## Summary

The vascular flora of Significant Landscape Gornji Kamenjak in Istria was investigated in different vegetation periods from 2012 to 2013, and a total of 507 plant taxa (468 species and 39 subspecies) were recorded. Part of them were previously registered, while some are recorded for the first time. The studied area was poorly investigated in the past, therefore there was a need for this study, representing a very detailed floristic survey of the area. The most dominant families were grasses (*Poaceae*, 11.8%), legumes (*Fabaceae*, 10.6%), daisies (*Asteraceae*, 6.5%) and mints (*Lamiaceae*, 5.5%). The domination of therophytes (37.0%) indicates that the climate of Gornji Kamenjak shows a high influence of the Mediterranean climate, followed by hemicryptophytes (30.8%) and geophytes (12.6%). We recorded a total of 11 invasive species across the whole investigated area, as well as the occurrence of 15 endangered and 13 endemic plant taxa. The results of our research of autochthonous vascular flora indicate high richness and diversity of plant species in the studied area.

## Key words

Istria, Premantura, Significant Landscape, vascular flora

## ACKNOWLEDGEMENTS

This study was carried out as the part of the investigation projects “Mapping of vascular flora of Gornji Kamenjak: pilot study and pilot study 2”, supported by the “Public Institution of Kamenjak”. We would like to thank for funding of field research of Gornji Kamenjak and for logistic support during this research. Thanks to Roko Čičmir for the identification of *Ophrys* specimens, and to Slavko Brana for assistance in the field research.

## Introduction

According to the Nature Protection Act (Anonymous, 2013), Gornji Kamenjak is a protected area in the category of Significant Landscape. Gornji Kamenjak is located at the southernmost point of the Istrian Peninsula between two small villages, Premantura in the South and Volme in the North (Fig. 1). It is an integral part of the unity of the local residents known as "Kamenjak", which besides Significant Landscape Gornji Kamenjak also encompasses Significant Landscape Donji Kamenjak and Medulin archipelago. Both areas have been declared as protected in 1996 by the Assembly of the County of Istria (Anonymous, 1996) owing to landscape and natural and cultural values (Nikolić et al., 2010).

The area of Gornji Kamenjak covers 380 ha and includes two islands in the Bay of Medulin; Premanturski and Pomerski Školjic (Fig. 1). The aquatorium surrounding the Kamenjak Peninsula is protected with two adjacent Sites of Community Interest (SCI) as part of the ecological network NATURA 2000: „Akvarij zapadne Istre i Medulinski zaljev“. In addition, the aquatorium is as well protected as Special Protection Area (SPA) for birds.

Gornji Kamenjak was an important strategic area for the Austro-Hungarian army due to its location, hilly terrain and significantly higher altitude in relation to the wider surroundings. This is evidenced by numerous military facilities: tunnels, batteries and bunkers.

Over the territory of Premantura and the surrounding area the prevalent soil type is Eutric Cambisol on Eolian deposits and relict terra rossa, typical and anthropogenized followed by Luvisol, on Eolian deposits, typical and anthropogenized, and Rigosol (Vidaček, 1979; Škorić and Bogunović, 1987). The central part of Gornji Kamenjak with deeper soils is dominated by agricultural landscapes, while on the edges with shallow soil stony grasslands and garigues prevail. Step by step, the coastal zone has been planted with *Pinus halepensis* and vegetation succession took place. The garigue development was slow, due to shallow skeletal soil and arid climate. The investigated area is characterized by a typical Mediterranean climate (Horvat, 1949). Accordingly, recent anthropogenic influence is rather small, excluding the tourists/visitors on beaches in summer (Topić and Šegulja, 2000).

Despite numerous floristic studies carried out across the southern part of Istria (Tommasini, 1873; Freyn, 1877; Perko, 1998; Starmühler, 1998, 2004, 2010; Topić and Šegulja, 2000; Hršak et al., 2011; Vuković et al., 2011, 2013) where more than 500 plant taxa have been recorded in previous investigations, flora of Gornji Kamenjak has not been investigated in detail until presented study.

The aim of this study was to perform an updated inventory of the vascular flora and flora mapping, as well as analysis of plant diversity of Gornji Kamenjak, which would benefit species protection and conservation management of this ecologically valuable area.

