its policy. See Table 1 for URLs.

Search and analysis

The InterMine app provides several ways to search and explore the data available, including a keyword search, sets of pre-defined template searches and list analysis functionality. These features are described in more detail in the use case section.

MyMine accounts

InterMine databases allow users to create an account through which they can, between sessions, store lists and searches. The InterMine App therefore allows users to log in to any accounts they hold on the underlying databases, so enabling user-created lists to be accessed.

Favourite genes

Users are also able to mark genes in search results as *favourite*. These genes are stored on the Android device and can be accessed without needing to log in to any of the underlying databases.

Implementation

Communication

The InterMine database design and the webservices used to power the InterMine app have been previously described^{1,16}. The InterMine App draws all data from the RESTful Application Programming Interfaces (APIs) that InterMine databases provide¹⁶. RoboSpice, an Open Source (Apache 2.0 Licence)

Android communications library¹⁷, provides core network communication functionality. Data are loaded asynchronously over HTTP or HTTPS, depending on the preferred protocol of the database being accessed. For performance enhancement, most web service responses are stored on the device if headers state an appropriate cache lifetime.

When the app receives a JSON response from the web service, it transforms the data from a table-structured format to a more hierarchical view, which presents data more effectively on smaller-screened mobile devices.

Authentication

Each InterMine database is discrete and often maintained by different organisations. If a user wishes to authenticate with multiple InterMines - perhaps to view private gene lists stored on different databases - they will need to provide separate authentication details for each InterMine database. However this is only necessary once, as after a user has successfully authenticated in a given InterMine via a username/password pair, the app retrieves and stores an API authentication token. This ensures that the user can authenticate in the future without having to re-enter or store sensitive password details.

All of the user configuration settings and authentication tokens are stored locally on the device via SharedPreferences, Android's dedicated settings storage mechanism¹⁸.

Internal storage

Tabular data, such as favourite genes within the app, are not suited to the key/value pair storage used in SharedPreferences¹⁹, and therefore are stored within an SQLite database on the user's device. Data stored include the InterMine instance the data originated from, the (e.g.) gene's identifiers, description, organism, and genomic coordinates.

Search

Keyword search is available across lists, templates and gene search results. Search results from different databases are presented to the user as a single result set, sorted by the search relevance score generated by each originating database. Search results can be shared via email, instant messaging, and other sharing media in text format, using Android's ACTION_SEND Intent functionality²⁰. Further data export options are available through links to the relevant full InterMine database instance.

Advanced information

InterMine also includes advanced analysis tools - particularly data visualisations - which may not be available via the API. To access the extended information about genes or gene lists, a user can load InterMine's advanced report pages within the app itself. This is implemented via Android's WebView²¹ functionality which allows live web pages to be embedded in an application (for example, Figure 2 shows an example of an embedded InterMine WebView).

Operation

The app is implemented in accordance with Google Material Design²² guidelines, providing a predictable environment

for the user, and also supports Android version 4.0 and above, ensuring it is able to run on over 99% of active Android phones as of November 2018²³.

Use case

The following use case introduces each of the three key features of the InterMine app; Gene search, Templates and Lists with an example of their use. Further details of these InterMine features have been fully described in previous publications from several InterMine databases^{1-3,5,6,8,9}.

Cross-organism gene search

The keyword search simultaneously searches all InterMine databases selected through the *settings* option. Thus, a cross-organism overview of data available for further investigation is provided. Link-outs from the search results to each originating InterMine database provide access to detailed gene report pages. These pages collate information integrated for that gene and typically include functional summaries, ontology annotation, pathway, expression, interaction and disease data and links to additional related data.

As an example, searching for ‘*dopamine*’ returns dopamine-related genes from PhytoMine, MouseMine, HumanMine, TargetMine, FlyMine, RatMine, ZebrafishMine, WormMine, YeastMine, ThaleMine and HymenoperaMine (Figure 1; see Table 1 for urls). Selecting a gene from the results, for instance the human gene *DRD4* (dopamine receptor D4) displays summary information about the gene, with a link to the full gene report available from the HumanMine database. Here we learn, for example, that polymorphisms in the *DRD4* gene are associated with the disorder attention deficit hyperactivity disorder (ADHD) (Figure 2), a condition associated with low dopamine levels. The search results therefore facilitate rapid exploration across multiple organisms and kinds of data.

