Knowledge and Attitudes of Primary Health Care Dentists Regarding Oral Cancer in Brazil

Znanje i stajališta primarnih doktora dentalne medicine o oralnom karcinomu u Brazilu

Stomatološki fakultet Državnog sveučilišta Paraíba, João Pessoa, Brazil

Abstract

Objective: The aim of this study was to evaluate the knowledge and attitudes of dentists working in Primary Health Care Units from a Brazilian city, regarding oral cancer. **Materials and methods:** A prospective, cross-sectional, epidemiologic survey was performed. Seventy-one dentists from Primary Health Care Units were contacted at their workplace, and participated of the study. Data were collected through a self-administered questionnaire of 31 multiple-choice questions addressing the main clinical features and risk factors for oral cancer. The questionnaire was divided into two sections: questions related to general data and self-perception of the participants regarding personal knowledge of oral cancer, and objective questions related to general information on oral cancer (clinical features, characteristics, traits, and risk factors). The data were tabulated and analyzed by descriptive statistics. **Results:** Participants were mostly females (81.5%), less than 40 years of age (57.7%), who underwent training 10–20 years ago (47.9%). Most respondents (66.2%) considered their level of knowledge about oral cancer to be satisfactory. However, only 26.8% of them felt that they were able to carry out diagnostic procedures for oral cancer. Most of them (95.8%) were interested in participating in training courses on Oral Diagnostics; 56.3% of them reported not having received any training or guidance on how to conduct an examination to detect oral cancer during undergraduate training. **Conclusions:** These findings are consistent with previous reports and point to the need for new public policies to enable early diagnosis of oral cancer and a review of training in Oral Diagnostics in dental schools.

Introduction

Oral cancer is a global health care problem (1). There were nearly 300,000 new cases and 145,000 deaths due to oral cancer in the world, reported in 2012 (2), making it one of the ten most common cancers (3). In Brazil, during 2018–2019, new onset oral cancer is estimated to occur in 11,200 men and 3,500 women. This corresponds to an estimated risk of 10.86 new cases per 100,000 men and 3.28 per 100,000 women (4).

The most common risk factors associated with oral cancer are tobacco and alcohol consumption (5). However, regardless of the risk factors associated with the disease, the most important factor for patient survival is the stage at which it is diagnosed (2). Most oral cancers are diagnosed when clinical signs and/or symptoms are already present. At this point, about 70% of all cases are in an advanced clinical stage (6). Lack of patient information combined with inadequately trained health professionals are usually the main reasons for

Uvod

Rak usne šupljine je globalni zdravstveni problem (1). Istaknimo da je diljem svijeta zabilježeno gotovo 300 tisuća novih slučajeva i 145 tisuća smrti zbog raka usne šupljine (2), što ga čini jednim od deset najčešćih vrsta (3). U Brazilu, tijekom 2018. i 2019. godine procjenjuje se da je od toga raka oboljelo 11 200 muškaraca i 3 500 žena. To odgovara procijenjenom riziku od 10,86 novih slučajeva na 100 000 muškaraca i 3,28 na 100 000 žena (4).

Konsumacija duhana i alkohola najčešći su rizični čimbenici povezani s oralnim karcinomom (5). No bez obzira na to, najvažniji čimbenik za preživljavanje bolesnika jest faza u kojoj se bolest dijagnosticira (2). Naime, većina oralnih karcinoma dijagnosticira se kada su se klinički znakovi i/ili simptomi već pojavili. Trenutačno je oko 70 % svih slučajeva u napredovaloj kliničkoj fazi (6). Nedovoljno informiranje pacijenata, u kombinaciji s neodgovarajuće sposobljenim zdravstvenim osobljem, glavni su razlozi za kasnu dijagno-

the late diagnosis of oral cancer (7). Late diagnosis also occurs because patients of low socioeconomic status have limited access to primary health care (8).

The known risk behaviors associated with oral carcinogenesis demonstrate that more than 80% of all oral cancers can be prevented. According to studies around the world, the preventive strategy, especially in developing countries, the goal should be primary prevention, including health education and corrective lifestyle interventions (1-3, 5-7, 9).

A recent Spanish study revealed that the knowledge and attitudes of health care dentists can contribute significantly to changing the current scenario in oral cancer (1). An evaluation of the knowledge and attitudes about oral cancer among these professionals is of utmost importance. The information gained from such evaluation may help to assess the need to implement public policies aimed at continued education. Therefore, the aim of the present study was to evaluate the knowledge and attitudes towards oral cancer of Brazilian dentists from Primary Health Care Units.

Subjects and methods

The present study was carried out in the Primary Health Care Units (named Family Health Units), in Recife, Pernambuco, Brazil. A prospective, cross-sectional, epidemiologic survey was performed. The study was approved by the Local Research Ethics Committee (protocol 1# 29642314.6.0000.5208).

The study was performed between February and June, 2015. The sample included 71 dentists, who consented to participate and answered the questionnaire. All participants were selected by random sampling. The dentists who were confined to administrative tasks were excluded from the survey.