## Materials and methods

Floristic study of vascular flora of Gornji Kamenjak was carried out from 2012 to 2013 during the entire vegetation seasons. The standard methods for flora inventory and mapping were used according to Nikolić (2006) and Nikolić et al. (1998) within seven MTB 1/64 fields. Geographical coordinates for each locality were recorded using Garmin vista e-Trex GPS (Fig. 1).

Nomenclature of plant taxa follows the Flora Croatica Database (Nikolić, 2018). Families, genera, species and subspecies are listed

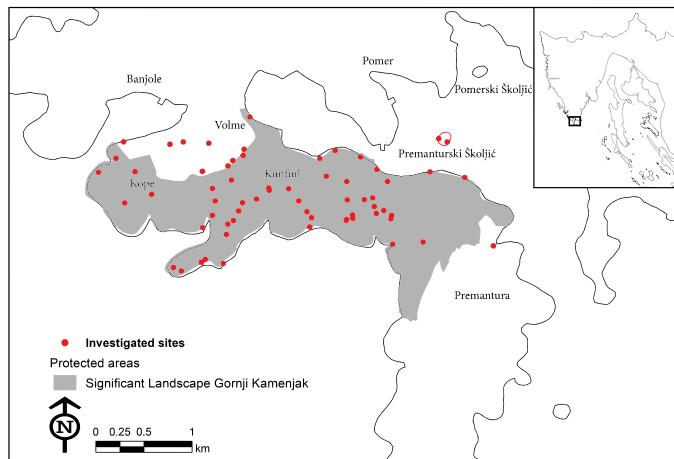

Figure 1. Geographical position of Significant Landscape Gornji Kamenjak with investigated sites

in alphabetical order and organized according to higher systematic units according to Nikolić (2013).

The analysis of life forms was conducted according to Raunkiaer (1934), Horvat (1949) and Pignatti (1982). In the floristic list, life forms are marked with the following abbreviations: *Chamaephyta* (Ch), *Geophyta* (G), *Hemicryptophyta* (H), *Phanerophyta* (Ph), *Therophyta* (T) and *Hydrophyta* (Hy).

Endemic taxa (End) are determined according to Nikolić et al. (2015) and Flora Croatica Database (Nikolić 2018), while invasive species (Inv) are determined according to Boršić et al. (2008). The status of endangered plant taxa: critically endangered (CR), endangered (EN), vulnerable (VU), least concern (LC), near threatened (NT) and data deficient (DD) was assigned according to Nikolić and Topić (2005) and Flora Croatica Database (Nikolić, 2018).

For the purpose of floristic mapping of the Significant Landscape Gornji Kamenjak, we obtained permission from the Ministry of Environment and Nature Protection to collect plant material. Collected herbarium specimens are deposited in ZAGR herbarium and are accessible through the Virtual Herbarium (<http://herbarium.agr.hr>) according to Bogdanović et al. (2016).

## Results

During the floristic research of Gornji Kamenjak a total of 507 vascular plant taxa were recorded, out of which 13 plant taxa are endemic, 15 taxa are endangered (CR, EN, VU) and 11 taxa are classified as invasive plant species (Tab. 1).

### Analysis of vascular flora

A total of 507 taxa (468 species and 39 subspecies) were recorded within 291 genera and 77 families (Tab. 2). Across the area of Gornji Kamenjak, five species from *Monilophyta* section and 503 taxa from *Spermatophyta* section were identified. Four species belong to the group of *Gymnospermae* and 461 species and 39 subspecies to the group of *Angiospermae*. There was a greater representation of the *Eudicotyledonae* (three times more) compared to the *Liliaceae*. Although less represented by the number of species, the group of *Liliaceae* occupied a large part of the open areas of Gornji Kamenjak.