Template searches

In addition to cross-organism gene search, the InterMine databases provide libraries of pre-built searches, called *template searches*. Such searches provide a user-friendly interface where the parameters for search filters can be specified. These *templates* range from simple searches, such as *for a specified gene (or genes), return the corresponding Gene Ontology terms* (represented as “*Gene → Gene Ontology terms*”), to more complex searches combining data of more than one type, such as “*Tissue + interaction → genes*”, which returns any genes expressed in the specified tissue that also interact with the product of a specified gene. Templates from each InterMine database are available within the InterMine App. The results are provided with a simple keyword search to facilitate further data browsing. For instance, continuing the above dopamine example, we can use a template search to identify genes in *Drosophila* associated with ADHD: on the templates page for the FlyMine database, we find the template “Disease -> Human genes and Orthologues” (Figure 3). This template allows one to specify disease names that *contains “attention deficit”*, and on running the template, this returns the disease *Attention deficit-hyperactivity disorder* along with associated human genes and their

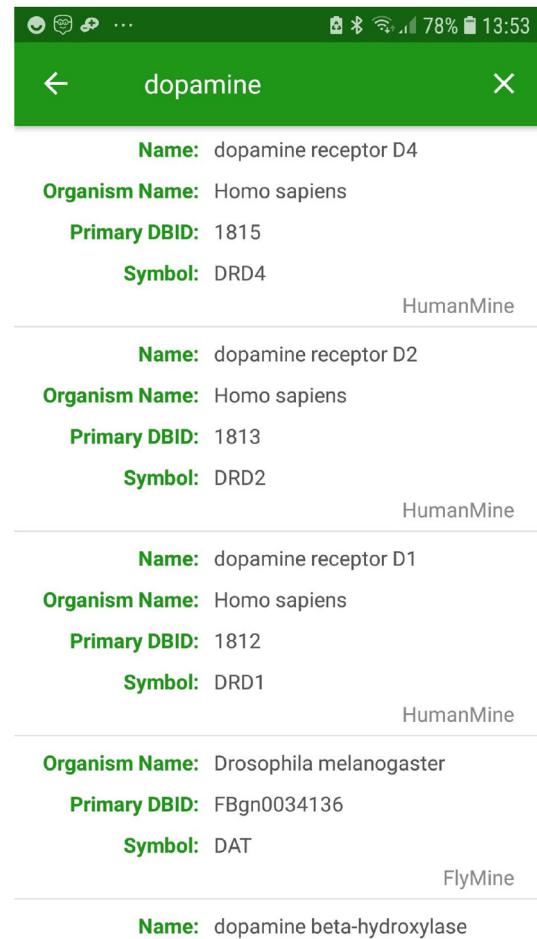

Figure 1. Example keyword search results. A search for dopamine returns genes from PhytoMine, MouseMine, HumanMine, FlyMine, TargetMine, RatMine, ZebrafishMine, YeastMine and ThaleMine. A section of the results from HumanMine and FlyMine is shown.

orthologues from the available InterMine databases. Using the ability to search within the results we are able to verify that the human gene we are interested in (*DRD4*) is associated with this condition, and that this gene has a predicted orthologue in *Drosophila melanogaster*, *FBgn0053517*, *Dop2R* (Figure 4). Through such iterative searching we can continue our investigation of this fly orthologue to identify, for instance, interacting partners, pathway and Gene Ontology annotations.

Lists

InterMine databases are especially suited to the analysis of lists of genes or other entities. Users can create their own lists, which can be stored between sessions if the user has an account for the relevant InterMine database. Again, direct links from lists to the underlying InterMine databases provide access to list analysis tools, for instance enrichment statistics that help identify surprising properties, such as publications that cite an unexpectedly large number of the list members, or GO terms or protein domains that are associated with an unexpectedly large number of list members.