The registry and data collection were carried out by means of a self-administered questionnaire of 31 multiple-choice questions addressing the main clinical features and risk factors for oral cancer. The questionnaire was divided into two sections: 1) Questions related to general and demographics data of the participants (age, gender, time since graduation, attitudes towards patients with oral cancer and self-perception regarding personal knowledge of oral cancer); and 2) Objective questions related to general information on oral cancer (clinical features, characteristics, traits, and risk factors). The questionnaire also included questions related to potentially malignant disorders of the oral cavity.

The objective of the present study was explained before the study was commenced. Data confidentiality and the right to leave the study at any point of time were ensured by consenting to the terms of the study. All participants signed the informed consent form. In addition to verbal explanation and description of the study, each participant received a copy of the informed consent form along with the self-administered questionnaire.

A statistical analysis was carried out using the SPSS ver. 20.0 software (Statistical Package for the Social Sciences, Chicago, IL, USA). Descriptive statistics were obtained for variables including age, time since graduation, attitudes to-

zu te bolesti (7). Kasna dijagnoza pojavljuje se i zato što bolesnici niskoga socijalno-ekonomskoga statusa imaju ograničen pristup primarnoj zdravstvenoj zaštiti (8).

Poznata rizična ponašanja povezana s karcinogenezom usta pokazuju da se više od 80 % svih oralnih karcinoma može spriječiti. Prema istraživanjima diljem svijeta, preventivna strategija, posebno u zemljama u razvoju, trebala bi imati kao cilj primarnu prevenciju, uključujući zdravstvenu izobrazbu i korektivne intervencije u vezi s načinom života (1-3, 5-7, 9).

U nedavnom španjolskom istraživanju istaknuto je da znanje i stajališta zdravstvenog osoblja i doktora dentalne medicine mogu znatno pridonijeti promjeni trenutačnog stanja povezanog s tom bolešću (1). Procjena znanja i stajališta o oralnom raku među tim stručnjacima iznimno je važna. Informacije dobivene takvom procjenom mogu pomoći u procjeni je li potrebna provedba novih javnih zdravstvenih smjernica sa svrhom nastavka obrazovanja. Zato je cilj ovog istraživanja bio procijeniti znanje i stajališta o oralnom raku brazilskih stomatologa u jedinicama primarne zdravstvene zaštite.

Ispitanici i metode

Ovo prospektivno, presječno, epidemiološko istraživanje obavljeno je u jedinicama primarne zdravstvene zaštite (pod nazivom Obiteljske zdravstvene jedinice) u Recifeu (Pernambuco, Brazil). Odobrio ga je Odbor za etička istraživanja na lokalnoj razini (protokol br. 29642314.6.0000.5208).

Istraživanje je trajalo od veljače do lipnja 2015. godine. Uzorak je obuhvatio 71 doktora dentalne medicine. Svi su pristali sudjelovati te su odgovorili na pitanja u upitniku. Odabrani su slučajnim uzorkovanjem. Doktori dentalne medicine ograničeni na administrativne poslove, bili su isključeni iz istraživanja.

Registar i prikupljanje podataka provedeno je na temelju upitnika u kojemu je bilo 31 pitanje s višestrukim izborom o glavnim kliničkim značajkama i rizičnim čimbenicima kad je riječ o raku usne šupljine. Upitnik je bio podijeljen na dva dijela – na pitanja o općim i demografskim podatcima sudionika (dob, spol, koliko je godina proteklo od završetka studija, stajališta o pacijentima s oralnim karcinomom i samopercepcija o osobnom znanju o oralnom raku) te na objektivna pitanja koja se odnose na opće informacije o oralnom raku (klinička obilježja, karakteristike, svojstva i rizični čimbenici). Upitnik je sadržavao i pitanja o potencijalno malignim poremećajima u usnoj šupljini.

Cilj ovog istraživanja objašnjen je prije njegove provedbe. Povjerljivost podataka i pravo na odustajanje od sudjelovanja u bilo kojem trenutku, osiguravali su pristanak na uvjete studije. Svi sudionici potpisali su informirani pristanak. Uz verbalno objašnjenje i opis studije, svaki sudionik dobio je i kopiju obrasca za informirani pristanak zajedno s upitnikom koji su sami popunili.

Statistička analiza obavljena je softverom SPSS ver. 20.0 (statistički paket za društvene znanosti, Čikago, IL, SAD). Deskriptivna statistika dobivena je za varijable dob, godine protekle od diplomiranja, stajališta o pacijentima s oralnim karcinomom i samopercepcija o osobnom znanju o toj

wards patients with oral cancer, and self-perception regarding personal knowledge of oral cancer (clinical characteristics, traits, and risk factors). The variables of "time since graduation" and "self-perception regarding personal knowledge about oral cancer" were compared to other variables using the chi-square test ($p \leq 0.05$).

Results

General characteristics of the studied population

The study sample comprised 71 dentists, 58 females (81.7%) and 13 males (18.3%). Most of them were 40 years old or less (31 – 57.7%). Thirty-four (47.9%) participants had graduated 10-20 years ago, 28 (39.4%) had graduated more than 20 years ago, and 9 (12.7%) had graduated less than 2 years ago. There were only 3 smokers (4.2%) among the participants.