**Table 1.** The list of vascular plant taxa identified in the area of Gornji Kamenjak in Istria. Abbreviations are given for life forms: *Chamaephyta* (Ch), *Geophyta* (G), *Hemicryptophyta* (H), *Phanerophyta* (Ph), *Therophyta* (T) and *Hydrophyta* (Hy); status: critically endangered (CR), endangered (EN), vulnerable (VU), least concern (LC), near threatened (NT), data deficient (DD); and endemic (End) and invasive plant taxa (Inv)

Table 2. Flora analysis of Gornji Kamenjak area by systematic categories

Section	<b>Monilophyta</b>		<b>Spermatophyta</b>		
	Psilotidae	Polypodiidae	Gymnospermae	Eudicotyledonae	Angiospermae
Subclass			Pinidae		Lilianae
Family	1	1	2	60	13
Genus	1	1	2	221	66
Species	1	4	4	349	111
Subspecies				33	6
Total taxa (%)	5 (0.9%)		4 (0.8%)	381 (75.2%)	117 (23.0%)

The representation of genera, species and subspecies within the respective families is shown in Fig. 2. According to the number of species and subspecies, the most represented were *Poaceae* (11.8%), followed by *Fabaceae* (10.6%), *Asteraceae* (6.5%) and *Lamiaceae* (5.5%).

Figure 2. Proportion of the most abundant families recorded in the area of Gornji Kamenjak.

Analysis of life forms (Fig. 3) shows a high ratio of therophytes (37.0%) and hemicryptophytes (30.8%), followed by percentage of geophytes (12.6%).

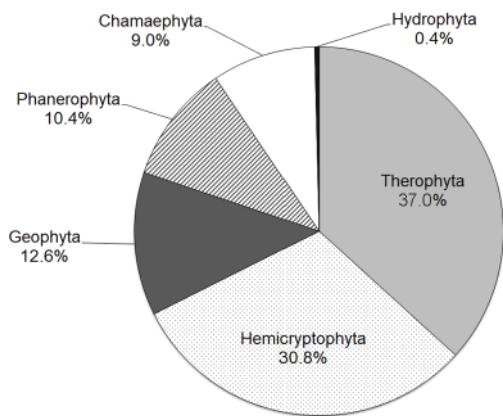

Figure 3. Spectrum of life forms recorded in the area of Gornji Kamenjak.

## Discussion

The flora of the wider area of Donji Kamenjak, known also as Rt Kamenjak in the southernmost part of Istria was previously investigated by numerous authors including Tommasini (1873), Freyn (1877), Topić (1994, 1997), Topić et al. (1998), Starmühler (1998, 2004, 2010), Topić and Šegulja (2000) and Vuković et al. (2011, 2013). Former studies have identified more than 430 vascular plant taxa in this area. On the other hand, flora of the adjacent Gornji Kamenjak has never been a subject of systematic investigation and we here provide for the first time a detailed flora inventory that consists of a total of 507 vascular plant taxa recorded during this study.

The flora richness of the investigated area is high, in comparison to several Croatian islands, islets and reefs along the eastern Adriatic coast (Nikolić et al., 2008), especially considering the size of the area. The vascular flora of Gornji Kamenjak has a high biodiversity in terms of number of plant species; 507 plant taxa (468 species and 39 subspecies) have been recorded across the area of only 380 hectares. These results are comparable to Mediterranean territories of similar size, which are characterized by a great variety of habitats and a rather complex geomorphology (Gianguzzi et al., 2006; Minissale et al., 2007; Nikolić et al., 2008).

The domination of therophytes (187 species, 37.0%) indicates that the climate of the area of Gornji Kamenjak is typical Mediterranean (Horvat, 1949). Furthermore, therophytes were also well represented within the grassland communities indicating the aridity and Mediterranean climate of this region (Rauš and Šegulja, 1983; Tomašević, 2006) and considerable anthropogenic influence (Mitić et al., 2007). The high percentages of observed therophytes (37.0%) and hemicryptophytes (30.8%), congruent with other studies (Bogdanović and Mitić, 2003; Sciandrello et al., 2014), can be related to the considerable diffusion of seminatural habitats, such as dry grasslands, originated by anthropogenic disturbance, and uncultivated land. The area of Gornji Kamenjak can be compared with the North Adriatic islands (Cres, Krk and Pag) investigated

by Ljubičić (2012), as well as with some other Mediterranean areas (Giardina et al., 2007; Raimondo et al., 1994; Sciandrello et al., 2014), where there are not significant differences between percentages of life form spectrum. Habitats with low intensity of sheep grazing or high intensity of land abandonment are often subjected to the process of progressive succession where phanerophytes suppress therophytes (Škornik et al., 2010; Ljubičić, 2012). It is interesting that sheep grazing is not present in the area of Gornji Kamenjak. However, we found a high percentage of therophytes similarly to other Mediterranean regions (Melendo et al., 2003; Ljubičić, 2012). The share of 12.6% of geophytes is mostly related to plant taxa that grow in forest communities in the area of Gornji Kamenjak.