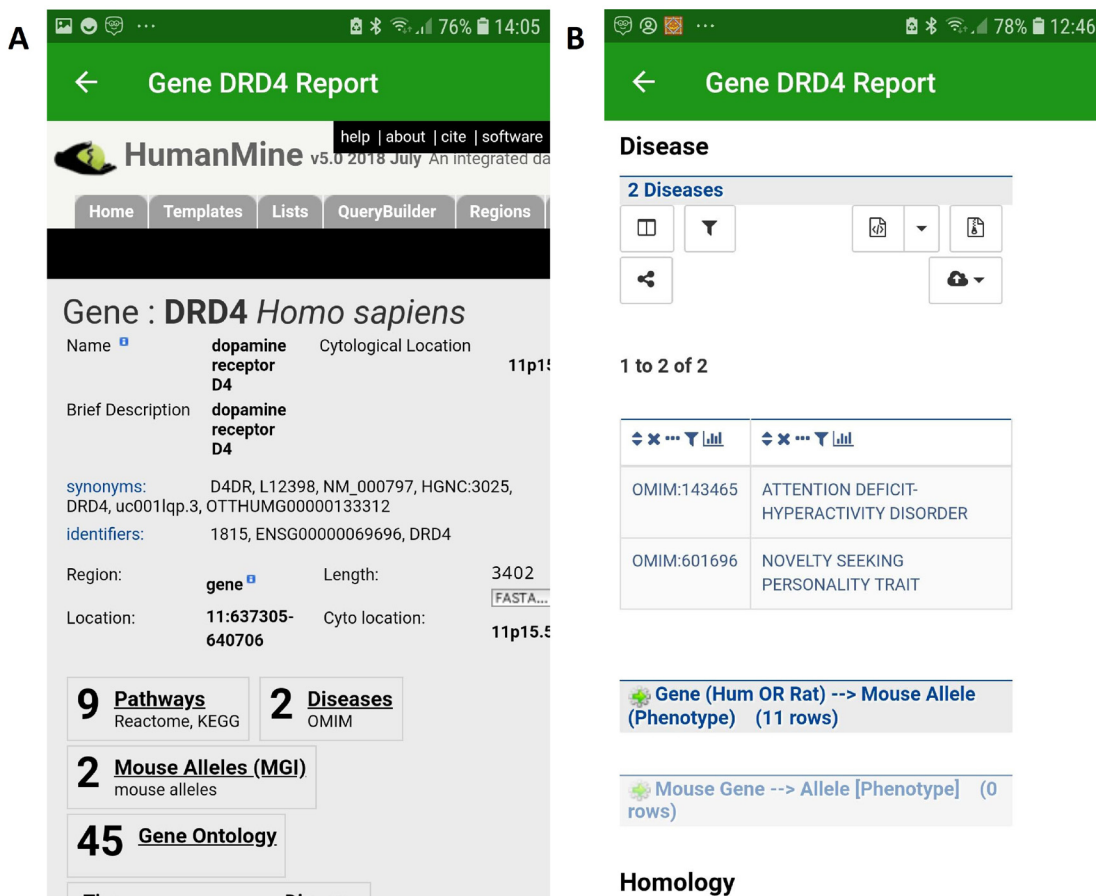

Figure 2. The human DRD4 report page from the HumanMine webapp, displayed in the InterMine app. (a) This view shows the first part of the report page with a summary of the Gene identifiers and data available. (b) This view shows the Disease section of the report page.

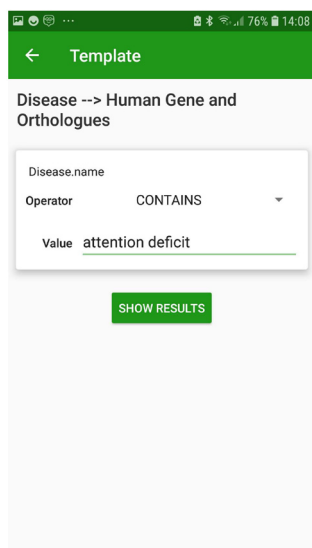

Figure 3. A FlyMine template search, “Disease -> Human genes and Orthologues”. The disease name is an editable constraint, in this case set to search for human genes associated with diseases with a name that “contains” *Attention deficit*, as well as their orthologues.

Public lists, which are typically interesting sets of genes derived from publications and other studies, are often provided by the database operators. For instance, in FlyMine, eleven of the public lists provide sets of genes whose expression increases at defined times during drosophila embryogenesis, as derived from Hooper *et al.*²⁴. Further lists show genes that are expressed at increased levels in various adult fly tissues according to data from the FlyAtlas resource²⁵. Within one of these sets, *PL FlyAtlas_brain_top*, we can identify a set of genes up-regulated in the brain. Checking within this list, we find that the dopamine receptor gene *Dop2R* (FBgn0053517) identified above is present. By following the link to the corresponding list analysis page on the underlying FlyMine website, and examining the enrichment statistics, we find that the *Dop2R* gene is part of a set in which the Gene Ontology term *dopamine receptor signaling pathway* (GO:0007212) occurs unexpectedly frequently (p-value 0.001303, with Holm-Bonferroni correction). It is also apparent that two other fly dopamine receptors, *Dop1R1* (FBgn0011582) and *Dop1R2* (FBgn0266137) are also found in this list (Figure 5).