Clinical features of oral cancer

Regarding the clinical findings related to oral cancer, 47 (66.2%) participants indicated that squamous cell carcinoma was the most common type of oral cancer. Fifty-one (71.9%) contributors indicated that the tongue and the floor of the mouth were the most frequent sites of oral cancer, while 7 (9.8%) did not respond to this question. Sixty-six dentists (93%) indicated that oral cancer most commonly affects patients over 40 years old, and 54 (76.1%) also indicated that oral cancer is more frequently diagnosed at an advanced clinical stage (Table 1).

Table 1 Distribution of the answers regarding clinical features of oral cancer
Tablica 1. Raspodjela odgovora o kliničkim obilježjima oralnog raka

Variables • Varijable		n (%)
What is the most common type of oral cancer? • Koji je najčešći oblik raka usne šupljine?	Squamous Cell Carcinoma • Karcinom pločastih stanica Mucoepidermoid carcinoma • Mukoepidermoidni karcinom Ameloblastoma • Ameloblastom Kaposi Sarcoma • Kaposijev sarkom Lymphoma • Limfom Do not know • Ne znam	47 (66.2) 3 (4.2) 3 (4.2) 2 (2.8) 1 (1.4) 15 (21.1)
What is the most common site affected by the oral cancer? • Koja je najčešća lokalizacija raka usne šupljine?	Tongue/Floor of mouth • Jezik/dno usne šupljine Buccal mucosa • Obrazna sluznica Palate • Nepce Gum • Desni Do not know • Ne znam	51 (71.9) 8 (11.2) 3 (4.2) 2 (2.8) 7 (9.8)
What is the most age group affected by the oral cancer? • Koja je dobna skupina najčešće zahvaćena rakom usne šupljine?	Under 18 years • Mlada od 18 godina Between 18 and 40 year • Između 18 i 40 godina Above 40 years • Starija od 40 godina Do not know • Ne znam	0 (0.0) 2 (2.8) 66 (93.0) 3 (4.2)
What is the most frequent clinical stage in which the oral cancer is diagnosed? • Koja je najčešća klinička faza u kojoj se dijagnosticira rak usne šupljine?	Initial • Početna Advanced • Uznapredovala Do not know • Ne znam	7 (9.9) 54 (76.1) 10 (14.0)
Which of the following diseases are commonly related with the development of oral cancer? • Koje su od sljedećih bolesti obično povezane s razvojem raka usne šupljine?	Leukoplakia • Leukoplakija Candidiasis • Kandidijaza Stomatitis <i>Pemphigus vulgaris</i> Geographic tongue • Geografski jezik Do not know • Ne znam	61 (85.9) 4 (5.6) 3 (4.2) 1 (1.4) 0 (0.0) 2 (2.8)

bolesti (kliničke karakteristike, svojstva i rizični čimbenici). Varijable godine protekle od diplomiranja i samopercepcija o osobnom znanju o oralnom raku uspoređene su s ostalim varijablama korištenjem hi-kvadrat testa ($p \leq 0.05$).

Rezultati

Opće karakteristike ispitivane populacije

Uzorak je obuhvatio 71 doktora dentalne medicine – 58 žena (81,7 %) i 13 muškaraca (18,3 %). Najviše ih je bilo u dobi od 40 godina ili manje (31 – 57,7 %). Njih 34 (47,9 %) diplomiralo je prije 10 do 20 godina, 28 (39,4 %) prije više od 20 godina, a 9 (12,7 %) prije manje od dvije godine. Među sudionicima bila su samo tri pušača (4,2 %).

Kliničke značajke raka usne šupljine

Kad je riječ o kliničkim nalazima o raku usne šupljine, 47 (66,2 %) sudionika izjavilo je da je karcinom pločastih stanica najčešći oblik oralnoga raka. Da su jezik i dno usne šupljine najčešća mjesta na kojima se pojavljuje ta bolest, naveo je 51 sudionik (71,9 %), a 7 (9,8 %) nije odgovorilo na to pitanje. Dodajmo da je 66 doktora dentalne medicine (93 %) zaokružilo odgovor da oralni karcinom najčešće pogđa pacijente starije od 40 godina, a 54 (76,1 %) naznačilo je da se rak oralne šupljine najčešće dijagnosticira u kasnoj kliničkoj fazi (tablica 1.).

Risk factors associated with oral cancer

Most participants indicated that tobacco (71, 100%), alcohol (70, 98.6%) consumption, exposure to sunlight (69, 97.2%), and family history (68, 95.8%) were risk factors for oral cancer. Emotional stress, and low intake of fruits and vegetables were indicated as risk factors by 56 (78%) and 42 (59.2%) participants, respectively. Ill-fitting prostheses (63, 88.7%), deficient oral hygiene (56, 78.9%), and the presence of tooth decay (56, 78.9%) were also identified as risk factors for oral cancer. Oral sex and parenteral drug abuse were identified as risk factors for oral cancer by 36 (50.7%) and 15 (21.1%) dentists, respectively (Table 2).