Intentional or unintentional human activity in recent periods helped in spreading invasive adventive plants in the autochthonous flora. Like other European countries, Croatia has been facing the increased problem of invasive alien species. Up to now, 74 invasive alien plant taxa have been recorded in Croatia (Boršić et al., 2008; Nikolić et al., 2014; Nikolić, 2018). On the area of Gornji Kamenjak, 11 invasive taxa were recorded (*Ailanthus altissima*, *Amaranthus retroflexus*, *Conyza canadensis*, *Datura stramonium*, *Euphorbia prostrata*, *Phytolacca americana*, *Robinia pseudoacacia*, *Sorghum halepense*, *Veronica persica*, *Xanthium spinosum* and *Xanthium strumarium* ssp. *italicum*), accounting for 14% of the total number of invasive plant taxa in Croatia. The fact that these invasive taxa are found in a relatively small area points out to the scale and is currently not posing any serious threats to the studied area. The species *Ailanthus altissima* is very aggressive due to the toxins that prevent growth of other species (allelopathy). This species usually forms dense populations, however we observed only a few individuals within the area of Gornji Kamenjak. The species *R. pseudoacacia* also represents a threat to the surrounding vegetation where it grows because of great dominance over indigenous taxa, while *Xanthium* taxa occurs sporadically in agricultural habitats such as vegetable gardens. Other invasive taxa such as *Amaranthus retroflexus*, *Conyza canadensis*, *Phytolacca americana*, *Sorghum halepense* and *Veronica persica* occur along roads, paths, abandoned agricultural land and similar ruderal habitats of Gornji Kamenjak.

According to the IUCN (International Union for Conservation of Nature) Threats Classification Scheme a total of 15 endangered plant species (Tab. 1), included in the online Red book of vascular flora of Croatia (Nikolić, 2018), were recorded in flora of Gornji Kamenjak. The species *Papaver hybridum*, *Lathyrus ochrus* and *Ophioglossum lusitanicum* are critically endangered (CR), *Carex divisa*, *C. extensa*, *Lemna gibba*, *Ophrys apifera* and *Orchis italica* are endangered (EN), while *Desmazeria marina*, *Orchis papilionacea*, *O. simia*, *O. tridentata*, *Parapholis incurva*, *Salsola soda* and *Suaeda maritima* are vulnerable (VU). In Croatian flora the largest share of endangered species belongs to the family *Orchidaceae* (Hršak, 2000; Bogdanović, 2004; Delforge, 2006; Nikolić, 2018), as well as in the wider area of Kamenjak (Kranjčev, 2005; Vuković, et al. 2011; 2013). Vuković et al. (2013) have found a very rare species *Ophrys speculum* growing along the macadam road running through the garrigue vegetation of the order *Cisto-Ericetalia H-ić*. 1958 in the area of Donji Kamenjak. Unfortunately, this species was not recorded during our study in the area of Gornji Kamenjak. Due to its specific climatological position, habitat diversity and other influences we can expect that the investigated area harbors more species than currently recorded.

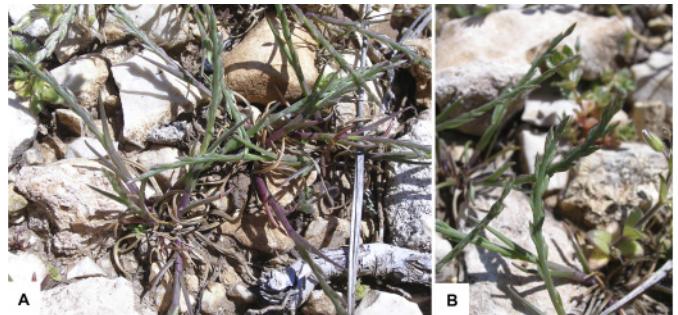

**Figure 4.** Flowers of stenoendemic orchids, A – *Ophrys incantata* Devillers et Devillers-Tersch, B – *Ophrys untcjii* (M.Schulze) P.Delforge and C – *Ophrys medea* Devillers et Devillers-Tersch.