Conclusions

The InterMine app provides a convenient way of searching for biological information across many model organism and other

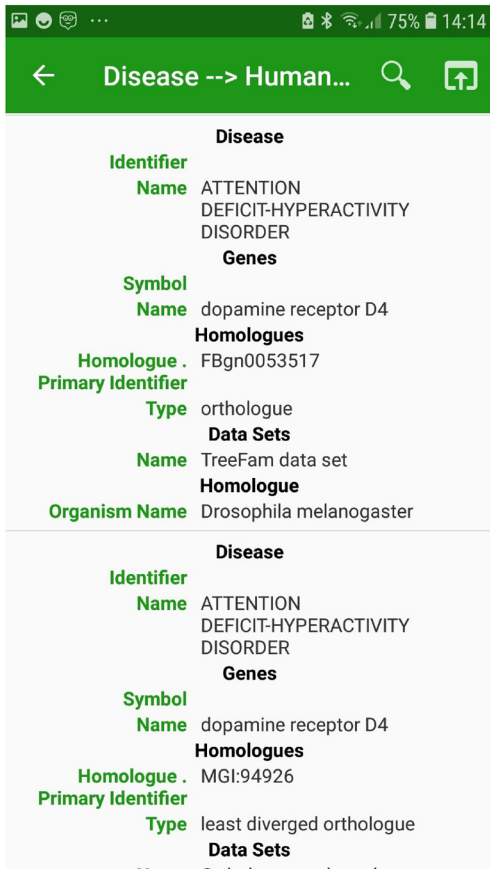

Figure 4. Results from the template “Disease -> Human genes and Orthologues”, with disease constraint set to “contains” Attention deficit, available from FlyMine. Shows the human *dopamine receptor D4* associated with the disease *attention deficit-hyperactivity disorder* and with the *D. melanogaster* orthologue *FBgn0053517, Dop2R*.

databases, allowing an overview of gene function and gene relationships to be pursued. Importantly, the InterMine app reduces the effort required to obtain data available in a range of InterMine databases by removing the need to visit each one individually. Further development of the app is planned, including a single sign-in for all of the InterMine instances through [OAuth2](#); further search and analysis capabilities including extending the keyword search to include all data types (instead of just genes); better cross-InterMine search result ordering; an offline mode with data cached in a local database for access when no internet connection is available, and a more sophisticated query construction capability for more advanced users.

Data availability

All data underlying the results are available as part of the article and no additional source data are required.

Software availability

The InterMine app is available from the Google Play Store: <https://play.google.com/store/apps/details?id=org.intermine.app>.