Rizični čimbenici povezani s oralnim karcinomom

Većina sudionika navela je da su duhan (71 – 100 %), alkohol (70 – 98,6 %), izloženost sunčevu svjetlu (69 – 97,2 %) i obiteljska anamneza (68 – 95,8 %) rizični čimbenici za rak usne šupljine. Emocionalni stres i nizak unos voća i povrća istaknulo je kao rizične čimbenike 56 (78 %), odnosno 42 (59,2 %) sudionika. Loše proteze (63 – 88,7 %), nedovoljna higijena usne šupljine (56 – 78,9 %) i karijes (56 – 79,9 %) također su označeni kao rizični čimbenici. Oralni seks i parenteralnu zlouporabu droga istaknuto je 36 (50,7 %), odnosno 15 (21,1 %) doktora dentalne medicine (tablica 2.).

Tablica 2. Apsolutna i relativna raspodjela odgovora o rizičnim čimbenicima za rak usne šupljine
Table 2 Absolute and relative distribution of the answers regarding risk factors for oral cancer

Variables • Varijable		n (%)
Parenteral drug abuse • Parenteralna primjena droga	Yes • Da	15 (21.1)
	No • Ne	56 (78.9)
Alcohol consumption • Konzumacija alkohola	Yes • Da	70 (98.6)
	No • Ne	1 (1.4)
Tobacco consumption • Konzumacija duhanskih proizvoda	Yes • Da	71 (100.0)
	No • Ne	0 (0.0)
Family history of cancer • Obiteljska anamneza raka	Yes • Da	68 (95.8)
	No • Ne	3 (4.2)
Emotional stress • Emocionalni stres	Yes • Da	56 (78.9)
	No • Ne	15 (21.1)
Low vegetables and fruits intake • Nizak unos voća i povrća	Yes • Da	42 (59.2)
	No • Ne	29 (40.8)
Oral sex • Oralni seks	Yes • Da	36 (50.7)

	No • Ne	8 (11.3)
Deficient oral hygiene • Loša oralna higijena	Yes • Da	56 (78.9)
	No • Ne	15 (21.1)
Presence of decay teeth • Zubi s karijesom	Yes • Da	53 (74.6)
	No • Ne	18 (25.4)
Solar exposure • Izloženost suncu	Yes • Da	69 (97.2)
	No • Ne	2 (2.8)
Hot food and drink • Vruća hrana i piće	Yes • Da	33 (46.5)
	No • Ne	38 (53.5)

Clinical practice related to the oral cancer

When asked about performing physical examination to identify the presence of oral lesions, 70 (98.6%) of them confirmed this practice at the first appointment. Regarding further course of action when an oral lesion was identified, 67 (94.4%) participants stated that they would refer the patient to a specialist in Oral Diagnosis, two (2.8%) would refer to a specialized hospital, and two (2.8%) would confirm the diagnosis themselves.

Knowledge of oral cancer, interest, and perception

On analysis of the general features of oral cancer, 47 (66.2%) participants considered their knowledge to be adequate. Nineteen (26.8%) dentists stated that they were confident to carry out diagnostic procedures related to oral cancer. Most study participants (60 – 84.5%) pointed out that their

Klinička praksa povezana s oralnim karcinomom

Na pitanje obavljaju li fizikalni pregled kako bi ustanovili postoje li oralne lezije, njih 70 (98,6 %) potvrđno je odgovorilo već na prvom sastanku. Kad je riječ o dalnjim postupcima nakon što je identificirana oralna lezija, 67 (94,4 %) sudionika izjavilo je da bi uputili pacijenta specijalistu za oralnu dijagnozu, dva (2,8 %) bi ga poslala u specijaliziranu bolnicu, a dva (2,8 %) bi sami potvrdili dijagnozu.

Poznavanje raka usne šupljine, interes i percepcija

Kad je riječ o analizi općih svojstava oralnog karcinoma, 47 (66,2 %) sudionika smatralo je da je njihovo znanje adekvatno. Njih 19 (26,8 %) izjavilo je da su sposobni obaviti dijagnostičke postupke vezane za rak usne šupljine. Većina je (60 – 84,5 %) istaknula da njihovi pacijenti nisu bili dobro

patients were not well informed about preventive procedures and general features of oral cancer.

Forty (56.3%) participants stated that they never received any information related to the diagnosis of oral cancer during undergraduate training. Thirty-six (50.7%) participants had not enrolled in any continued education course during the previous two years. However, the majority (68, 95.8%) expressed interest in undergoing continued education courses in the future. Moreover, 70 (98.6%) participants acknowledged the importance of dentists in the prevention and early diagnosis of oral cancer.

Statistical analysis did not show any significant association between the time since graduation and self-perception regarding personal knowledge about oral cancer and the other variables ($p = 0.2$).

Discussion

The incidence of and death rate due to oral cancer can be minimized if adequate measures are undertaken to enable prevention, early diagnosis, and expeditious treatment (10). In general, dentists are expected to have adequate knowledge on the risk factors and clinical features of oral cancer, regardless of its implementation in public health or private practice. However, there are some indications, such as the persistence of oral cancer as a major health problem, that this assumption may not have been fulfilled in routine primary care dentistry or in private practices.

Most of the participants were 40 years old or younger. Therefore, it is a young population having a long professional career ahead, which requires further education, to enable prevention and early diagnosis of oral cancer. With respect to professional experience, 47.9% of participants were between 10 and 20 years, 39.4% were more than 20 years, and 12.7% were up to 2 years since graduation. Based on the above information regarding professional experience, it would appear that a significant number of participants would be confident of carrying out clinical procedures to diagnose oral cancer. However, only 26% of dentists expressed such confidence. The absence of association between duration since graduation and the other variables studied shows that some participants assumed to have a good knowledge of oral cancer even though their responses to the questionnaire did not support this claim.