The area of Donji Kamenjak is known as one of the “Orchid islands” in Croatia due to high orchid richness (Kranjčev, 2005). Among others, we have found three stenoendemic orchids (*Ophrys incantata*, *Ophrys untcjii* and *Ophrys medea*) with very restricted distribution. The species *O. incantata* (Fig. 4A) is known from central and southern Dalmatia and our finding in southern Istria represents new locality outside the currently known Croatian distribution. The species *O. untcjii* (Fig. 4B) is described and already known from Istria and Kvarner archipelago, nevertheless the occurrence in the flora of Gornji Kamenjak is rather rare and sporadic, as well as the occurrence of the species *O. medea* (Fig. 4C).

**Figure 5.** Inflorescence of *Orchis × gennarii* Rchb. f.

The analysis of vascular flora of Gornji Kamenjak shows the occurrence of some very rare plant species in Croatian flora. Among them is a hybrid taxon *Serapias × todaroi* (=*S. parviflora* × *S. lingua*) of which we found only few individuals in the region of Kunfin. This is a very rare finding of this species for the Croatian flora. This taxon has been previously recorded at the islands of Mljet, Dugi Otok and Korčula (Šegota et al., 2012; Jeričević and Jeričević, 2016).

**Figure 6.** *Desmazeria pauciflora* Merino, A – habitus, B – inflorescence.

Another hybrid orchid worth mentioning is *Orchis × gennarii* (=*O. morio* × *O. papilionacea*), of which we found only few individuals (Fig. 5) in the vicinity of the village Volme at Monte Cope. A population of grass species *Desmazeria pauciflora* (Fig. 6A, B) we found in four localities in whole area of Kamenjak (Valmižje, Crvene stine, Premanturski školjci and islet Ceja). This species has been found and cited as *Catapodium pauciflorum* (Merino) Brullo, Giusto, Miniss. & Spamp. for the first time in Croatian flora by Skelin et al. (2014) on the islet of Zečevo in Hvar archipelago. Afterwards it was recorded in Sabuniće near the town of Nin and on the islands of Vis and Pag (Nikolić 2018). *Desmazeria pauciflora* is morphologically very similar to *D. marina* but it differs in having smaller spikelets (4.5-5.5 x 1.4-2 mm) that are closely appressed to inflorescence rachis (Brullo et al. 2003). The occurrence of *D. pauciflora* could be expected elsewhere along the eastern Adriatic coast and islands. During this floristic research we have found and confirmed a very rare and critically endangered fern species *Ophioglossum lusitanicum* that has not been recorded previously by Topić and Šegulja (2000) during their thoroughly botanical research of the southernmost part of Kamenjak but was recorded in recent times on Donji and Gornji Kamenjak by Brana et al. (2014). *Ophioglossum lusitanicum* was already noted for Kamenjak by Freyn (1877) and confirmed later by Blečić and Mayer in 1975 based on herbarium specimen that is deposited in Herbarium ZA-5527. Our study confirmed the occurrence of this very rare species in the area of Kunfin.

### Conclusion

In the period from 2012 to 2013 flora inventory of Significant Landscape Gornji Kamenjak was carried out and a total of 507 vascular plant taxa (468 species and 39 subspecies) were recorded. The studied area was poorly investigated in the past, therefore there was the need for this study, representing a very detailed floristic survey of the area. This research confirmed the recent findings by other authors of very rare and critically endangered species of ferns (*Ophioglossum lusitanicum*). Prevalence of Mediterranean floral elements and the dominance of therophytes indicate influence of typical Mediterranean climate on the area of Gornji Kamenjak. The flora richness of the investigated area was high, particularly in comparison with several islands, islets and reefs along the eastern Adriatic coast, especially considering the size of the areas. Given that, on the area of Gornji Kamenjak we have recorded 11 invasive, 13 endemic and 15 endangered plant taxa. Endangered plant taxa belong primarily to orchid family.