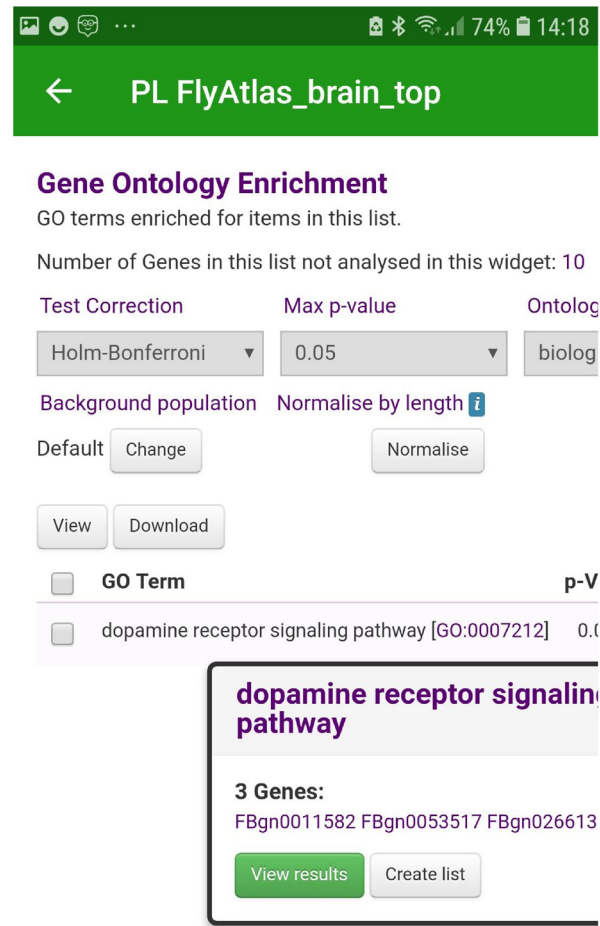

Figure 5. Gene Ontology enrichment analysis of the FlyMine public list PL FlyAtlas_brain_top. A set of three genes (FBgn0011582 (Dpo1R1), FBgn0053517 (dop2R) and FBgn0266137 (Dop1R2) are enriched for the GO term dopamine receptor signaling pathway.

Authors have produced a smart phone app, and I would like to congratulate them for good work.

Here, I provide some comments:

Introduction is brief; there is no background and rationale provided, which can justify the need of such

application. Moreover, there are no details provided of similar smart phone applications and other related platforms (e.g. web, desktop etc.). I would suggest to address these points comprehensively and add comparative analysis of their app with other related applications, including a table based on common and variable features would be helpful.

As authors are interested in publishing their app as a scientific contribution, it's important to have scientific justifications and discussion. At this time paper is more like a brief report.

Methodology; why Android based smart phone app, why not iOS?

Is data behind the app (collection of databases) freely accessible to the users, so they can download, and even verify the results and with other referenced databases? If not, then mention it in the paper, and give reasons for that. As this is an open source work, and data is collected from multiple open sources, its expected to have access to the data linked at the backend.

Authors have mentioned list of databases, it's important to mention licensing information of those database, to avoid any conflict of interest. Moreover, its important to clearly mention it in the conflict of interest section.

Author's contribution are missing, it's also important to list those.

I would suggest to write supplementary material and there explain the app in detail (step-by-step). Guide a new user as to how to get access to the app and how each interface can be used, and what are expected inputs/outputs. Furthermore, if word count restriction does not allow, then further extend supplementary material and provide comprehensive details of software implementation, database design and data workflow with rationale for choosing those options. Make some diagrams (based on software engineering concepts) explaining design and implementation parts.

I would suggest authors to also mention:

1. Current limitations of the app.
2. Current advantages of the app, which signifies it technically and scientifically.
3. What were the major technical, non-technical, and scientific difficulties they have faced while designing and developing this app.
4. Future recommendations, in their view and for other readers.

Regarding Figures; Figure 1 seems isolated. I would rather suggest make one good multi panel Figure, and add 1, 2, 3, 4 to that.

Is the rationale for developing the new software tool clearly explained?

No

Is the description of the software tool technically sound?

Partly

Are sufficient details of the code, methods and analysis (if applicable) provided to allow replication of the software development and its use by others?

Partly

Is sufficient information provided to allow interpretation of the expected output datasets and any results generated using the tool?

Partly

Are the conclusions about the tool and its performance adequately supported by the findings presented in the article?

Partly

Competing Interests: No competing interests were disclosed.

Reviewer Expertise: Bioinformatics

I have read this submission. I believe that I have an appropriate level of expertise to confirm that it is of an acceptable scientific standard, however I have significant reservations, as outlined above.

Author Response 22 May 2019

Rachel Lyne, University of Cambridge, Downing Street, UK

Authors have produced a smart phone app, and I would like to congratulate them for good work.

We thank the reviewer for his detailed comments on the manuscript. We have made several changes to the manuscript and have made further comments below which we hope address the points made:

Here, I provide some comments:

Introduction is brief; there is no background and rationale provided, which can justify the need of such application. Moreover, there are no details provided of similar smart phone applications and other related platforms (e.g. web, desktop etc.). I would suggest to address these points comprehensively and add comparative analysis of their app with other related applications, including a table based on common and variable features would be helpful.

As authors are interested in publishing their app as a scientific contribution, it's important to have scientific justifications and discussion. At this time paper is more like a brief report.

As the development of mobile apps for biology is still in its infancy and as this provided a new and novel way of accessing the data in InterMine, its development was largely exploratory as we did not know at the outset how much demand for the app there would be. The very popular iOS app developed by the Saccharomyces Genome database (utilizing their yeastMine webservice) suggested that this could become a popular way in which data could be accessed (Wong et al; PMID: 23396302). Indeed, the InterMine app has already had well over one hundred downloads and we hope that with continued development this number will increase. We have added a paragraph to the introduction to cover these points.