In the present study, 66.2% of the participants pointed out that squamous cell carcinoma was the most common type of oral cancer, while 33.8% did not know or answered incorrectly. Another study revealed that 18.4% of surveyed dentists were unaware of the most common type of oral cancer (11). This is of concern, because it shows a lack of knowledge of the biological behavior of the tumor, apart from likelihood of compromising the initial oral examination of patients.

The primary health care dentists correctly pointed out that the tongue and the floor of the mouth were the most common sites for oral cancer, with most tumors affecting patients above 40 years old, which is similar to the findings from other studies (12). Among the potentially malignant disorders, leukoplakia is the most prevalent, with a 5% ma-

informirani o preventivnim postupcima i općim značajkama oralnoga karcinoma.

Da nikada nisu dobili nikakve informacije vezane za dijagnozu oralnoga karcinoma tijekom dodiplomskog obrazovanja, navelo je 40 ispitanika (56,3%). Njih 36 (50,7%) nije sudjelovalo ni u kojem obliku nastavka izobrazbe tijekom protekle dvije godine. No većina (68 – 95,8%) je istaknula da je zainteresirana za daljnju edukaciju. Štoviše, 70 (98,6%) sudionika izjavilo je da je doktor dentalne medicine iznimno važan u prevenciji i ranoj dijagnostici oralnoga karcinoma.

Statistička analiza nije pokazala značajnu povezanost između godina proteklih od završetka studija i samopercepcije o osobnom znanju o oralnom raku i drugim varijablama ($p = 0,2$).

Raspis

Učestalost i smrtnost zbog raka usne šupljine mogu se znatno smanjiti ako se poduzmu odgovarajuće mjere kako bi se omogućila prevencija, rana dijagnoza i brzo liječenje (10). Od doktora dentalne medicine općenito se očekuje odgovarajuće znanje o rizičnim čimbenicima i kliničkim značajkama oralnoga karcinoma, bez obzira na primjenu u javnom zdravstvu ili privatnoj praksi. No postoje neke naznake, poput postojnosti raka usne šupljine kao velikoga zdravstvenog problema, da ta prepostavka možda nije ispunjena u rutinskoj stomatologiji primarne zaštite ili u privatnoj praksi.

Većina sudionika bila je u dobi od 40 godina ili mlađa. Dakle, upravo je pred tom mladom populacijom duga profesionalna karijera koja zahtijeva daljnju izobrazbu kako bi se omogućila prevencija i rano otkrivanje raka usne šupljine. Kad je riječ o profesionalnom iskustvu, u 47,9 % slučajeva ono bilo je između 10 i 20 godina, u 39,4 % slučajeva bilo je iznad 20 godina, a 12,7 % do dvije godine. Na temelju tih podataka o profesionalnom iskustvu čini se da bi znatan broj sudionika bio siguran u obavljanju kliničkih postupaka za dijagnosticiranje oralnog karcinoma. No samo je 26 % doktora dentalne medicine izrazilo takvo stajalište. To što nema povezanosti između godina proteklih od završetka studija i drugih ispitivanih varijabli, pokazuje da neki sudionici pretpostavljaju da dobro poznaju oralni karcinom, iako njihovi odgovori u upitniku ne podupiru tu tvrdnju.

U ovom istraživanju je 66,2 % ispitanika odgovorilo da je karcinom pločastih stanica najčešći oblik oralnoga karcinoma, a 33,8 % nije znalo ili je odgovorilo netočno. U jednom drugom istraživanju 18,4 % ispitanih doktora dentalne medicine nije znalo za najčešći oblik oralnoga karcinoma (11). To zabrinjava jer pokazuje nedostatak znanja o biološkom ponašanju tumora, a to može ugroziti početni oralni pregled pacijenata.

Doktori dentalne medicine primarne zdravstvene zaštite ispravno su istaknuli da su jezik i dno usne šupljine najčešća mjesta za pojavu raka usne šupljine, pri čemu je većina tumora uočena kod bolesnika starijih od 40 godina, što je slično nalazima u drugim istraživanjima (12). Među potencijalno malignim poremećajima najčešća je leukoplakija, sa stopom maligne transformacije od 5 % (13). Zadaća doktora dental-

lignant transformation rate (13). The role of the dentist is of utmost importance in the diagnosis and education of the patient with leukoplakia. The present study showed that 85.9% of the participants identified leukoplakia as the condition most commonly associated with oral cancer, as observed in another survey (12).

The first preventive measure against oral cancer relies on the awareness of patients and dentists about the risk factors associated with the disease (2). Alcohol and tobacco consumption are the most important risk factors related to oral cancer, with an incremental risk when both are used concomitantly (14–16). The proportion of smokers (80%) among patients with oral cancer is two to three times higher than in the general population, with increasing risk depending on the number of cigarettes smoked per day and the duration of smoking. Similarly, one third of men with oral cancer have a history of heavy alcohol consumption (14). Similar to previous studies (11, 13, 15), alcohol (98.6%), smoking (100%) and exposure to sunlight (97.2%) were the most frequent risk factors stated by the participants. In the current survey, low intake of fruits and vegetables was pointed out as a risk factor for oral cancer by 59.2% of participants. Epidemiological studies have shown a two-fold increase in the risk of oral cancer with low intake of fruits and vegetables (17). Moreover, Toporcov et al. (18) showed that consumption of fruit and vegetables can mitigate the harmful effects of smoking. Thus, education in dietary habits may also be an important factor in the prevention of oral cancer.

Deficient oral hygiene (78.9%) and tooth decay (74.6%) were pointed out as risk factors for oral cancer by a large number of participants. Even though other studies have revealed similar results (19–21), it is difficult to establish a cause and effect relationship between these factors and the development of oral cancer. There is no agreement in the literature whether deficient oral hygiene and the presence of tooth decay may expose the patient to a higher risk of developing oral cancer. Similar reasoning can be applied to ill-fitting prostheses, identified as a risk factor for oral cancer by 88.7% of participants in the present study. Some authors suggest that microorganisms present in the oral cavity produce carcinogenic acetaldehydes that potentiate the effects of alcohol and tobacco (22,23). Moreover, most of the Brazilian populations do not have access to adequate dental treatment; hence, poor general oral hygiene is usually observed (24).

The Human Papilloma Virus (HPV) causes approximately 5.2% of cancers in humans, including rectal, genital, oropharyngeal, and cervical cancer. While epidemiology and correlation between HPV infection and oropharyngeal cancer is well established, many factors remain unknown regarding the association between HPV oral infection and oral cancer. Despite the limited knowledge of the epidemiology, natural history and prevention of HPV oral infection, studies show that the infection is sexually transmitted and is related to the development of some cases of oral cancer (25). It is established that approximately 5% of cases of oral cancer are related to HPV infection (26, 27). Although the incidence of HPV-induced oral cancer is low, dentists can guide patients on the risks of unprotected oral sex. On the other hand, the

ne medicine neobično je važna u dijagnostici i edukaciji bolesnika s leukoplakijom. U ovom istraživanju uočeno je da 85,9 % ispitanika identificira leukoplakiju kao stanje koje se najčešće povezuje s oralnim karcinomom, što je zapaženo i u drugom istraživanju (12).

Prva preventivna mjera u vezi s rakom usne šupljine oslanja se na svijest pacijenata i doktora dentalne medicine kad je riječ o rizičnim čimbenicima povezanim s tom bolešću (2). Konzumacija alkohola i duhana najvažniji su rizični čimbenici povezani s rakom usne šupljine, a opasnost se povećava ako se oboje koristi istodobno (14 – 16). Udio pušača (80 %) među bolesnicima s oralnim karcinomom je od dva do tri puta veći negoli u općoj populaciji, a rizik se povećava ovisno o broju popušenih cigareta na dan i trajanju pušenja. Slično tomu, trećina muškaraca s oralnim karcinomom ima povijest teške konzumacije alkohola (14). Slično dosadašnjim istraživanjima (11, 13, 15), alkohol (98,6 %), pušenje (100 %) i izloženost sunčevoj svjetlosti (97,2 %) bili su najčešći rizični čimbenici koje su naveli sudionici. U sadašnjem istraživanju, 59,2 % ispitanika upozorilo je na nizak unos voća i povrća kao na rizični čimbenik za oralni rak. U epidemiološkim studijama istaknuto je dvostruko povećanje rizika od raka usne šupljine ako se ne jede dovoljno voća i povrća (17). Štoviše, Toporcov i suradnici (18) dokazali su da konzumacija voća i povrća može ublažiti štetne učinke pušenja. Zato izobrazba o prehrani također može biti važan čimbenik u prevenciji raka usne šupljine.

Neodgovarajuću higijenu usne šupljine (78,9 %) i zubni karijes (74,6 %) navela je kao rizični čimbenik većina sudionika. Iako su u drugim istraživanjima dobiveni slični rezultati (19 – 21), teško je utvrditi uzročno-posledičnu vezu između tih čimbenika i razvoja oralnog karcinoma. U literaturi nema suglasja mogu li neodgovarajuća oralna higijena i karijes izvrsgnuti pacijenta većem riziku od nastanka te bolesti. Slično razmišljanje može se primjeniti i na loše izrađene proteze koje je 88,7 % sudionika u ovoj studiji navelo kao rizični čimbenik. Neki autori sugeriraju da mikroorganizmi u usnoj šupljini proizvode kancerogene acetaldehide koji pojačavaju djelovanje alkohola i duhana (22, 23). Istaknimo da većina brazilske populacije nema pristup odgovarajućem stomatološkom liječenju i zato se općenito uočava loša opća oralna higijena (24).