Methodology; why Android based smart phone app, why not iOS?

An iOS app has been developed independently and will be published separately as the technology is quite different.

Is data behind the app (collection of databases) freely accessible to the users, so they can download, and even verify the results and with other referenced databases? If not, then mention it in the paper, and give reasons for that. As this is an open source work, and data is collected from multiple open sources, its expected to have access to the data linked at the backend.

Search results from within the app can be shared as described under “Search” in the Implementation section. Further export options are available if the full InterMine database is accessed via the app.

We have added a sentence to under “search” of the Implementation section to make this clearer to the reader.

Authors have mentioned list of databases, it’s important to mention licensing information of those database, to avoid any conflict of interest. Moreover, its important to clearly mention it in the conflict of interest section.

All the InterMine databases are open source and provide open access to the data within them. However there are some restrictions for commercial use of some of the data and each individual InterMine should be consulted for its policy. We have added a sentence to the methods section to make this clearer to the reader.

Author’s contribution are missing, it’s also important to list those.

Author contributions were provided in the original paper and are available under the author details.

I would suggest to write supplementary material and there explain the app in detail (step-by-step). Guide a new user as to how to get access to the app and how each interface can be used, and what are expected inputs/outputs. Furthermore, if word count restriction does not allow, then further extend supplementary material and provide comprehensive details of software implementation, database design and data workflow with rational for choosing those options. Make some diagrams (based on software engineering concepts) explaining design and implementation parts.

We feel that the three key aspects of the interface have been fully explained through the use-case and accompanying screenshots. Further details for all aspects of the InterMine interface can be found in previous publications. The InterMine database design and the webservice used to power the InterMine app have also been previously described. The following sentences have been added to the manuscript to direct readers more readily to this information:

Introduction (to use-case)

The following use case introduces each of the three key features of the InterMine app; Gene search, Templates and Lists with an example of their use. Further details of these InterMine features have been fully described in previous publications from several InterMine databases (1,2,3,5,6,8,9).

Added as first sentence under Communication:

The InterMine database design and the webservice used to power the InterMine app have been previously described (1, 14).

Competing Interests: No competing interests were disclosed.

Reviewer Report 10 January 2019

The authors describe the InterMine Android app, which makes data available from InterMine applications on Android devices. Significantly, it is able to combine data from multiple data warehouses, and users can add their own InterMine instances to this list.

The source code is GPL licensed and available on GitHub, and the source code as it was at the time of publication has also been archived.

For this review, unfortunately I did not have access to an Android device, so I assume that the application functions as described.

The app seems to contain a carefully chosen set of core features to enable quick searches, for example by gene or template, and presents combined search results in a streamlined user interface. It is also possible to access gene lists. The WebView feature to display visualisations should also be useful, although most likely the user experience here is harder to control by nature (owing to the different widgets that may be available in InterMine instances being accessed).

I am curious as to how the app would behave if one queries different InterMine instances that have very different response times and displays the combined results. Hopefully, the app would display results incrementally as they are available, instead of waiting for the slowest instance to reply and then combining the results.

The authors have also taken reasonable care to handle authentication details and transmitted information securely.

In summary, the InterMine Android App should be useful for querying InterMine instances on the go from handheld devices, but also for combining data from different instances in a way that, as far as I know, has not been possible until now. I recommend acceptance of this report.

Is the rationale for developing the new software tool clearly explained?

Yes

Is the description of the software tool technically sound?

Yes

Are sufficient details of the code, methods and analysis (if applicable) provided to allow replication of the software development and its use by others?

Yes

Is sufficient information provided to allow interpretation of the expected output datasets and any results generated using the tool?

Yes

Are the conclusions about the tool and its performance adequately supported by the findings presented in the article?

Yes

Competing Interests: No competing interests were disclosed.

Reviewer Expertise: Bioinformatics, software development, genomics

I have read this submission. I believe that I have an appropriate level of expertise to confirm that it is of an acceptable scientific standard.

The benefits of publishing with F1000Research:

- Your article is published within days, with no editorial bias
- You can publish traditional articles, null/negative results, case reports, data notes and more
- The peer review process is transparent and collaborative
- Your article is indexed in PubMed after passing peer review
- Dedicated customer support at every stage

For pre-submission enquiries, contact research@f1000.com