Humani papiloma virus (HPV) uzrokuje oko 5,2 % karcinoma kod ljudi, uključujući rektalni, genitalni i orofaringealni rak te rak grlića maternice. Dok je epidemiologija i korelacija između infekcije HPV-om i raka ždrijela dobro poznata, mnogi čimbenici ostaju nepoznati kad je riječ o povezanosti između oralne infekcije HPV-om i oralnoga karcinoma. Unatoč ograničenom znanju o epidemiologiji, prirodnoj povijesti i prevenciji HPV-a, studije pokazuju da se infekcija prenosi spolno i da je povezana s pojavom nekih slučajeva raka usne šupljine (25). Utvrđeno je da je oko 5 % slučajeva oralnoga karcinoma povezano s infekcijom HPV-om (26, 27). Iako je učestalost oralnih karcinoma induciranih HPV-om niska, doktori dentalne medicine mogu obavijestiti pacijente o opasnostima od nezaštićenoga oralnog seksa. S druge strane, ispitanu populaciju bila je pod pogrešnim dojmom da je emocionalni stres rizičan za rak usne šu-

populations surveyed were under the mistaken impression that emotional stress is a risk factor for oral cancer, a finding similar to that observed in another survey (10).

Most oral cancers are diagnosed at an advanced clinical stage (6). In the current study, 76.1% of the participants were aware of this fact, which is similar to the findings observed in another survey (10). Diagnostic delay may be attributed to factors associated with the patient (patient delay) or practitioners (professional delay). Although it is variable, patient delay has been reported to be approximately six months. It is estimated that patient delay of more than 3 months significantly worsens the prognosis (28). The two main components of national cancer control programs are information for the public and professionals. However, in the present study, 84.5% of the participants stated that patients are not well informed on the preventive and diagnostic aspects of oral cancer. Other factors related to the diagnostic delay of oral cancer were the limited access to primary health care for patients of low socioeconomic status, and irregular dental follow-up (8). The diagnostic delay is also related to the lack of knowledge of dentists regarding identification of oral lesions. The professional delay varies between one and five months. Oral examinations are limited to teeth and gums, and lack of knowledge of oral mucosal lesions, may be factors associated with delay in diagnosis of oral cancer (28). In the current survey, 66.2% of the dentists indicated a satisfactory knowledge regarding this; however, only 26.8% of them stated that they were confident enough to carry out diagnostic procedures related to oral cancer, as reported in other studies (3,11). It is important to point out that dentists should undertake the responsibility of their role in the prevention and diagnosis of oral cancer. The majority of dentists (98.6%) reported that their participation is essential in these processes.

During undergraduate training, 56.3% of dentists stated that they did not receive any information on how to perform a clinical examination to screen for oral cancer. These data are alarming, which suggests that during undergraduate training, adequate emphasis should be put on identifying oral lesions, especially oral cancer. The dentist should make a difference by combining theoretical knowledge with clinical skills to facilitate the early diagnosis of oral cancer. Hence, undergraduate training in dentistry and continued education courses should focus on the identification and prevention of oral cancer and other potentially malignant disorders. These measures are of utmost importance in decreasing morbidity and mortality due to oral cancer (29). Currently, the need for continued education is a prerequisite for professional performance, since new information and technological advances make the knowledge acquired during undergraduate training outdated within a short period of time (30). There is a need for regular education programs meant for updating the knowledge level of professionals (29, 30). However, 50.7% of participants stated that they did not subscribe to a continued education course for more than two years. On the other hand, most of them (95.8%) showed a keen interest in such courses in the future, as was previously mentioned (2).

pljine, što je nalaz sličan onome koji je uočen u drugom istraživanju (10).

Većina oralnih karcinoma dijagnosticira se u već napredovaloj kliničkoj fazi (6). U trenutačnom istraživanju, 76,1 % sudionika bilo je svjesno te činjenice, a slično je zabilježeno i u drugom istraživanju (10). Dijagnostičko kašnjenje može se pripisati čimbenicima povezanim s pacijentom (kašnjenje pacijenta) ili praktičarima (profesionalno kašnjenje). Iako je varijabilno, zabilježeno je da pacijenti obično kasne približno šest mjeseci. Procjenjuje se da kašnjenje bolesnika dulje od tri mjeseca znatno pogoršava prognozu (28). Dvije glavne stavnice nacionalnih programa za kontrolu raka su informacije za javnost i profesionalce. No u ovom istraživanju je 84,5 % ispitanika izjavilo da pacijenti nisu dobro obaviješteni o preventivnim i dijagnostičkim aspektima raka usne šupljine. Ostali čimbenici povezani s kašnjenjem dijagnoze raka usne šupljine bili su ograničen pristup primarnoj zdravstvenoj skrbi za pacijente s niskim socijalno-ekonomskim statusom i nedovito praćenje stanja zubala (8). Dijagnostičko kašnjenje povezano je i s nedostatkom znanja doktora dentalne medicine o identifikaciji oralnih lezija. Profesionalna kašnjenja variraju od jednoga do pet mjeseci. Oralni pregled ograničen samo na zube i desni, osim nedostatka znanja o lezijama oralne sluznice, može biti čimbenik povezan s odgodom dijagnoze oralnoga karcinoma (28). U ovom istraživanju 66,2 % doktora dentalne medicine pokazalo je zadovoljavajuće znanje o tome, no samo je 26,8 % izjavilo kako su dovoljno sigurni da mogu obaviti dijagnostičke postupke povezane s rakom usne šupljine, a to je istaknuto i u drugim istraživanjima (3, 11). Važno je dodati da bi doktori dentalne medicine trebali preuzeti odgovornost za svoju zadaću u prevenciji i dijagnozi oralnog karcinoma. Većina njih (98,6 %) izjavila je da je u tim procesima njihovo sudjelovanje ključno.

Prema riječima 56,3 % doktora dentalne medicine, tijekom dodiplomskog studiranja nisu dobili nikakve smjernice o tome kako obaviti klinički pregled za otkrivanje raka usne šupljine. Ti podatci zabrinjavaju i sugeriraju da bi se tijekom studija trebalo staviti težiste na otkrivanje i određivanje oralnih lezija, posebno raka usne šupljine. Doktor dentalne medicine trebao bi pritom kombinirati teorijsko znanje i kliničku vještina kako bi se olakšala rana dijagnoza raka usne šupljine. Zato bi se dodiplomski studij dentalne medicine i tečajevi kontinuirane izobrazbe trebali usredotočiti na identifikaciju i prevenciju raka usne šupljine i drugih potencijalno malignih poremećaja. Te su mjere najvažnije za smanjenje morbiditeti i smrtnosti zbog te bolesti (29). Trenutačno je potreba za kontinuiranom izobrazbom preduvjet za profesionalnu učinkovitost zato što nova znanja i tehnološki napredak čine vrlo brzo znanje stečeno tijekom dodiplomskog usavršavanja zastarjelim (30). Postoji potreba za redovitim edukacijskim programima namijenjenima ažuriranju razine znanja stručnjaka (29, 30). No 50,7 % sudionika izjavilo je da se dulje od dvije godine nisu upisali ni na jedan tečaj cje洛ivotne izobrazbe. S druge strane, većina njih (95,8 %) pokazala je zanimanje za takve tečajeve u budućnosti, kao što je već uočeno (2).

Conclusion

In this study, dentists from Primary Health Care Units in Brazil did not express a level of confidence required for the diagnosis of oral cancer. In addition, a questionnaire with open-ended questions could reveal even more worrying results. This calls for a change in educational and training programs on oral cancer during undergraduate dentistry courses. This will result in an increased number of trained professionals, capable of correctly diagnosing this disease. Moreover, public health care policies need to be revised to reduce morbidity and mortality due to this disease.

Sažetak

Cilj: Željeli su se procijeniti znanje i stajališta o oralnom raku brazilskih doktora dentalne medicine u jedinicama primarne zdravstvene zaštite. **Materijali i metode:** Provedeno je prospektivno, presječno, epidemiološko istraživanje. Sa 71 doktorm dentalne medicine iz primarne zdravstvene zaštite kontaktiralo se na njihovu radnom mjestu i svi su se složili sa sudjelovanjem u istraživanju. Podaci su prikupljeni na temelju upitnika s 31 pitanjem s višestrukim izborom o glavnim kliničkim značajkama i rizičnim čimbenicima za karcinom usne šupljine. Upitnik je bio podijeljen u dva dijela – na pitanja koja se odnose na opće podatke i samopoimanje sudionika o osobnom znanju o oralnom karcinomu te na objektivna pitanja povezana s općim informacijama o oralnom karcinomu (klinička obilježja, karakteristike, svojstva i rizični čimbenici). Podatci su upisani u tablice i analizirani deskriptivnom statistikom. **Rezultati:** Sudionici su bile uglavnom žene (81,5 %) mlade od 40 godina (57,7 %) koje su završile školovanje prije 10 do 20 godina (47,9 %). Većina (66,2 %) smatra da je razina njihova znanja o oralnom karcinomu zadovoljavajuća. No samo 26,8 % istaknulo je da može obaviti dijagnostičke postupke u slučaju raka usne šupljine. Većina (95,8 %) je bila zainteresirana za sudjelovanje na tečajevima ospozobljavanja za postavljanje oralne dijagnoze, a 56,3 % izjavilo je da nisu bili ni na kakvoj edukaciji ili nisu dobili smjernice o tome kako obaviti pregled za otkrivanje raka usne šupljine tijekom dodiplomskog školovanja. **Zaključak:** Ovi nalazi u skladu su s dosadašnjim izvješćima i upućuju na to da su potrebne nove javnozdravstvene smjernice kako bi se omogućila rana dijagnoza raka usne šupljine i obavila revizija kurikula o oralnoj medicini u školama dentalne medicine.

Zaključak

U ovom istraživanju doktori dentalne medicine iz jedinica primarne zdravstvene zaštite u Brazilu nisu pokazali razinu znanja potrebnu za dijagnosticiranje oralnoga karcinoma. Uz to, upitnik s otvorenim pitanjima mogao bi otkriti još zabrinjavajućih rezultata. To zahtijeva promjenu u studijskim i nastavnim programima o oralnom raku tijekom dodiplomskog studija dentalne medicine. To će rezultirati povećanim brojem profesionalaca sposobnih za ispravno dijagnosticiranje te bolesti. Štoviše, javne zdravstvene smjernice treba revidirati kako bi se smanjili morbiditet i smrtnost zbog te bolesti.

Izvori financiranja

Ovo istraživanje nije dobilo nikakvu finansijsku potporu.

Zahvale

Ovo istraživanje predstavljeno je na 42. brazilskom kongresu orane medicine i oralne patologije (Brazilian Congress of Oral Medicine and Oral Pathology) u Manausu, u pokrajini Amazoniji od 4. do 8. srpnja 2016. godine.
